SUPPLEMENT

TO THE

ENCYCLOPÆDIA.

Electrometer.

ELECTROMETER, is an instrument which measures the quantity of electricity in any electrified body. The most common electrometers are described in the article ELECTRICITY *(Encycl.)*, n° 27, and 182—233. A very valuable one is likewise described in n° 85. of the article ELECTRICITY in this Supplement; but there are still two electrometers, of which we have hitherto given no account, though they are of such value, that to pass them unnoticed would be unpardonable. The first, which is by much the most accurate and delicate instrument of the kind that we have seen, was invented by Mr Coulomb, and is adapted to ascertain the smallest quantity of redundant electricity. The second is a late invention of Mr Cuthbertson, the ingenious improver of the air-pump, and is employed only to measure the charge of large jars and batteries.

ELECTROMETER, by *Mr Coulomb* of the Royal Academy of Sciences at Paris, described in the Memoirs for 1785.

Mr Coulomb had made some experiments in examination of Dr Hooke's theory of springs "*ut tensio sic vis*;" and found, that it was surprisingly exact, in regard to the force necessary for twisting elastic wires. Having suspended a nicely turned metal cylinder by a fine wire in the direction of its axis, and having given it several turns, and left it to regain its natural position, he observed, that it performed all its revolution of untwisting and twisting in times precisely equal, whether these oscillations were of a few degrees, or consisted of several revolutions. He thence concluded, that the force with which the wire endeavoured to regain its natural position was exactly proportional to its distance from it. Engaged, soon after, by order from the Minister of Marine, in an examination of the phenomena of the mariner's compass, he took this method of suspending his needles, in order to obtain exact measures of the forces which caused them to deviate from the magnetic meridian. He made some observations with needles so suspended; which are highly valuable to the philosopher engaged in that study. When his success in this research had fully gratified his wishes, he turned his thoughts to the examination of the law of electric action by the help of an electrometer suspended in the same manner. It is constructed as follows:

Plate XXVII.

ABDC (fig. 1.) represents a glass cylinder, 12 inches in diameter and in height. This is covered by a glass plate fitted to it by a projecting fillet on the under surface. This cover is pierced with two round holes of $1\frac{1}{4}$th inches in diameter. One of them *f* is in the centre, and it receives the lower end of the glass tube *f h*, of 24 inches height, which is fixed in the hole with a cement made of sealing-wax, or other electric substance. The top of this tube receives the brass collar H (fig. 2. n° 3.), bored truly cylindrical, and having a small shoulder, which rests on the top of the tube. This collar is fastened with cement, and receives the hollow cylinder Φ (fig. 2. n° 2.), to which is joined the circular plate *a b*, divided on the edge into 360 degrees. It is also pierced with a round hole G in the centre, which receives the cylindrical pin *i* (fig. 2. n° 1.), having a milled head *b*, and an index *i o*, whose point is bent down, so as to mark the divisions on the circle *a b*. This pin turns stiffly in the hole G, and the cylinder Φ turns steadily in the collar H. To the lower end of the centre pin is fastened a little pincer *q*, formed like the end of a port-crayon, and tightened by the ring *q*, so as to hold fast the suspension wire, the lower end of which is grasped by a similar pincer P *o* (fig. 3.), tightened by the ring φ. The lower end φ *o* is cylindrical, and it is of such weight as to strain the wire perfectly straight, but without any risk of breaking it. It may be made half of the weight that will just break it.

This pincer is enlarged at C, and pierced with a hole, which receives tightly the arm *g* C *q* of the electrometer. This is eight inches long, and consists of a dry silk thread, or slender straw of some grass completely dried, and dipped in melted gum lac or fine sealing-wax, and held upright before a clear fire, till it form a slender cylinder of about $\frac{1}{40}$th of an inch in diameter. This occupies six of the eight inches, from *g* to *q*: the remaining two inches is a fine thread of the lac or sealing-wax, as it drains off in forming the arm. At *a* is a ball of pith of elder or fine cork, one-fourth or one-half of an inch in diameter, made very smooth, and gilded. It is balanced by a vertical circle *g* of paper, of large dimensions, stiffened with varnish. The resistance of the air to this plane soon checks the oscillations of the arm.

The whole is seen in its place in fig. 1. where the arm hangs horizontally about the middle of the height of the great cylinder. In its oscillations the ball *a* moves round in a circle, whose centre is in the axis of the whole instrument. Its situation is indicated by a graduated circle Z O Q, drawn on a slip of paper, and adhering to the glass with varnish. The electrified body, whose action is to be observed, is another small ball of cork *t*, also gilt, or a brass ball well polished. This is is carried by a ſtalk of gum lac *m e*, incloſing a dry ſilk thread. This ſtalk is graſped by a clamp of cleft deal, or any ſimilar contrivance which lies firm on the glaſs cover. When this ball is let down through the hole *m*, it ſtands ſo as to touch the ball *a* on the arm when that ball is oppoſite *o* on the graduated circle.

To electriſy the ball *t*, we employ the inſulating handle, fig. 4. which is a ſlender ſtick of ſealing-wax or lac, holding a metal wire that carries a ſmall poliſhed metal ball. We touch with it ſome electrified body, ſuch as the prime conductor of a machine, the knob of a jar, &c. Introduce this electrified ball cautiouſly into the hole *m*, and touch the ball *t* with it. The ball *a* is immediately repelled, and goes to a diſtance, twiſting the ſuſpenſion-wire, till the force of twiſt exerted by the wire balances the mutual repulſion of the balls *t* and *a*.

Such is the proceſs for examining the law of electric action. But when we would examine the action of different bodies in different ſtates, another apparatus is wanted. This is repreſented by the piece *cAd* (fig. 5.), conſiſting of a plug of ſealing-wax A, which fits tight into the hole *m*, and is pierced by the wire *c d*, hooked at *c*, to receive a wire connecting it occaſionally with an electrified body, and having below a poliſhed metal ball *d*.

The inſtrument is fitted for obſervation in the following manner: Turn the milled button *b* at top, till the twiſt-index *i o* is on the mark *o* of the twiſt circle. Then turn the whole in the collar H, till the ball *a* ſtands oppoſite to the mark *o* of the paper circle z OQ, and at the ſame time touches the ball *t* or *d*.

The obſervation is made thus: The ball *t* is electrified as already ſaid, and *a* is repelled, and retires from *t*, twiſting the wire, and, after a few oſcillations, ſettles at a diſtance correſponding to the repulſion. Now turn the twiſt-index, ſo as to force the ball *a* nearer to *t*. We eſtimate the force of this new repulſion by adding the motion of the twiſt-index to the angle at which the ball firſt reſted. By turning the twiſt-index ſtill more, we bring the balls ſtill nearer, and have a meaſure of another repulſion.—And thus may we obtain as many meaſures as we pleaſe.

In this way Coulomb aſcertained the relation between the repulſion and the diſtance to be the inverſe duplicate ratio of the diſtances. He diſcovered the law of diſſipation by air in contact, and the relation which this bears to the primitive repulſion, by obſerving the gradual approach of *a* to *t* as the electricity diſſipates from both, and by ſlackening the twiſt-index till the ball *a* retires to its primitive diſtance. He aſcertained the diſſipation along imperfect conductors, and the length neceſſary for inſulation, by completely inſulating the ball *t*, and obſerving the loſs by air in contact with it, and then ſliding a metal rod down the inſulating ſtalk, till the diſſipation began to exceed what took place by the air alone. He examined the proportion of redundant fluid in communicating bodies, by connecting them alternately with the piece, fig. 5.; as alſo by electrifying one ball, and obſerving its repulſive force, and then ſharing its electricity with another, and obſerving the diminution. He examined the graduation of his electrometer, by ſharing the electricity of one ball with an equal ball, which gave him the poſition that indicated one half; and, by repeating this, for one-fourth, &c. in the ſame manner as we practiſed and related in ELECTRICITY (*Suppl.*), n° 141, &c.

An example of one or two of theſe trials will give a clear conception of the concluſions deduced from theſe obſervations.

The ball *t* was introduced and electrified; *a* was repelled, and ſettled at 40°; the index was twiſted 140°, which brought *a* to 20; and the time was noted. The electricity gradually diſſipated, and *a* came nearer to *t*. The index was untwiſted 30°, and *a* retired a little beyond 20°; but on waiting a few ſeconds, it ſtood exactly at 20°. The time was again noted. The interval was exactly three minutes. The concluſion from the experiment was as follows:

When the ball was brought to 20°, the repulſion was evidently 140 + 20, or 160. Three minutes afterwards it was 110, + 20, or 130; and 30° were loſt in three minutes, or 10° per minute. The mean force was 145. Therefore the mean loſs per minute was, $\frac{10}{145}$. Obſerve alſo, that the primitive force correſponding to the diſtance was 40: and the force correſponding to 20 was 160, or inverſely as 20^2 to 40^2.

But obſerve, that the diſtances were not meaſured by the angles, but by the chord of the angles. The obliquity of action muſt alſo be accounted for; and the real lever is leſs than the arm, in the proportion of radius to the coſine of $\frac{1}{2}$ the angle.

The wire uſed by Coulomb in his firſt experiments on the law of action was of ſuch ſtrength, that $\frac{1}{340}$th of a French grain, applied at the point *a*, held it faſt till the twiſt-index was turned 360°; ſo that one degree correſponded to $\frac{1}{122400}$ of a grain. A foot of this wire weighed $\frac{1}{10}$th of a grain. Experience having ſhewn that this was a ſenſibility far exceeding what was neceſſary for the meaſures that he had in view, and made the inſtrument too delicate for common uſes, he ſubſtituted much ſtronger and ſhorter wires, and recommends much ſmaller dimenſions for the whole inſtrument. We have made two of only five inches in diameter and 14 inches high; the arm *a g* being $2\frac{1}{2}$ inches, and the ſuſpenſion a ſingle fibre of ſilk, carrying 30 grains. It is far more ſenſible than Bennet's gold leaf electrometer. The ſame inſtrument, with a ſilver wire ſuſpenſion, and a thread of lac projecting from the end *g*, as an index to coincide more cloſely with the ſcale, is ſufficiently nice for all experiments of meaſurement. It is always proper to have the diameter of the cylinder double the length of the arm, that the action of the glaſs may not diſturb the poſition of the arm. It is greatly improved by having a round hole in the bottom of the inſtrument, in which the cylinder C *o* of the lower pincer may hang freely: this prevents much tedious oſcillation. For ordinary experiments, for meaſuring charges of batteries, and the like, a much leſs delicate inſtrument, with a ſuſpenſion-wire ſtrained at both ends, is abundantly delicate, and vaſtly more manageable. The wire ſhould extend as far below the arm as above it, and ſhould be graſped below, by a pincer turning by a milled head in a hole at the end of a ſlender ſpring. This enables us to adjuſt the inſtrument ſpeedily. Having placed the twiſt-index at o, turn this lower button gently till the ball *a* points exactly to o on the paper circle. Even in this coarſeſt ſtate we have found it more delicate, and much more exact, than the electrometer deſcribed in ELECTRICITY (*Suppl.*) n° 85. which was much more costly, and liable to accidents. Coulomb's electrometer has the great advantage of wasting very little electricity; whereas Henley's, or Brookes's, or de Luc's, waste it very fast when it is intense.

We improved it greatly by taking away the apparatus with the ball *t*, and substituting the piece, fig. 5. for it, after changing its construction a little. Instead of the wire *c d*, we used the smallest glass tube that we could varnish on the inside, by drawing through it a silk thread dipped in varnish. Having varnished it with lac both within and without, a brass ball *d* was fixed on its lower end, and a fine wire, with a ball at top, was put down into the tube, so as to touch the ball below. When the plug was fitted into the hole *m* once for all, the situation of the ball *d* suffered no alteration. When delicate experiments are to be made, the upper ball *c* is touched by the charger, fig. 4. which electrifies *d*. C is immediately drawn out with a glass forceps; and thus *d* is left completely insulated. When external electricity, such as the faint electricity of the atmosphere is to be examined, the wire is allowed to remain in the tube.—*N. B.* A scrupulous experimenter, who may object to the straining spring recommended above, may substitute a small weight, which will be constant in its action.

The reader will observe, that this electrometer, as hitherto managed, measures only repulsions. It is not so easy to measure attractions with it; and Mr Coulomb was obliged to take a very circuitous method, during which a great deal of electricity was dissipated. In this respect, the electrometer described in the article ELECTRICITY (*Suppl.*) has the advantage; but in every other respect, Mr Coulomb's is the finest electrometer that has yet been published, giving *absolute* measures, and this with great accuracy. The Hon. Mr Cavendish has employed the construction in his most valuable experiments on the force of gravity (*Phil. Trans.* 1798, Part II.); an experiment which Newton would have been delighted with observing.

Cuthbertson's ELECTROMETER is thus described by himself in the last number of the second volume of *Nicholson's Philosophical Journal.* GH (fig. 6.) is an oblong piece of wood, about 18 inches in length, and six in breadth, in which are fixed three glass supporters, D, E, F, mounted with brass balls, *a*, *c*, *b*. Of these supporters, E and F are exactly of the same length; but D is four inches shorter. Under the brass ball *a* is a long brass hook; the ball *c* is made of two hemispheres, the under one being fixed to the brass mounting, and the upper turned with a groove to shut upon it, so that it can be taken off at pleasure. The ball *b* has a brass tube fixed to it, about three inches long, cemented on the top of F, and the same ball has a hole at the top, of about one-half inch diameter, corresponding with the inside of the tube. AB is a straight brass wire, with a knife edged centre in the middle, placed a little below the centre of gravity, and equally balanced with a hollow brass ball at each end, the centre, or axis, resting upon a proper shaped piece of brass fixed in the inside of the ball *c*: that side of the hemisphere towards *c* is cut open to permit the end *c* A of the balance to descend till it touches the ball *a*, and the upper hemisphere C is also cut open to permit the end *c* B to ascend; *i* is a weight, weighing a certain number of grains, and made in the form of a pin with a broad head; the ball B has two holes, one at the top, and the other at the bottom; the upper hole is so wide, as to let the head of the pin pass through it, but to stop at the under one with its shank hanging freely in *b*; *k* is a common Henley's quadrant electrometer; and when in use it is screwed upon the top of *c*.

It is evident, from the construction, that if the foot stand horizontal, and the ball B be made to touch *b*, it will remain in that position without the help of the weight *i*; and if it should by any means receive a very low charge of electric fluid, the two balls *b*, B, will repel each other; B will begin to ascend, and, on account of the centre of gravity being above the centre of motion, the ascension will continue till A rest upon *a*. If the balance be set again horizontal, and the pin *i* be put into its place in B, it will cause B to rest upon *b*, with a pressure equal to that weight, so that more electric fluid must be communicated than formerly before the balls will separate; and as the weight in B is increased or diminished, a greater or less quantity of electric fluid will be required to effect a separation.

When this instrument is to be applied to a jar, or battery, one end of a wire L must be inserted into a hole in *b*, and the other end into a hole of any ball proceeding from the inside of a battery, as M. A chain, or wire, or any body through which the charge is to pass, must be hung to the hook at *m*, and carried from thence to the outside of the battery, as is represented by the line N. *k* must be screwed upon *c*, with its index towards A. The reason of this instrument being added, is to shew, by the index continuing to rise, that the charge of the battery is increasing, because the other part of the instrument does not act till the battery has received its required charge.

It is almost needless to observe that this instrument consists of three electrometers, viz. Henley's electrometer, Lane's discharging electrometer considerably improved, and Brookes's steelyard electrometer improved likewise. By this combination and these improvements, we possess all that can be required in an electrometer for batteries and large jars; for, by *k*, we see the progress of the charge; by the separation of B *b*, we have the repulsive power in weight; and by the ball A, the discharge is caused when the charge has acquired the strength proposed.

In the journal from which this abstract is taken, the reader will find some curious experiments made with batteries by means of this electrometer; but one will be sufficient to explain its use. Prepare the electrometer in the manner shewn in the figure, with the jar M annexed, which contains about 168 square inches of coating. Take out the pin in B, and observe whether the ball B will remain at rest upon *b*; if not, turn the adjusting screw at C till it just remains upon A. Put into B the pin, marked *i*, weighing 15 grains; take two inches of watch-pendulum wire, fix to each end a pair of spring tongs, as is represented at G *m*, hook one end to *m*, and the other to the wire N, communicating with the outside of the jar; let the uncoated part of the jar be made very clean and dry; and let the prime conductor of an electrical machine, or a wire proceeding from it, touch the wire L; then, if the machine be put in motion, the jar and electrometer will charge, as will be seen by the rising of the index of *k*; and when charged high enough, B will be repelled by *b*, *b*, and A will descend and discharge the jar through the wire which was confined in the tongs, and the wire will be fused and run into balls. The ingenious author, by breathing through a glass pipe into the jar, damped it a little in the inside. Then loading B with a pin of 30 grains, he obtained such a charge as fused eight inches of watch pendulum wire, disposed exactly as the two inches were disposed in the former experiment. By repeating and varying his experiments, he found that double quantities of electrical fluid, in the form of a discharge, will melt four times the length of wire of a certain diameter.

ELECTROPHORUS. See ELECTRICITY in this *Supplement*.

ELEPHAS, the ELEPHANT. See *Encyclopædia*; where the natural history of this huge and sagacious animal is detailed at considerable length. Since that article was published, we have seen the third volume of the Asiatic Researches, in which some important questions, which we were then obliged to leave in uncertainty, seem to be decided by John Corse, Esq. They relate, *1st*, To the mode in which elephants copulate; which Buffon asserts (and in proof of his assertion adduces the structure and position of the generative organ in the female) to be performed while that female remains recumbent on the back; but which Mr Corse insists, from ocular evidence, takes place after the manner in which the horse copulates with the mare. *2d*, To the method of receiving nourishment from the mother; which is not, as Buffon avers, by the trunk, but by the mouth, which sucks the dug, while the trunk of the young animal grasps it round to press out the milk. *3d*, To the period of their going with young; which Mr Corse conceives cannot be less than two years; whereas Buffon and Pennant assign only nine months for the gestation of their young. His reasons for this supposition are unanswerable, and shall be given in his own words.

"As far as I know, the exact time an elephant goes with young has not yet been ascertained; but it cannot be less than two years, as one of the elephants brought forth a young one twenty-one months and three days after she was taken. She was observed to be with young in April or May 1788, and she was only taken in January preceding; so that it is very likely she must have had connection with the male some months before she was secured, otherwise they could not have discovered that she was with young, as a fetus of less than six months cannot well be supposed to make any alteration in the size or shape of so large an animal. The young one, a male, was produced October 16, 1789, and appeared in every respect to have arrived at its full time. The gentleman to whom it belongs examined its mouth a few days after it was brought forth, and found that one of its grinders on each side had partly cut the gum."

When Mr Corse wrote his memoir, the young elephant was active and well, and beginning to eat a little grass. In Africa the Hottentots feed on the elephant; and M. Vaillant declares, that an elephant's foot, when baked in their manner, is a most delicious morsel.

ELEPHANTIASIS (see MEDICINE, n° 352. *Encycl.*) is one of the most dreadful maladies with which the human race is any where afflicted. It is not indeed common, if it be found at all, in the temperate climates of Europe; but it is frequent in the East and West Indies, where it too often baffles the skill of the ablest physicians. In the second volume of the Asiatic Researches we have the following prescription for its cure:

"Take of fine fresh white arsenic one tólá, or 105 grains; of picked black pepper six times as much: let both be well beaten at intervals for four days successively in an iron mortar, and then reduced to an impalpable powder in one of stone with a stone pestle, and thus completely levigated, a little water being mixed with them. Make pills of them as large as tares or small pulse, and keep them dry in a shady place. One of those pills must be swallowed morning and evening with some betel leaf, or in countries where betel is not at hand, with cold water: if the body be cleansed from foulness and obstructions by gentle cathartics and bleeding before the medicine is administered, the remedy will be speedier."

This prescription, we are told, is an old secret of the Hindoo physicians, which they consider as a powerful remedy against all corruptions of the blood, whether occasioned by the elephantiasis or the venerial disease, which they call the *Persian* fire, and which they apply likewise to the cure of cold and moist distempers, or palsy, distortions of the face, relaxation of the nerves, and similar diseases. As the Hindoos are an ingenious and scientific people, it might be worth some European physician's while to make trial of this ancient medicine in the West Indies, where the elephantiasis or kindred diseases prove so frequently fatal.

ELEVATION, in architecture, denotes a draught or description of the principal face or side of a building; called also its *upright* or *orthography*.

ELEUTHERA, or *Alabaster*, one of the Bahama or Lucaya islands, where above 60 families formerly settled under Dep. Gov. Holmes, and erected a small fort.—*Morse.*

ELIAS, MOUNT ST. a mountain near the shore of the N. W. coast of North-America, N. W. of Admiralty bay, and S. E. of Prince William's sound.—*ib.*

ELIZABETH CITY *Co.* in Virginia, lies between York and James rivers, having Warwick and York counties on the W. and Chesapeak bay on the E. and N. There are several small islands on its sea-coast, the chief of which are Long and Egg islands. Point Comfort is the S. eastern extremity of the co. It contains 3450 inhabitants, of whom 1876 are slaves.—*ib.*

ELIZABETH *Islands*, several small islands on the S. E. side of Buzzard's bay, extending S. westerly from the extremity of Barnstable co. in Massachusetts, and bearing N. W. from Martha's Vineyard; situated between 41. 24. and 41. 32. N. lat. and between 70. 38. and 70. 56. W. long. They are about 16 in number; the chief of which are Nashawn, Pasqui, Nashawenna, Pinequese, and Cattahunk islands. All these belong to Duke's county.—*ib.*

ELIZABETH, a short southern arm of James river in Virginia. It affords an excellent harbor, and large enough for 300 ships. The channel is from 150 to 200 fathoms wide; and at common flood tide it has 18 feet water to Norfolk, which stands near the mouth of its eastern branch. The S. branch rises in the Dismal Swamp. Craney island, at the mouth of Elizabeth, lies 5 miles S. W. of Point Comfort, at the mouth of James river.—*ib.*

ELIZABETH'S ISLAND, QUEEN, in the ſtraits of Magellan, in S. America. Here freſh water, herbs fit for ſallad, and wild fowl may be had in great plenty. The ſhores alſo abound with ſhell-fiſh.—*ib.*

ELIZABETH, a townſhip in Lancaſter co. Pennſylvania, containing about 30 houſes, and a Dutch church; 18 miles N. W. by W. of Lancaſter, and 84 W. by N. of Philadelphia.—*ib.*

ELIZABETHTOWN, a poſt town and borough, in Eſſex county, New-Jerſey; pleaſantly ſituated on a ſmall creek which empties into Arthur Kull. Its ſoil is equal to any in the ſtate. In the compact part of the town, there are about 150 houſes, two brick churches, one for Preſbyterians, very handſome, the other for Epiſcopalians, and an academy. This is one of the oldeſt towns in the ſtate, having been purchaſed of the Indians as early as 1664, and ſettled ſoon after. It lies 6 miles ſoutherly of Newark, and 15 S. W. by W. of New-York.—*ib.*

ELIZABETHTOWN, a village of Alleghany co. Pennſylvania, ſituated on the S. E. ſide of Monongahela river between Redſtone Old Fort and Pittſburg, about 18 miles from each, and 6 above the mouth of the Youghagany. Many boats are built here for the trade and emigration to Kentucky, and in the environs are ſeveral ſaw-mills. N. lat. 40. 13. W. long. 79. 22—*ib.*

ELIZABETHTOWN, a poſt town of Maryland, and capital of Waſhington co. formerly called Hagarſtown, ſeated in the fertile valley of Conegocheague. It has ſeveral ſtreets regularly laid out. The houſes are principally built of brick and ſtone, in number about 300. Epiſcopalians, Preſbyterians, and German Lutherans have each a church. The court-houſe and market-houſe are handſome buildings, and the gaol is of ſtone, and ſubſtantial. The trade with the weſtern country is conſiderable; and there are a number of mills in the neighbourhood, on Antietam creek.—*ib.*

ELIZABETHTOWN, the chief town of Tyrrel co. in Edenton diſtrict, North-Carolina, has a gaol, court-houſe, and a few dwelling-houſes. It is 40 miles from Fayetteville, and 55 from Wilmington.—*ib.*

ELIZABETHTOWN, a poſt town and the chief in Bladen co. N. Carolina, is ſituated on the N. W. branch of Cape Fear. It contains a court-houſe, gaol, and about 30 houſes; 36 miles ſouthward of Fayetteville, and 47 N. W. of Wilmington.—*ib.*

ELK, a creek in Northumberland co. Pennſylvania, which uniting with Penn's creek, falls into the Suſquehanna, 5 miles below Sunbury.—*ib.*

ELK, a navigable river of the eaſtern ſhore of Maryland, which riſes in Cheſter co. Pennſylvania, by two branches; Big and Little Elk creeks. At their confluence ſtands Elkton. The canals in contemplation from Elk river, to Delaware bay, are noticed under Delaware bay.—*ib.*

ELK, a ſhort navigable river, in the ſtate of Tenneſſee. It riſes on the N. W. ſide of Cumberland mountain, runs S. weſterly, and falls into the Tenneſſee a little above the Muſcle ſhoals; about 40 miles W. N. W. of the Creeks' Croſſing Place.—*ib.*

ELKHORN, a ſmall water of Kentucky river. The Elkhorn lands are much eſteemed, being ſituated in a bend of Kentucky river, in Fayette co. in which this ſmall river, or creek, riſes.—*ib.*

ELK, *Lake*, one of the chain of ſmall lakes which connects the lake of the Woods with lake Superior. N. lat. 48. 41. W. long. 93.—*ib.*

ELKRIDGE, a ſmall town in Ann Arundel co. Maryland, ſituated on the S. bank of Patapſco river, and on the W. ſide of Deep Run. This place is famous for the bright tobacco called *kite's foot*. It is 8 miles S. W. of Baltimore, and 19 N. W. of Annapolis. N. lat. 39. 12. 30.—*ib.*

ELKTON, a poſt town of conſiderable trade, at the head of Cheſapeak bay, in Maryland, and the capital of Cecil co. It is ſituated at the confluence of the head branches of Elk river, 13 miles from its mouth at Turkey Point, and a mile above French town. The tide flows up to the town, and it enjoys great advantages from the carrying trade, between Baltimore and Philadelphia. Upwards of 250,000 buſhels of wheat are collected here annually, for ſupplying thoſe markets, or the neighbouring mills. Elkton conſiſts of one ſtreet, in which are about 90 houſes, a court-houſe, and gaol. On the W. ſide of the town is an academy. It is 12 miles S. W. of Chriſtiana bridge, 10 N. E. of Charleſtown, 47 S. W. of Philadelphia, and 56 N. E. of Baltimore.—*ib.*

ELLINGTON, a townſhip of about 200 families, in Tolland co. Connecticut. It lies about 12 miles N. E. of Hartford city, and 6 W. of Tolland.—*ib.*

ELLIPSE, or ELLIPSIS, is one of the conic ſections, popularly called an *oval*; being called an *ellipſe* or *ellipſis* by Apollonius, the firſt and principal author on the conic ſections, becauſe in this figure the ſquares of the ordinates are *leſs* than, or *defective* of, the rectangles under the parameters and abſciſſes. See *Conic Sections*, Encycl.

ELLIPSOID, is an elliptical ſpheroid, being the ſolid generated by the revolution of an ellipſe about either axis.

ELLIPTOIDE, an infinite or indefinite ellipſis, defined by the indefinite equation $a y^{m+n} = b x^{m} \overline{.a - x}^{n}$ when *m* or *n* are greater than 1: for when they are each = 1, it denotes the common ellipſe.

There are ſeveral kinds or degrees of elliptoides, denominated from the exponent $m+n$ of the ordinate y. As the cubical elliptoide, expreſſed by $a y^{3} = b x^{2} \overline{.a - x}$; the biquadratic, or furſolid $a y^{4} = b x^{2} \overline{.a - x}^{2}$; &c.

W. of Baltimore. N. lat. 39. 10. 30. —*ib.*

ENAMELLING of Vessels for the Kitchen. In the year 1779 the Society of Emulation in Paris proposed as a prize question "To discover a composition fit for making kitchen utensils which should be free from the disadvantages attending copper, lead, tinned vessels, glazed earthen ware, &c. which should be as strong as possible, less costly than the vessels used at present, and which should be able to bear the highest degree of kitchen fire, and the most sudden changes from heat to cold."

In consequence of this proposal, Mr Sven Rinman of the Royal Academy of Stockholm, without any intention of being a candidate for the premium offered by the Society of Emulation, instituted a set of experiments on small vessels of copper and hammered iron, with the view of giving to them a coating of what may properly be called *enamel*, which should not have the defects of tinning, and which, when applied to iron, should take from it the inconveniency of rusting, and of blackening many sorts of victuals when they are dressed in it. These experiments he submitted to the academy of which he was a member; and as we think them important, we shall lay the substance of them before our readers.

The most common, and the cheapest kind of white enamel that is to be met with in the shops (which is an opaque white glass, composed of powdered quartz, of glass of lead, and of calx of tin), was tried for coating kitchen utensils; and he found that it was excellent for the purpose, as it produced a coating, which was not only clean and agreeable in its appearance, but possessed likewise all the power of resisting the action of fire and of acids that could be desired. But, as it is very difficult to apply, is very dear for common use, and is besides considered as not being capable of resisting violent blows or falls, he made various experiments with substances of less price; of which the following are certainly worthy of being related.

1. The white semi-transparent fluor spar was reduced into a fine powder, with an equal quantity of unburnt gypsum, and afterwards calcined in a strong fire with a white heat; the whole being, from time to time, carefully stirred. The vessel, which he intended to coat, having first been wetted by dipping it in water, had as much of the aforesaid powder applied to its inside, by means of a very fine silk sieve, as would adhere to it of itself, or could be made to do so by pressing it with the finger. After this vessel had been dried and gradually heated, it was exposed to a sudden and violent heat, partly in a coal-fire, kept up by a pair of bellows (the vessel being at the same time covered, so that no coals or ashes could fall into it,), and partly in an assaying furnace.

In the coal fire, and with the heat as violent as is commonly used to make copper solder run, the mixture was melted, in about the space of a minute, into an opaque white enamel, which evenly covered the surface of the copper, and fixed itself pretty firmly to the metal; it also bore hard blows without breaking, and resisted the trials made by boiling things in it, and by applying acids to it. The forementioned mixture was also reduced into a fine powder in a glass mortar, and made into a sort of thin paste with water; it was then applied to the vessel with a small brush, an operation as easy as that of applying any other wet colouring matter. He likewise tried this paste, by covering vessels with it in the same way the potters apply their common glazing for stone ware. By both the above mentioned processes he obtained a very smooth coating, particularly by the latter, which is more quickly performed. When the paste is applied, the vessel should be made a little warm, so also should the paste itself.

If the constituent parts of these two substances be considered (that is to say, that gypsum is composed of calcareous earth saturated with vitriolic (sulphuric) acid, and fluor spar of a particular acid united to siliceous earth; also, that the whole, when put into the fire without the addition of any other substance, is, of all earthy or stony mixtures, that which the most easily melts into an opaque white glass, not very brittle) and if, on the other hand, the action of acids be attended to—we shall easily conceive these substances must attach themselves strongly to copper, and that the varnish formed by them cannot afterwards be dissolved or acted upon by acids.

The greatest difficulty attending on this simple mixture is, the strong and sudden heat necessary to apply it with effect, that heat being greater than is commonly to be obtained in an assaying furnace. On that account, M. Rinman endeavoured to render it more fusible by the addition of some other substance.

Of his experiments made with this view, some failed, and others succeeded. We shall record only such as were successful, and at the same time attended with such moderate expence as not to preclude them from common use.

2. With the substances employed in his first experiment, which, with the author, we shall henceforth call n° 1. he mixed an equal quantity of what is called *fusible glass (vitrum fusibile)*, composed of six parts of lime, four of fluor spar, two of quartz reduced into a fine powder, and one-tenth of a part of manganese; the whole having been calcined, and ground with water, in the manner colours are ground, he spread it on the vessel with a brush. This mixture ran pretty well upon the copper in the coal fire; it also attached itself very strongly to it, and produced an enamel which was firm and hard, and seemed likely to bear wear; but it was of a dark grey colour, and without any brilliancy. The mixture did not melt more readily in the assaying furnace.

Two parts of n° 1. with one part of the fusible glass, and a quarter of a part of manganese, had nearly the same effect. This last mixture, indeed, was rather more easily melted, but it had a darker colour.

3. Eight parts of n° 1. with one half of a part of borax, one quarter of a part of nitre, and half a part of manganese, were melted, in the space of ten minutes, into a brown liver-coloured glass; which, in the assaying furnace, produced upon the copper vessel a black enamel, which had a dull surface. In other respects it was firm, even, and hard; but it did not sufficiently cover the vessel by a single application, nor was it capable of resisting the action of acids.

4. One part of the brown glass mentioned in the last experiment, with three parts of n° 1. became, in the assaying furnace with a red heat, almost as fluid as the last, and had an even and smooth surface; but it was of a dark

Enamelling

a dark colour, and had not any brilliancy. It was not ſenſibly acted upon by vitriolic (ſulphuric) acid.

5. Four parts of n° 1, mixed with one half of a part of litharge, were melted in a crucible, with the help of the bellows, in five minutes, ſo as to become as fluid as water. This mixture, during the fuſion, emitted a ſmell of ſulphureous acid, and formed an opaque glaſs of a ſtraw colour; which, after being ground, as uſual, and ſpread upon a copper veſſel, produced an enamel which covered the veſſel very evenly, and was without bubbles. It was likewiſe, perhaps the hardeſt of all, but could not be melted in the aſſaying furnace, requiring a ſtronger fire kept up by the bellows. It preſerved its ſtraw colour, but without any luſtre, and reſiſted the action of acids better than the common glazing of the potters.

6. Mr Rinman mixed together equal quantities of gypſum, fluor, ſpar, and what the potters call *white lead* (A), and which ſerves for the baſis of their glazing. This mixture, after being calcined, melted in five minutes, with the aſſiſtance of a pair of bellows into a very white, hard, and opaque enamel, which was very eaſily poured out of the crucible. This enamel, treated like the others, ran very freely, equally, and without bubbles, by the heat of the aſſaying furnace. It was alſo pretty hard and ſtrong, but without any luſtre, and had green and yellow ſpots, occaſioned by the acids of the gypſum and fluor ſpar, which had acted upon the copper during the fuſion of the enamel. It, however, bore melting two or three times, and then appeared of a white colour; it was but very little affected by other acids.

7. Equal parts of fluor ſpar, of gypſum, of litharge, and of pure flint glaſs, powdered and mixed together, melted in five minutes, by the help of a pair of bellows, and produced a white and hard glaſs, very like that of the laſt experiment, but rather harder. After being applied on the veſſel in the uſual manner, it formed, with the greateſt heat of an aſſaying furnace, an enamel of a yellowiſh white colour, firm and hard, but without luſtre. In order to avoid the formation of bubbles, care was taken (as ought always to be done in enamelling) to remove the veſſel from the fire as ſoon as it had acquired a brilliant appearance therein, or as ſoon as the enamel was completely melted.

8. Twelve parts of glaſs of lead or of litharge, with eight parts of flint glaſs, and two of flowers of zinc, were melted, in the ſpace of ſeven minutes, into a clear yellow glaſs, which, when uſed for enamelling, was diſpoſed to form bubbles; but, by continuing the heat for a longer time, the bubbles were diſperſed, and he obtained a pretty good enamel, of a yellow brown colour with a greeniſh caſt, very hard and firm. It reſiſted the action of the vegetable acids, like the enamels already ſpoken of, but it was a little attacked by the mineral acids.

9. He powdered and mixed together five parts of fluor ſpar, five parts of gypſum, two parts of minium, one half of a part of borax, two parts of flint glaſs, one half of a part of calx of tin, and only one twenty-fifth of a part of calx of cobalt. This mixture was melted in a crucible in ſix minutes, by help of the bellows, and produced an opaque glaſs of a pearl colour, a little inclining to blue, on account of the calx of cobalt. It was pretty hard, and, after being ground with water in the uſual way, it became of a very good conſiſtence, ſo as to be very fit for ſpreading over veſſels, to which it adhered very ſtrongly. If any bubbles formed on the veſſel during its drying, they might be rubbed down with the finger, and the whole ſurface rendered ſmooth and even. After being warmed, and gradually heated, it was put into an aſſaying furnace, made very hot with birch charcoal, which had been juſt kindled under the muffle. After a minute it melted, and began to appear brilliant; ſo that he found it neceſſary to take out the veſſel very quickly, which was already very evenly coated with a thick, and ſufficiently hard, enamel, the ſurface of which, however, had no brilliancy.

Enamelling

The colour remained always inclining to green, becauſe the copper had been a little attacked by the acids of the gypſum and fluor ſpar during the fuſion; but in other reſpects this enamel was very firm, was very little hurt by ſlight blows, and bore very well ſudden changes of heat and cold. Weak acids had no action upon it; but he had ſome reaſon to think that it would, in length of time, have been acted upon, to a certain degree, by vitriolic (ſulphuric) acid. Its colour, except the forementioned ſhade of green, was white, with a dull, and rather changeable, ſurface.

The calx of cobalt, which has been juſt mentioned, and which Mr Rinman made uſe of merely with the intention of obtaining a fine colour, was prepared by ſaturating a ſolution of cobalt in aquafortis (nitric acid) with common ſalt, and evaporating to dryneſs; by which means he obtained a fine roſe-coloured calx. A very ſmall quantity of this calx, when mixed with any fuſible glaſs, gives it a beautiful blue colour.

Of the various ſpecies of enamel, which have been deſcribed in the courſe of theſe experiments, and which may be all applied, with more or leſs advantage, to kitchen utenſils, the leaſt expenſive are n^os 1, 2, and 5.; but they are alſo thoſe which require the greateſt heat. On the other hand, n° 9 may be recommended as the moſt eaſy of fuſion, and, at the ſame time, very durable when uſed for coating veſſels in which victuals are to be dreſſed, which is here the principal object, and is of far greater importance than the brilliant appearance reſulting from the enamel generally uſed by artiſts, which however may be employed when the ſaving of expence is not regarded.

The enamels hitherto deſcribed are not applicable to veſſels made of iron, though they may be employed to cover copper with great advantage. Iron will not indeed bear the common practice of enamellers, namely, to be put into the fire and taken out again ſeveral times; for the ſparks which fly from iron, when in a hot fire, detach and carry off the enamel from the parts contiguous to thoſe where the ſparks are formed. The acids, too, of the gypſum and fluor ſpar, made uſe of in the enamels already mentioned, acted upon the iron during the fuſion of the enamel, from which reſulted bubbles and bare ſpots, which entirely ſpoiled the appearance of the work. Our author therefore continued his experiments with a view to diſcover a proper enamel for veſſels made of this metal.

10. He reduced into a very fine powder, and ground together

(A) This ſubſtance is itſelf a mixture, being compoſed of four parts of lead and one of tin.

together, nine parts of minium (red oxyd of lead), six parts of flint glass, two parts of pure potash, two parts of purified nitre, and one part of borax. This mixture was put into a large crucible, which it only half filled; he covered the crucible so that no coals could fall into it, and gradually increased the fire under it. When the effervescence had entirely ceased, he caused the mixture to melt, by using the bellows for four or five minutes; by these means he obtained a clear and compact glass, which he poured out of the crucible upon a piece of marble. Having quenched it in water, and reduced it to a very fine powder in a glass mortar, he ground it with water to the consistence of a very thin paste. He then covered an iron vessel with it on both sides, which, after having dried and heated it by degrees, he put under a muffle well heated in an assaying furnace. The enamel melted very readily in the space of half a minute, and with a very brilliant appearance. He immediately withdrew the vessel, and let it cool. It was found to be entirely coated with a beautiful enamel of a black colour; which colour appeared to be caused by a thin layer of calcined iron, which might be seen through the transparency of the enamel.

A copper vessel, having been covered with the same enamel, the fine colour of the copper was visible through the thin coat of glass; and it was as well defended from rust by this coating as it would have been by an enamel of a stronger kind.

11. To hinder the colour of the metal from being seen through the coating, he added to the mixture, used in the preceding experiment, only one hundredth part of the calx of cobalt described in n° 9. The whole was melted into a beautiful blue glass; it was prepared for enamelling, and applied, in the manner before described, upon another iron vessel. The enamel proved to be smooth, thick and brilliant, like the preceding, but it covered the vessel more perfectly; it was of a fine blue colour, with some black spots in those parts where it had been most thinly applied.

12. The glass of n° 10. reduced into powder, and ground with potters white lead, of which mention has already been made, melted with the same facility; it produced a very smooth enamel, of a grey colour, but more firm and hard than the former, and, on account of the addition made to it, of a still less price. By mixing with the same glass a small quantity of crocus martis, he obtained a very fine enamel, of a dark red colour, not to mention other colours in it still more beautiful. The crocus martis he used in this experiment was prepared from a solution of iron in aqua regia (nitro-muriatic acid), which was evaporated to dryness, and the matter thus edulcorated and calcined.

13. In order to render the forementioned enamel more solid, and to give it what is called *body*, he melted together a mixture of twelve parts of flint glass, eighteen parts of minium, four parts of potash, four parts of nitre, two parts of borax, three parts of calx of tin, and one eighth part of calx of cobalt, observing always the usual precautions. He obtained a glass of a light blue colour, which, after having been ground with water, and spread upon small iron basins, or tea cups, produced, by means of a brisk fire in an assaying furnace, an enamel which was smooth and even, and of a pearl colour. The coating was of a proper thickness, to obtain which requires a certain degree of dexterity and practice. He also tried to paint upon this enamel with what is called *mineral purple (purpura mineralis)*, which he used with a little powdered quartz, nitre, and borax. It produced a very beautiful red colour.

Though this last mentioned composition is more beautiful when applied upon iron, and more even than the preceding, it has the disadvantage, on account of the salts which it contains, of not resisting the action of the stronger vegetable acids, and still less that of the mineral ones. But as a vessel when coated with this enamel bears, without any injury, sudden changes of heat and cold, and also to have any greasy mixtures baked or boiled in it, (even those which are of a caustic alkaline nature, or those which contain the usual weak acids which are used in the preparation of our food), it may be applied to vessels of various kinds, among others to tea cups; particularly as it is neither brittle nor subject to crack, provided it is not exposed to violent blows. It is hardly necessary to say, that this enamel can only be applied upon vessels made of hammered iron, and not upon those of cast iron, these last being always too thick to be heated with sufficient quickness: for the greater is the space of time necessary to make the vessels red hot, the greater is the quantity of scales formed upon them, and, of course, the enamel becomes more injured.

Our author makes some other judicious observations on the enamel for iron, of which he has described the composition, and says, that, independent of its use for coating kitchen utensils, it might be made to serve many other purposes, such as preserving things made of that metal, not only from rust, but also, as he proved by experiment, to a certain degree, from calcination.

ENCAUSTIC Painting. See Painting in this *Supplement*.

ENDEAVOUR *Straits*, are between the N. point of New-Holland, and the S. coast of New-Guinea. S. lat. 10. E. long. from Paris 140.—*Morse*.

ENFIELD (William, L. L. D.), well known in the learned world by several useful and elegant publications, was born at Sudbury, on March 29, O. S. 1741, of parents in a humble walk of life, but of very respectable characters. His amiable disposition and promising talents early recommended him to the Rev. Mr Hextall, the dissenting minister of that place, who took great care of his education, and infused into his young mind that taste for elegance in composition which ever afterwards distinguished him.

In his 17th year he was sent to the academy at Daventry, then under the direction of the Rev. Dr Ashworth, where he passed through the usual course of instruction preparatory to the office of the ministry; and with such success did he cultivate the talents of a preacher, and of an amiable man in society, that, on leaving the academy, he was at once chosen, in 1763, minister of the very respectable congregation of Benn's Garden in Liverpool.

In that agreeable town he passed seven of the happiest years of his life, very generally beloved and esteemed. He married, in 1767, the daughter of Mr Holland draper in Liverpool, with whom he passed all the rest of his days in most cordial union. His literary reputation was extended, during his residence in this place, by the publication of two volumes of sermons, which were very well received, and have ſerved to grace many pulpits beſides that in which they were originally preached. A collection of hymns and of family prayers, which he alſo publiſhed at Liverpool, did credit to his taſte and judgment.

About 1770, he was invited to take a ſhare in the conduct of the academy at Warrington, and alſo to occupy the place of miniſter to the diſſenting congregation there, both vacant by the death of the Rev. Mr Seddon. His acceptance of this honourable invitation was a ſource of a variety of mixed ſenſations and events to him, of which anxiety and vexation compoſed too large a ſhare for his happineſs. No aſſiduity on his part was wanting in the performance of his various duties; but the diſeaſes of the inſtitution were radical and incurable; and perhaps his gentleneſs of temper was ill adapted to contend with the difficulties, in matter of diſcipline, which ſeem entailed on all diſſenting academies, and which, in that ſituation, fell upon him, as the domeſtic reſident, with peculiar weight. He always, however, poſſeſſed the reſpect and affection of the beſt diſpoſed of the ſtudents; and there was no reaſon to ſuppoſe that any other perſon, in his place, could have prevented that diſſolution which the academy underwent in 1783.

During the period of his engagement there, his indefatigable induſtry was exerted in the compoſition of a number of works, moſtly, indeed, of the claſs of uſeful compilations, but containing valuable diſplays of his powers of thinking and writing. The moſt conſiderable was his "Inſtitutes of Natural Philoſophy" (quarto, Johnſon, 1783;) a clear and well-arranged compendium of the leading principles, theoretical and experimental, of the ſciences compriſed under that head. And it may be mentioned, as an extraordinary proof of his diligence and power of comprehenſion, that, on a vacancy in the mathematical department of the academy, which the ſtate of the inſtitution rendered it impoſſible to ſupply by a new tutor, he prepared himſelf, at a ſhort warning, to fill it up; and did fill it with credit and utility, though this abſtruſe branch of ſcience had never before been a particular object of his ſtudy. He continued at Warrington two years after the academy had broken up, taking a few private pupils.

In 1785, receiving an invitation from the principal diſſenting congregation at Norwich, he accepted it, and firſt fixed his reſidence at Thorpe, a pleaſing village near the city, where he purſued his plan of taking a limited number of pupils to board in his houſe. He afterwards removed to Norwich itſelf; and, at length, fatigued with the long cares of education, entirely ceaſed to receive boarders, and only gave private inſtructions to two or three ſelect pupils a few hours in the morning. This too he at laſt diſcontinued, and devoted himſelf ſolely to the duties of his congregation, and the retired and independent occupations of literature. Yet, in a private way and ſmall circle, few men had been more ſucceſsful in education, of which many ſtriking examples might be mentioned, and none more ſo than the members of his own family. Never, indeed, was a father more deſervedly happy in his children; but the eldeſt, whom he had trained with uncommon care, and who had already, when juſt of age, advanced in his profeſſional career ſo far as to be choſen town-clerk of Nottingham, was moſt unfortunately ſnatched away by a fever a few years ſince.

This fatal event produced effects on the doctor's health which alarmed his friends. The ſymptoms were thoſe of *angina pectoris*, and they continued till the uſual ſerenity of his mind was reſtored by time and employment. Some of the laſt years of his life were the moſt comfortable: employed only in occupations which were agreeable to him, and which left him maſter of his own time; witneſſing the happy ſettlement of two of his daughters; contracted in his living within the domeſtic privacy which he loved; and connected with ſome of the moſt agreeable literary companions, and with a ſet of the moſt cordial and kind-hearted friends that perhaps this iſland affords, he ſeemed fully to enjoy life as it flowed, and indulged himſelf in pleaſing proſpects for futurity. Alas! an unſuſpected and incurable diſeaſe was preparing a ſad and ſudden change: a ſchirrous contraction of the rectum, the ſymptoms of which were miſtaken by himſelf for a common laxity of the bowels, brought on a total ſtoppage, which, after a week's ſtruggle, ended in death. Its gradual approach gave him an opportunity to diſplay all the tenderneſs, and more than the uſual firmneſs, of his nature. He died November 3, 1797, amidſt the kind offices of mourning friends, and his laſt hours were peace!

Beſides the literary performances already mentioned, Dr Enfield completed, in 1791, the laborious taſk of an abridgment of "Brucker's Hiſtory of Philoſophy," which he compriſed in two volumes quarto. It may be truly ſaid, that the tenets of philoſophy and the lives of its profeſſors were never before diſplayed in ſo pleaſing a form, and with ſuch clearneſs and elegance of language. Indeed it was his peculiar excellence to arrange and expreſs other mens ideas to the utmoſt advantage. Perhaps, at the time of his deceaſe, there was not in England a more perfect maſter of what is called the middle ſtyle in writing, combining the qualities of eaſe, elegance, perſpicuity, and correctneſs, entirely free from affectation and ſingularity, and fitted for any ſubject. If his caſt of thought was not original, yet it was free, enlarged, and manly. What he was in the capacity of a teacher of religion, his ſeveral congregations will teſtify with grateful and affectionate rememberance. Few miniſters have paid ſuch unremitting attention to the perfection of their pulpit compoſitions; nor was it only by detached diſcourſes that he inculcated the truths of morality and religion, but by methodical plans of inſtruction, drawn up with great care and comprehenſion. The valuable ſtores of this kind which he left behind him, will not be conſigned to oblivion; but, it is hoped, will inform and improve numbers to whom the voice of the preacher could never have extended. In delivery, his manner was grave and impreſſive, depending rather on the weight of juſt enunciation than on the arts of oratory. Little need be added to this ſketch of the moral qualities of the excellent man above commemorated. If moderation, compliancy, and gentleneſs were ever prevalent in him to a degree of exceſs, who that knew him will blame an exceſs which opened his ſoul to every emotion and office of affection and friendſhip?

This account of Dr Enfield, which is taken from the *Monthly Magazine*, is acknowledged by its author to be the effuſion of friendſhip; but we believe that the panegyric, though high, is in general just. It is our duty, however, to warn our readers against placing implicit confidence in the Doctor's representation of ancient philosophy; for though we have frequently found him correct, and have therefore quoted him with approbation ourselves, we have likewise found him sometimes mistaking the sense of his authors. In a work like his, mistakes were indeed unavoidable; for when he resolved to compress the substance of Brucker's five volumes within the compass of two, he could not avoid sometimes giving what he thought the *sense* of the ancients, when accuracy required their very *words* to be given. This we believe to be the source of those errors in his elegant history, which we have heard others unjustly attribute to design; for had it been his *design* to deceive, he would not surely have stored his margin with references to enable every reader to detect the deceit.

Enfield, a township in Hartford co. Connecticut, on the E. bank of Connecticut river, opposite to Suffield, and bounded on the N. by the Massachusetts line: it was granted by the court of Massachusetts, to Springfield, in 1648, and was settled in 1681. In 1769 it contained 214 English families. In the town are two Congregational churches, and a meeting-house for Shakers. The compact part of the town, contiguous to the river, is very pleasant. It is 16 or 18 miles N. of Hartford.—*Morse.*

Enfield, a township in Grafton co. New-Hampshire, about 11 miles S. E. of Dartmouth College. It was incorporated in 1761, and has 724 inhabitants, chiefly farmers.—*ib.*

ENGANNO, Trompeur, or *False Cape*, is the easternmost land of the island of St. Domingo, 5½ leagues northerly of Pointe de l'Epee, and 22 S. E. of Cape Raphael, or Round Mountain. N. lat. 19. 3. W. long. from Paris 71. 25—*ib.*

ENGINEER is the appellation of him whose profession it is to contrive or make any kind of useful engine or machine. ENGONASIS, in astronomy, the same as Hercules, one of the northern constellations.

ENGRAFTING. See Grafting, *Encycl.* where it is said that there is little hope of producing mixed fruits by engrafting one tree upon another of the same class. We confess ourselves to be unwilling to relinquish this opinion; but it would be very unfair to withhold from the public any fact which seems to militate against it, and has come to our knowledge. We shall therefore transcribe from the *Philosophical Magazine* the following communication from Dr Thornton, lecturer on medical botany at Guy's Hospital, respecting a supposed *Lusus naturæ*, which he considers as the consequence of engrafting.

In the first volume of the *Philosophical Transactions*, No XXIX. published November 1667, you have the following communication, intitled,

"Some Hortulan Experiments about the engrafting of Oranges and Lemons or Citrons, whereby is produced an individual Fruit, half Orange and half Lemon, growing together as one Body upon the same Tree."

We have here orange trees (saith the intelligence from Florence) that bear a fruit which is citron on one side and orange on the other. They have been brought hither out of other countries, and they are now much propagated by engrafting. This was confirmed to us (says the editor of the Transactions of the royal Society) by a very ingenious English gentleman, who asserted, that himself not only had seen, but bought of them, anno 1660, in Paris, whither they had been sent by Genoa merchants; and that on some trees he had found an orange on one branch and a lemon on another branch (which is not so remarkable as what follows); as also, one of the same fruit, half orange and half lemon; and sometimes three quarters of one, and a quarter of the other.

In the third part of the Reports of the Board of Agriculture, among the foreign communications, we see, with equal pleasure and astonishment, an account of the American apple, which, by a peculiar mode of budding (A), is half sweet an half sour, half white and half red, without the least confusion of the respective halves.

At Mr Mason's, florist, Fleet-street, opposite the Bolt and Tun, there is a production now, September 1798, to be seen half peach and half nectarine. It has all the softness and yellow down of the peach, and the sleek red smoothness of the nectarine; supposed to be a *lusus naturæ*, but probably is rather the sportings of art than of nature, and which perhaps will be the cause why we shall in future see many other such vegetable wonders, which, as we see, were known to our ancestors.

ENNEADECATERIS, in chronology, a cycle or period of 19 solar years, being the same as the golden number and lunar cycle, or cycle of the moon.

ENO, a river in N. Carolina, which unites with Little and Flat rivers in Orange co. and forms the Neus, about 17 miles below Hillsborough.—*Morse.*

ENOREE, a N. W. branch of Broad river in S. Carolina. It separates Pinckney and Ninety-Six districts, and joins Broad river about 5 miles below Tyger river.—*ib.*

ENSETE. See Musa, *Encycl.*

EOLIPILE. See Æolipile, *Encycl.*

EPAULE,

(A) The manner in which the extraordinary nectarine peach first produced in this country was effected, was by inserting the bud of one fruit upon the stock bearing a different sort.

EPAULE, or Espaule, in fortification, the ſhoulder of the baſtion, or the angle made by the face and flank, otherwiſe called the angle of the epaule.

EPHRATA, or *Dunkard Town*, a village in Lancaſter co. Pennſylvania, ſituated on the N. W. ſide of Calico creek, which, joining the Coneſtoga, falls into the Suſquehanna. It lies 12 miles N. of the town of Lancaſter, and upwards of 60 W. of Philadelphia. It is ſituated in a romantic and ſequeſtered vale, and poſſeſſed by a religious community called *Tunkers*, who are moſtly of German deſcent, and believe in general redemption. They uſe great plainneſs of dreſs and language, and will neither ſwear, nor fight, nor go to law, nor take intereſt for the money they lend. They have many peculiarities; but their innocent manners have acquired them the name of the harmleſs Tunkers. This ſettlement is ſometimes called Tunker's Town, and conſiſts of about 40 buildings; of which 3 are places of worſhip. They ſubſiſt by cultivating their lands, by attending a printing-office, a griſt-mill, a paper-mill, an oil-mill, &c. and the ſiſters by ſpinning, weaving, ſewing, &c. Beſides this congregation at Ephrata, there were in 1770, 14 others of this ſect in various parts of Pennſylvania, and ſome in Maryland. The whole, excluſive of thoſe in Maryland, amounted to upwards of 2000 ſouls.—*Morſe*.

EPISCOPACY is a ſubject of which, in our own opinion, enough has been ſaid in the *Encyclopædia*. We are requeſted however to inſert in this place an argument additional to n° 17. of that article; and we comply with the requeſt the more readily that we find the argument, which has been ſuggeſted to us, in that very work of Dr Berkeley's which we were permitted to abridge even before our amiable friend had publiſhed it himſelf. The argument indeed is not new. It was, we believe, *firſt* uſed by Dr Wells in ſome controverſial letters againſt the Engliſh diſſenters, which were publiſhed early in the current century. Dr Berkeley adopted it from Dr Wells; and other doctors have taken it from Dr Berkeley. It is as follows:

That the apoſtles eſtabliſhed *two* orders of miniſters in the Chriſtian church is admitted by all who contend not for the equal and common rights of Chriſtians; and that the perſons occupying the higher order, by whatever title they were known, or however limited may have been the juriſdiction of each, poſſeſſed authority as well to ordain others as to preach the goſpel and adminiſter the ſacraments, is the very point on which the advocates for the divine right of preſbytery inſiſt. At the reformation, however, and for 1400 years before, there was an intermediate order of miniſters between theſe two, known by the name of prieſts or preſbyters, *authoriſed* indeed to preach the goſpel and to adminiſter its ſacraments, but *not* authoriſed to ſend labourers of any kind into Chriſt's vineyard. This *intermediate* order therefore being, by the ſuppoſition, diſtinct from the two *apoſtolical* orders of miniſters, muſt have been, at whatever period it was introduced into the church, an order of *human* invention; but it is from this order of miniſters that the clergy of thoſe churches, which are not Epiſcopal, derive all their authority to miniſter in holy things. The conſequence is obvious.

Scotch Episcopalians are a ſociety of Chriſtians certainly as reſpectable, if not ſo numerous, as any other in the kingdom which diſſents from the worſhip and diſcipline of the eſtabliſhed church. For many years, however, the public worſhip of that ſociety was proſcribed by the legiſlature; and there is reaſon to ſuſpect that its real principles are not yet univerſally underſtood. If this be ſo, it ſurely becomes the editors of a work in which ſome account is given of almoſt every denomination of Chriſtians down to the novel ſect which ſtiles its members Bereans, to do juſtice to the venerable remains of what was once the eſtabliſhed church of their native country.

1
Eſtabliſhment of Epiſcopacy in Scotland.

That the reformation from popery was in Scotland tumultuous and irregular, is known to all Europe: and very few of our readers can be ignorant that there was neither order in the reformed church, nor decency in her worſhip till James VI. with much addreſs, accompliſhed the eſtabliſhment of a very moderate epiſcopacy. To this form of church government the better part of the nation was ſufficiently attached; and it continued to be the eccleſiaſtical polity, ſupported by the ſtate, till the grand rebellion, when it was overthrown by the partizans of the *national covenant*. It was reſtored, however in 1662; and again aboliſhed in 1689 by that convention which placed the Prince and Princeſs of Orange on the ancient throne of the Scottiſh monarchs.

2
No liturgy uſed in the Scotch church,

Theſe events are ſo univerſally known, that it is ſufficient in this place barely to mention them; but there are probably many of our readers who do not know, that, during the whole period of her legal eſtabliſhment, the Scotch epiſcopal church had no public liturgy. It appears indeed, that the firſt reformers made uſe of the Engliſh book of common prayer; and there is on record ſufficient evidence that John Knox himſelf, though he diſapproved of ſome things in that book, had no objection either to ſtated forms of prayer in general, or to a ſubordination among the miniſters of the goſpel; but his ſucceſſor Andrew Melvil, who poſſeſſed neither his learning nor his worth, had influence enough to introduce into the church a perfect parity of miniſters, and to excite among the people a very general abhorrence of liturgical worſhip. So rooted indeed was that abhorrence, that, as every one knows, an attempt to introduce into the church of Scotland a book of common prayer, copied with ſome alterations from that of England, produced the *ſolemn league and covenant*, which involved in one common ruin the unfortunate Charles and his darling Epiſcopacy. At the reſtoration of the monarchy, the Epiſcopal conſtitution of the church was reſtored, but no new attempt was made to eſtabliſh the uſe of a public liturgy, and except at the ordinations of the clergy, when the Engliſh forms were uſed, no ſervice book was ſeen in a Scottiſh church.

3
Except at ordinations.

For ſome years after Epiſcopacy had ceaſed to be the religion of the ſtate, the deprived clergy made no alteration in their modes of ſocial worſhip. Having refuſed to transfer to King William that allegiance which they had ſworn to King James, they were treated, during his reign with ſuch ſeverity, that on the Lord's day they durſt not venture further than to officiate "in their own hired houſes, where they received ſuch friends as choſe to come in unto them;" and in thoſe ſmall congregations, if congregations they may be called, they continued to pray, if not extempore, at leaſt without book, till the acceſſion of Anne to the throne of her anceſtors. The attachment of that Princeſs, not only to the conſtitution, but alſo to the worſhip of the church of England, was well known to them; and they very reasonably thought that they could not more effectually recommend themselves to her protection than by adopting the use of the English liturgy, which the most enlightened among them had long professed to admire. It was accordingly introduced by degrees into Scotland; and an act of parliament being passed on the 3d of March 1712, "to prevent the disturbing of those of the Episcopal communion in that part of Great Britain called Scotland, in the exercise of their religious worship, and in the use of the liturgy of the church of England," that liturgy was universally adopted by the Scotch Episcopalians; and public chapels, which had hitherto been prohibited, were everywhere built, and well frequented.

4 Introduction of the English liturgy.

That those who had refused allegiance to King William and Queen Anne should scruple to pay it to a new family, clogged as it was by so many oaths, can excite no wonder; nor, is it at all wonderful, that, for their attachment to the abdicated family, the public worship of the Scotch Episcopalians was, after the insurrection of 1715 and 1716, laid under some restraints. These, however, were neither rigorously severe, nor of long duration; and by the year 1720, their congregations were as numerous as formerly, consisting, especially in the northern counties, of men of all ranks, even such as held offices of trust under the established government, who frequented the Episcopal chapels in preference to the parish churches.

Hitherto the Episcopalians had been safely conducted through all dangers and difficulties by the prudence of Dr Rose, the deprived bishop of Edinburgh; but soon after his death, which happened on the 20th of March, 1720, divisions broke out among them, which threatened to prove more fatal to their church than any persecution to which they had yet been subjected. For reasons which will be seen afterwards, it is proper to trace those divisions from their source.

5 Sources of division among the Scotch Episcopalians.

No native of Britain, who knows any thing of the history of his country, can be ignorant, that Dr Sancroft, the archbishop of Canterbury, and five other bishops, were at the Revolution deprived of their sees by an act of parliament; because, like the Scotch bishops, they could not bring themselves to transfer to King William and Queen Mary that allegiance which they had so lately sworn to King James. As those prelates were extremely popular for the vigorous opposition which they had given to some of the Popish projects of the late king, and as a number of inferior clergymen, of great eminence for piety and learning, were involved in the same fate with them; it need not excite great surprise, that a sweeping deprivation, which, in all its circumstances, was perhaps without a precedent in ecclesiastical history, produced a schism in the church of England. The deprived clergy, considering the bishops who were placed in the sees thus vacated as intruders, and all who adhered to them as schismatics, opened separate chapels under the authority of the primate and his nonjuring suffragans; and contended, that they and their adherents constituted the only orthodox and catholic branch of the church in England.

Both churches, however, made use of the same liturgy: and during the lives of the deprived prelates, there was no other apparent difference in their worship than what necessarily resulted from their paying allegiance to different sovereigns. But this uniformity was not of long duration. The bishops, who had been possessed of sees before the Revolution, were scarcely dead, when their successors, being under no civil restraint, found, in the principles which they had brought with them from the establishment, the means, not only of dividing their own little church, but likewise of sowing the seeds of dissension among their brethren in Scotland.

It has been observed elsewhere*, that in the church of England there are three opinions respecting the nature and end of the Lord's Supper, which, in opposition to each other, have been all patronised by men of great eminence for theological learning. It appears, indeed, from the first liturgy set forth by authority in the reign of King Edward VI. that the reformers of that church, from the errors of popery unanimously held the Lord's Supper to be a eucharistical sacrifice; and this opinion, which has been adopted by great numbers in every age since, seems to have been the most prevalent of the three among those clergy who were deprived of their livings at the Revolution. It is indeed countenanced by several passages in the present order for the administration of the Lord's Supper; and therefore, though there are other things in that order which cannot be easily reconciled to it, archbishop Sancroft, and his suffragans, whatever their own opinions might be, chose not to widen the breach between themselves and the establishment, by deviating in the smallest degree from the form in which they had been accustomed to celebrate that sacrament. Their successors, however, in office, were men of different dispositions. Considering themselves as totally unconnected with the state, and no longer bound by the act of uniformity, one party, at the head of which was bishop Collier, the celebrated ecclesiastical historian (A), judged it proper to make such alterations in the communion office as might render it more suitable to their own notions of the Lord's Supper, and bring it nearer, both in matter and form, to the most ancient liturgies of the Christian church.

* Supper of the Lord, *Encycl.*

Of the proposed alterations, some were perhaps proper in their circumstances; whilst others, to say the best of them, were certainly needless, if not inexpedient. They were accordingly *all* opposed by another powerful party of nonjurors; and the questions in dispute were referred, first to Dr Rose, the deprived bishop of Edinburgh, and afterwards to Dr Atterbury and Dr Potter, the bishops of Rochester and Oxford. What judgment the two English prelates gave in this controversy we know not; but that of bishop Rose did him much honour. Declining the office of umpire between the parties, he recommended mutual forbearance and occasional communion with each other, according to either form; and employed a gentleman, well versed in ecclesiastical literature, to prove that such a compliance of bishops with each other's innocent prejudices was not uncommon in the purest times.

These

(A) This very learned, though violent man, of whom the reader will find some account in the *Encyclopædia*, was, with Dr Hickes and others, consecrated by the deprived prelates, for the purpose of preserving the Episcopal succession in what they considered as the true church of England.

These disputes among the English nonjurors, and the appeal which was made to Dr Rose, drew, more closely than hitherto it had been drawn, the attention of the Scotch Episcopal clergy, not only to their own liturgy, which had been authorised by King Charles I. but likewise to the most ancient liturgies extant, as well as to what the fathers of the first three centuries have taught concerning the nature of the Lord's Supper. The consequence was, that such of them as were scholars soon discovered, that the Scotch communion office approached much nearer to the most ancient offices than the English; and a powerful party was formed for reviving the use of it in Scotland.

Had those men aimed at nothing farther, it is probable they would have met with very little opposition. Their opponents, who, in general, were less learned than they, were so strongly attached to the house of Stuart, that they would have adopted almost any thing sanctioned by the royal martyr's authority; but the advocates for the Scotch office knew not where to stop. They wished to introduce some other usages of the primitive church, such as the commemoration of the faithful departed, and the mixture of the eucharistic cup (See *Supper of the Lord*, n° 2. and 3. *Encycl.*); and their brethren, perceiving no authority from Charles I. for these things, and being accustomed to consider them as Popish practises, a violent controversy was ready to burst forth about what every enlightened mind must consider as matters of very little importance.

6 Revival of ancient usages.

That the eucharistic cup was in the primitive church mixed with a little water, is a fact incontrovertible; that the practice was harmless and decent, it is wonderful that any man should deny; but that such a mixture is *essential* to the sacrament, we cannot believe, for the reasons assigned in the article referred to; and therefore it ought surely to have been no object of contention.

That the faithful departed were commemorated in the primitive church long before the invention of purgatory, is known to every scholar; that in those days such a commemoration tended to invigorate the faith and the charity of Christians, it would, in our opinion, be very easy to prove; and that at present every Christian prays in private for his deceased friends, we have proved elsewhere by arguments, of the confutation of which we are under no apprehension (See *Greek-church* in this *Supplement*): but we see not the *necessity* of introducing such prayers into public worship at any period; and we perceive impropriety in doing it at a period when, from various circumstances, they may cause weak brethren to err. But those who pleaded for the revival of this practice in the beginning of the current century, were blinded by their very erudition (B); and those who opposed it seem not to have been acquainted with the workings of a benevolent and devout mind, or indeed to have known in what the essence of a prayer consists.

The ancient usages, however, were not the only subjects which, on the death of bishop Rose, furnished matter for controversy among the Scotch Episcopalians. That excellent prelate, together with the deprived archbishop of Glasgow, and the deprived bishop of Dunblain, had, from time to time, as they saw occasion, raised to the Episcopal dignity some of the most deserving Presbyters of the church; but it was resolved, for what reason we do not very well know, that none of the new bishops should be appointed to vacant dioceses during the life of any one prelate who had possessed a legal establishment; so that bishop Rose, who survived all his brethren, was for several years the ecclesiastical governor of the whole Episcopal church in Scotland. On his death, therefore, though there were four bishops in Scotland, and two Scotch bishops residing in London, there was not one of those prelates who could claim to himself the authority of a diocesan over any portion of the Catholick church. This they at first unanimously

(B) Paradoxical as this assertion may at first sight appear, nothing is more certain than that erudition, and even science, if *partially* cultivated, is as likely to blind as to enlighten the understanding. When a man devotes all his time, and all his attention, to *one* pursuit, he contracts such a fondness for it, as gradually to consider it as the *only* valuable pursuit, which will infallibly lead to truth, and to nothing but truth; and in this disposition of mind, he is ready to embrace the most extravagant absurdity to which it may conduct him. Of this the reader will find one very striking instance in page 628 vol. I. of this Suppl. where the celebrated Euler appears so devoted to his darling analysis, as to place implicit confidence in it, even when he himself seems sensible that it had led him to a conclusion contrary to common sense, and the nature of things. That Dr Bentley was a very eminent philologist, is universally known; that his emendatory criticisms on the Classics are often happy, no man will deny; and yet, misled by his favourite pursuits, he never pronounces more dogmatically than when the dogma which he utters is untenable. We appeal to his criticisms on Milton. Perhaps there is not a man alive who will refuse to Dr Waburton the praise of learning and ingenuity. The address with which he detects the double doctrines of the ancient philosophers, is sometimes almost astonishing; yet, misled by his own ardour in this pursuit, he discovers hidden meanings everywhere, and has found a rational system of religion in some of the ancient mysteries, where there is every reason to believe that nothing in reality was to be found but atheism and vice. Just so it is with the ardent reader of the Christian fathers. If he devote all his time to the study of their writings, he not only becomes enamoured of his employment, but acquires gradually such a veneration for the character of his masters (and venerable they undoubtedly are) as renders him afraid to question any thing which they advance, and unable to distinguish between their testimony, which is deserving of all credit, and their reasonings, which are often inconclusive. We trust it is needless to disclaim any wish to discourage, by this note, the study either of the Christian fathers, the Greek philosophers, philological criticism, or the modern analysis; we only wish to dissuade men of letters from devoting their whole time to any *one* pursuit whatever; for they may depend upon it, that such *partial* studies contract the mind. One of the most eminent mathematicians at present in England is reported to have declared his contempt of *the Paradise Lost*, because he found in it nothing *demonstrated!*

Episcopacy. nimously acknowledged; and one of them, in the name of himself and his brethren, recommended to the clergy of the diocese of Edinburgh to elect, after the primitive plan, a successor to their late venerable diocesan. The advice was followed; the election was made, and approved by the bishops: and Dr Fullarton, the bishop chosen, became bishop of Edinburgh, by the same means and the same authority as, in the primitive church, St Cyprian became bishop of Carthage, or Cornelius bishop of Rome.

The clergy in other districts, following the example of those in Edinburgh, diocesan Episcopacy was about to be revived throughout all Scotland upon principles purely ecclesiastical, when some of the bishops, whom Dr Rose had left behind him merely for preserving the Episcopal succession, conceived a new and very extraordinary constitution for the Scotch Episcopal church.

7 College of bishops. Whether they were envious of their colleagues, and offended that none of the elections had fallen upon them; whether they were so ignorant as not to know that diocesan Episcopacy had subsisted long before the conversion of the Roman empire, in absolute independence on the state; or that they were actuated, as there is reason to suspect, by some political principle which they could not with safety avow;—so it was, that they opposed diocesan Episcopacy of every kind, and proposed to govern the whole Scotch church by a college of bishops. Against this unprecedented scheme the more learned bishops opposed all their influence; and being exceedingly disagreeable to the inferior clergy, it was very soon abandoned by its authors themselves, who, after some acrimonious controversy, were glad to come to an agreement with their diocesan brethren.

8 Those divisions healed. Of this agreement, or *concordate* as it was called, the following were the principal articles: 1. "That the Scotch or English liturgy, and no other, might be indifferently used in the public service; and that the peace of the church should not be disturbed by the introduction of any of the ancient usages which had lately excited such dissensions. 2. That no man should thenceforward be consecrated a bishop of the Scotch church without the consent and approbation of the majority of the bishops. 3. That the bishops, by a majority of voices, should choose one of their number to preside in the meetings of his brethren, and to convocate such meetings when he judged them necessary: that this president should be styled *Primus Episcopus*, or more shortly *Primus*; but that he should not possess metropolitical power, or claim any kind of jurisdiction without the bounds of his own diocese or district. 4. That upon the vacancy of any diocese or district, the presbyters should neither elect, nor submit to, another bishop, without receiving a mandate by the Primus, issued with the consent of the majority of his colleagues."

This concordate was in 1731-2 subscribed by all the bishops then in Scotland, who immediately became diocesans, and thought no more of the college system. It was afterwards, with a few additions, for ascertaining more precisely the prerogatives of the Primus; for regulating the conduct of synods; for exempting bishops from the jurisdiction of other bishops, in whose districts they might chance to reside; and for preventing inferior clergymen from deserting their congregations, or removing from one district to another, without the consent of the bishops of both—thrown into the form of canons; and these canons have continued to be the code of the Scotch Episcopal church down to the present day. Episcopacy.

9 Political opinions. The members, and more especially the clergymen of this church, had always been considered as unduly attached to the family of Stuart; and though there was undoubtedly at first some ground for that suspicion, the writer of this article knows, from the most incontrovertible evidence, that it was continued too long, and carried by much too far. Jacobitism was imputed to the society as its distinguishing tenet; but the members of that society have at all times contended, that their distinguishing tenets were the apostolical institution of Episcopacy, and in the exercise of those powers which are purely spiritual, the independency of the church upon the state. In politics, indeed, they have unanimously maintained, that the only ruler of princes or *legislatures* is God, and not the people. They are, of course, no friends to the fashionable doctrine of resistance, which they believe to be not only condemned in express terms by Christ and two of his apostles, but to be also the source of that anarchical tyranny which is at present deluging Europe with blood. They consider a limited monarchy, like that of Britain, as the most perfect form of civil government which the world has ever seen; an hereditary monarchy is infinitely preferable to one that is elective; and with respect to the title of the monarch, when they take a retrospective view of the origin of all civil governments, they cannot but look upon a permanent and unquestioned establishment as an indication of the plan and determination of Providence furnishing the best right to a crown which any modern sovereign can claim.

10 Persecution. Surely these are harmless opinions; and yet the worship of those who held them was, in 1746 and 1748, laid under such restraints as were calculated to produce disaffection where it did not previously exist. Two laws were then enacted against the Scotch Episcopalians; which, under the pretence of eradicating their attachment to the house of Stuart, were so contrived as to preclude such of their clergy as were willing to pay allegiance to the reigning sovereign, and to pray for the royal family by name, from reaping the smallest benefit from their loyalty. The experiment was tried by some of them; of whom one venerable person, who was never suspected of undue attachment to the house of Stuart, is still alive; but he, and his complying brethren, had their chapels burnt, and were themselves imprisoned, as if they had been the most incorrigible Jacobites. This was a kind of persecution which, since the Reformation, has had no precedent in the annals of Britain. A priest of the church of Rome, by renouncing the errors of Popery, has at all times been qualified to hold a living in England; a dissenting minister, of whatever denomination, might at any time be admitted into orders, and rise to the highest dignities of the English church;—but while the laws of 1746 and 1748 remained in force, there was nothing in the power of a Scotch Episcopal clergyman to do from which he could reap the smallest benefit. By taking the oaths to government, he was not qualified to hold a living in England, or even to enjoy a toleration in Scotland; and his clerical character being acknowledged by the English bishops, he could not by those prelates be canonically reordained.

Upon

Upon the clergy, however, thoſe laws of uncommon rigour were not long rigorouſly executed. After a few years, the burning of chapels, and the impriſoning of miniſters, were occurrences far from frequent; but the laws to which we allude affected likewiſe the political privileges of ſuch laymen as frequented the Epiſcopal chapels; and in that part of their operation, thoſe laws were never relaxed till 1792, when they were wholly repealed, and the Epiſcopalians in Scotland tolerated like other well affected diſſenters from the national eſtabliſhment.

11 Toleration.

12 Faith of the Scotch Epiſcopal church.

While Epiſcopacy was the eſtabliſhed form of church government in Scotland, the clergy of that church ſubſcribed a confeſſion of faith ſummed up in twenty-five articles, which the reader will find in the hiſtory attributed to John Knox. It is ſufficient to obſerve in this place, that in eſſentials it differs little from the articles of moſt other reformed churches; and in every thing which does not immediately relate to *papiſtry*, it is moderate and unexceptionable; perhaps more ſo than the preſent confeſſion of either of the Britiſh churches. During the period which intervened between the Revolution and the year 1792, no ſubſcription was indeed required from Scotch Epiſcopalian clergymen to any ſummary of Chriſtian doctrine; but at their ordinations, thoſe clergy ſolemnly profeſſed their belief of all the canonical books of the Old and New Teſtaments; declared their perſuaſion that thoſe books contain ſufficiently all doctrines neceſſary to ſalvation, through faith in Jeſus Chriſt; and were obliged to read daily in their chapels the Engliſh book of Common Prayer, which contains the Apoſtles, Nicene, and Athanaſian creeds. But now thoſe clergymen are enjoined by act of parliament to ſubſcribe the 39 articles of the church of England; ſo that the principles of their faith are well known. No doubt there are differences of opinion among them about the ſenſe of ſome of thoſe articles; and it is well known that there are ſimilar differences among the Engliſh clergy themſelves: but there is every reaſon to believe, that the faith of the Scotch Epiſcopalians has, in every important point, been at all times orthodox.

13 Their worſhip.

We are aware, that they have been repreſented as unfriendly to the Engliſh ſervice; but ſuch a repreſention appears to be either a wilful falſehood, or the offspring of ignorance. The only reformed liturgy that ever had the ſanction of a civil eſtabliſhment in Scotland, is *the Book of Common Prayer, and Adminiſtration of the Sacraments, and other parts of Divine Service* authoriſed by King Charles I. In that book, the order of adminiſtration of the Lord's Supper differs in ſome particulars from the Engliſh order, and is unqueſtionably better adapted to the opinions of thoſe who conſider that holy ordinance either as an euchariſtical ſacrifice, or as a feaſt upon a ſacrifice. In the one or other of theſe lights, the Lord's Supper is viewed by a great majority of the Scotch Epiſcopalians; and of courſe the Scotch communion office is uſed in a great majority of their chapels: but it is not uſed in them all. Their biſhops, who, when in England, communicate with the eſtabliſhed church, leave the inferior clergy at liberty to uſe either the Engliſh or the Scotch form, as is moſt agreeable to themſelves and to the people among whom they miniſter; and to ſilence the clamour of ſymbolizing with the church of Rome, which was ſome years ago either ignorantly or maliciouſly raiſed againſt them, they altered the *arrangement* of the Scotch prayer of conſecration, ſo as not only to bring it nearer to the moſt primitive forms, but alſo to make it abſolutely inconſiſtent with the real preſence, as taught either by the church of Rome or by the Lutheran churches. On this ſubject, ſee Greek-Church, n° 17. in this *Supplement*.

14 Engliſh clergymen in Scotland.

Thus have we given a ſhort view of the diſtinguiſhing principles of what muſt ſurely be conſidered as a very reſpectable ſociety of Chriſtians, and the only reformed *Epiſcopal* ſociety in that part of Great Britain called Scotland. There are, indeed, chapels in Scotland diſtinct from the church of which we have been treating, where the Engliſh liturgy is read by clergymen who have received Epiſcopal ordination either in England or in Ireland; but thoſe chapels being all independent of each other, and under the inſpection of no biſhop, the perſons who frequent them ſeem to be rather Congregationaliſts than Epiſcopalians, and certainly do not conſtitute what can, with any propriety, be called an *Epiſcopal church*.

EPPING, a plantation in the diſtrict of Maine, of about 25 families, 12 miles from Narraguague.—*Morſe.*

Epping, a townſhip in Rockingham co. New-Hampſhire, taken from the N. W. part of Exeter, and incorporated in 1741. In 1790 it contained 1235, now 1740 inhabitants. It is 6 miles N. W. of Exeter, and 23 W. of Portſmouth.—*ib.*

EPSOM, a townſhip in Rockingham co. New-Hampſhire, lies E. of Pembroke, adjoining; 10 miles E. of Concord, and 45 miles N. W. of Portſmouth. It was incorporated in 1727; in 1775 it contained 387, and in 1790, 799 inhabitants.—*ib.*

EQUANT, in aſtronomy, a fanciful circle, introduced into ſcience to remove ſome of the defects of the Ptolemaic ſyſtem of the univerſe. In this artificial ſyſtem of epicycles and eccentric circles, the idea of circular and equable motion was by no means abandoned; but while each of the heavenly bodies revolved in its own orb, the centre of that orb was ſuppoſed to be carried at the ſame time round the circumference of another circle. The more obvious inequalities were thus explained with a geometrical preciſion. With all its nice combination, however, of circles, the ſyſtem was ſoon found to have defects; to remove which, the fine contrivance of the equant was introduced. Though the angular motion of a planet viewed from the earth was confeſſed to be unequal, a point could be conceived from which it would be ſeen to move with perfect uniformity. That point was made the centre of the equant, and lay at the ſame diſtance from the centre of the eccentricity on the one ſide, as the earth was removed on the other. "Nothing (ſays Dr Smith, from whom this account of the equant is taken) can more evidently ſhew, how much the repoſe and tranquillity of the imagination is the ultimate end of philoſophy, than the invention of this equalizing circle."

EQUATION of a curve. See Algebra *(Encycl.)* Part III. chap. ii.

Secular Equation, in aſtronomy. See Astronomy in this *Supplement*, n° 25—38.

EQUICURVE circle, the ſame with *Circle of Curvature*, which ſee in this Supplement.

ERGETT

ERGETT EL KRANE } Two Abyssinian shrubs of
ERGETT Y'DIMMO } the genus MIMOSA, which see, *Encycl.*

ERIE, FORT, a strong fortification in Upper Canada, situated on the N. shore of lake Erie, and on the W. bank of Niagara river, 27 miles S. by E. of Niagara Fort, and 18 above the carrying place at the Falls of Niagara. N. lat. 42. 59. W. long. 78. 20. 30. —*Morse.*

ERIE, a lake of the fourth magnitude in North-America, and through which runs the line between the United States and Upper Canada. D'Etroit river on the W. brings the waters of the great lakes with which lake Erie has a communication on the N. W. and Niagara river on the E. forms its communication with the waters of lake Ontario and the river St. Lawrence. It is situated between 41. and 43. N. lat. and between 78. 48. and 83. W. long. Its form is eliptical. Its length is about 225 miles; and its medium breadth about 40. It affords good navigation for shipping of any burden. The coast on both sides of the lake is generally favourable for the passage of batteaux and canoes. Its banks in many places have a flat sandy shore, particularly to the eastward of the peninsula called Long Point, which runs upwards of 18 miles into the lake, and being composed of sand is very convenient to haul boats out of the surf upon it, when the lake is too rough for sailing and rowing; yet in some places, chiefly on the S. side towards both ends of the lake, it would be dangerous to approach and impossible to land, by reason of the perpendicular height of the rocks. Some of these, (as at Cayahoga, which are already described) are magnificent beyond description, and must also inspire dread in the boldest breast, when viewed from the water. Lake Erie has a great variety of fine fish, such as sturgeon, eel, white fish, trout, perch, &c. Lakes Huron and Michigan afford communication with lake Erie, by vessels of 8 feet draught. There are portages into the waters of lake Erie from the Wabash, Great Miami, Muskingum, and Alleghany, from 2 to 16 miles. The portage between the Ohio and Potowmac will be about 20 miles, when the obstructions in the Monongahela and Cheat rivers are removed.—*ib.*

ERIE'S, an Indian nation, called by the French, du Chat, or Cat-nation. They were extirpated by the Iroquois about the year 1655. Were it not for the lake which still bears the name of that nation, one would not have known that they ever existed.—*ib.*

ERKOOM, an Abyssinian bird, part of a large tribe, "in which (says Mr Bruce) the greatest variety lies in his beak and horn. The horn he wears sometimes upon the beak and sometimes upon the forehead above the root of the beak." This bird is by naturalists called the *Indian crow* or *raven;* and our author, though he seems to think this classification improper, admits that he has one characteristic of the raven; he walks, and does not hop or jump in the manner that many others of that kind do; but then he at times runs with very great velocity, and, in running, very much resembles the turkey or bustard when his head is turned from you.

The colour of the eye of this bird is of a dark brown, or rather reddish, cast, but darker still as it approaches the pupil; he has very large eyelashes, both upper and lower, but especially his upper. From the point of the beak to the extremity of the tail is three feet ten inches; the breadth, from one point of the wing to the other extended, is six feet, and the length twenty-two inches; the length of the neck ten inches, and its thickness three inches and a half; the length of the beak, measuring the opening near the head straight to the point, ten inches; and from the point of the beak to the root of the horn, seven inches and three eighths. The whole length of the horn is three inches and a half. The length of the horn, from the foot to the extremity where it joins the beak, is four inches. The thickness of the beak in front of the opening is one inch and seven eighths. The thickness of the horn in front is one inch and five eighths. The horn in height, taken from the upper part of the point to the beak, two inches. The length of the thighs seven inches, and that of the legs six inches and five eighths. The thickness in profile seven lines, and in front four lines and a half. It has three toes before and one behind, but they are not very strong, nor seemingly made to tear up carcases. The length of the foot to the hinder toe is one inch six lines, the innermost is one inch seven lines, the middle two inches two lines, and the last outer one two inches one line. This bird is all of a black, or rather black mixed with soot-colour; the large feathers of the wing are ten in number, milk-white both without and within. The tip of his wings reaches very nearly to his tail; his beak and head measured together are eleven inches and a half, and his head three inches and a quarter. At his neck he has those protuberances like the Turkey-cock, which are light-blue, but turn red upon his being chafed, or in the time the hen is laying.

The erkoom, though not easily raised, flies (says our author) both strong and far. It has a rank smell, and is said in Abyssinia to feed upon dead carcases. This, however, he thinks a mistake, as he never saw it following the army, nor approaching a dead carcase; and as often as he had occasion to open this bird, he found in its stomach nothing but the green scarabeus or beetle. It builds in large thick trees, always, if it can, near churches; has a covered nest like that of a magpie, but four times as large as the eagle's. It places its nest firm upon the trunk, without endeavouring to make it high from the ground: the entry is always on the east side.

ERROL, a small town on lake Umbagog, in the N. easternmost settled part of Grafton co. New-Hampshire, incorporated in 1774.—*Morse.*

ERVINE, a township in Ontario co. New-York. Of its inhabitante 93 are qualified to be electors.—*ib.*

ESCAMBIA, one of the most considerable rivers that fall into the bay of Pensacola in West-Florida, empties itself near the head of the N. branch, about 12 or 15 miles from Pensacola, through several marshes and channels, which have a number of islands between them, that are overflowed when the water is high. A shoal near its mouth prevents vessels, drawing more than 5 or 6 feet, from entering; but there is from 2 to 4 fathoms of water afterwards. Capt. Hutchins ascended it in a boat upwards of 80 miles, and from the depth of water there, it appeared to be navigable for pettiaugers many miles further. It is uncertain where its

its source is. The course is very winding. At the mouth of the river on the W. side was the town of Cambleton, settled by French Protestants in 1766, but was afterwards abandoned.

The lands in general on each side of the river, are rich, low or swampy, admirably adapted for the culture of rice or corn. The great number of rivulets which fall into this river from the high circumjacent country, may be led over any part of the rice lands, at any season of the year. The numerous islands at the mouth of the river, some of very considerable extent, are not inferior for rice to any in America. The settlements made by Messrs. Tait and Mitchell, capt. Johnson, Mr. M'Kinnon, and some others, are very evident proofs of this assertion; who within two years of their first settlement, had nearly cleared all the expenses they had been at in making very considerable establishments; and would entirely have done it in another year, had not the Spaniards taken possession of the country.—*ib.*

ESPIRITU SANCTO, a bay on the W. coast of East Florida, in 27. 8. N. lat. It has a good harbor, 4 fathom water, and safe anchorage; but the land all about the coast is very low, and cannot be seen from a ship's deck when in 7 fathom water. Several low, sandy islands and marshes, covered with mangrove bushes, lie before the main land. Here are immense numbers of fish in the summer time, which may be caught with a sein, enough to load a ship, (if the climate would admit of curing them) even in a few days. —*ib.*

ESQUIMAUX, a large bay on the Labrador coast, into which a river of the same name empties. It lies in the N. W. part of the gulf of St Lawrence, near the mouth of the straits of Belleisle. Esquimaux islands lie across its mouth.—*ib.*

ESSEX *Co.* in Massacusetts, is bounded N. by the state of N. Hampshire; E. and S. by the ocean, and the town of Chelsea in Suffolk co.; W. by Middlesex co.; in length about 38 miles, in breadth 25; and is shaped triangularly, Chelsea being the acute point. The chief islands on its coast, belonging to it, are Cape Anne and Plumb islands. It is subdivided into 22 townships, which contain 7644 houses and 57,913 inhabitants; being the most populous, of its size, of any in the state, having about 135 souls to a square mile. The first settlement in Massachusetts Proper was made in Salem, the capital of the county, in 1628, by John Endicott, Esq. one of the original patentees, and many years governor of the colony. It was made a shire in 1643, being one of the three into which the colony was first divided. Essex co. pays about one seventh part of the state tax, elects six senators and counsellors for the government of the commonwealth, and one representative in the legislature of the United States.—*ib.*

The face of the county is pleasingly variegated with hills, vales, woods, and plains. The land is generally fruitful; but is more favourable to barley than most other parts of the state. Quarries of marble and limestone are found in this county; and the sea coast is indented with a number of good harbors. Merrimack river, intersects the N. part of Essex county; between it and the New-Hampshire line are the towns of Methuen, Haverhill, Amsbury and Salisbury. —*ib.*

ESSEX *Co.* in Virginia, is bounded E. and N. E by Rappahannock river, which divides it from Richmond. It is about 55 miles long and 12 broad, and contains 9122 inhabitants, of whom 5440 are slaves.—*ib.*

ESSEX *Co.* in New-Jersey, is in the eastern part of the state, and divided from Staten-Island by Newark bay. It is about 25 miles in length and 16 in breadth, and has three townships, viz. Newark, Elizabethtown and Acquackanack, which contain 17,785 inhabitants, of whom 1171 are slaves. The soil is very fertile, and its fruits and other productions meet with a quick sale in New-York city. Essex county has within it 7 Presbyterian churches, 3 for Episcopalians, 1 for Anabaptists, and 2 for Dutch Calvanists.—*ib.*

ESSEX *Co.* in Vermont, is the north-easternmost in the state.—*ib.*

ESSEX, a township in Chittenden co. Vermont, contains 354 inhabitants. It lies between Jericho on the S. E. and Colchester on the N. W.—*ib.*

ESTAPA, or *Estape*, a town belonging to the province of Tabasco, and audience of Mexico, in New-Spain, N. America. It is mentioned by Dampier, as situated on Tabasco river, 4 leagues beyond Villa de Mose. It is said to be a place of considerable trade; and so strong, that it repulsed capt. Hewet, when he attacked it with 200 desperate buccaneers.—*ib.*

ESTAPO, a strong town in New-Spain, inhabited by Spaniards and native Americans; situated at the mouth of the river Tlaluc. N. lat. 17. 30. W. long. 103. 5.—*ib.*

ESTHER *Town*, in Lancaster co. Pennsylvania, situated on the E. bank of Susquehanna river, a little N. of Harrisburg.—*ib.*

ETON is a place which, on account of its college, should not be omitted in a repository of arts, sciences, and literature; and as no notice is taken of it in the *Encyclopædia*, we shall deviate for once from the plan which we had laid down for this Supplement, and which is, not to admit into it descriptions of places in our own island that may be visited by the greater part of our readers with little trouble.

Though in a different county, namely, Buckinghamshire, Eton may be said to be one and the same town with Windsor, for which see *Encycl.* It is pleasantly situated on the banks of the Thames, in a delightful valley, which is of a remarkably healthy soil. Its college was founded by Henry VI. for the support of a provost and seven fellows, one of whom is vice-provost, and for the education of seventy King's scholars, as those are called, who are on the foundation. These, when properly qualified, are elected, on the first Tuesday in August, to king's college Cambridge, but they are not removed till there are vacancies in the college, and then they are called according to seniority; and after they have been three years at Cambridge, they claim a fellowship. Besides those on the foundation, there are seldom less than three hundred scholars, and often many more, who board at the masters houses, or within the bounds of the college. The school is divided into upper and lower, and each of these into three classes. To each school there is a master and four assistants or ushers. The revenue of the college is about

Eton.

£.5000 a-year. Here is a noble library, and in the great court is a fine statue of the founder, erected at the expence of a late provost Dr Godolphin dean of St Paul's. The chapel is in a good style of Gothic architecture. The schools and other parts, which are in the other style of building, are equally well, and seem like the design of Inigo Jones.

At Eton there is a singular, and we think a laudable, festival, called the *Montem*, celebrated triennially (formerly duennially) by the scholars of the school upon Whit-Tuesday. The following account of this festival, taken from the Monthly Magazine, will probably be acceptable to many of our readers.

It commences by a number of the senior boys taking post upon the bridges or other leading places of all the avenues around Windsor and Eton soon after the dawn of day. These youths so posted are chiefly the best figures, and the most active of the students; they are all attired in fancy dresses of silks, satins, &c. and some richly embroidered, principally in the habits or fashion of running footmen, with poles in their hands; they are called *salt-bearers*, and demand salt, i. e. a contribution from every passenger, and will take no denial.

When the contribution is given, which is *ad libitum*, a printed paper is delivered with their motto and the date of the year, which passes the bearer free through all other salt-bearers for that day, and is as follows, viz.

"Pro more et monte,
1799, (A)
Vivant Rex et Regina."

These youths continue thus collecting their salt at all the entrances for near seven miles round Windsor and Eton, from the dawn of day until about the close of the procession, which is generally three o'clock in the afternoon.

The procession commences about twelve o'clock at noon, and consists of the Queen's and other bands of music; several standards borne by different students; all the Etonian boys, two and two, dressed in officers uniforms; those of the king's foundation wearing blue, the others scarlet uniforms, swords, &c.

The Grand Standard-bearer.

The Captain, or Head Boy of Eton School.

The Lieutenant, or Second Boy.

His Majesty, attended by the Prince of Wales, and other male branches of the royal family on horseback, with their suite.

The Queen and Princesses in coaches, attended by their suite.

Band of music, followed by a great concourse of the Nobility and Gentry in their carriages and on horseback.

The procession commences in the great square at Eton, and proceeds through Eton to Slough, and round to Salt Hill, where the boys all pass the king and queen in review, and ascend the Montem: here an oration is delivered, and the grand standard is displayed with much grace and activity by the standard bearer, who is generally selected from among the senior boys.

There are two extraordinary salt-bearers appointed to attend the king and queen, who are always attired in fanciful habits, in manner of the other salt-bearers already described, but superbly embroidered. These salt-bearers carry each an embroidered bag, which not only receives the royal salt, but also whatever is collected by the out-stationed salt-bearers. The donation of the king and queen, or, as it is called upon this occasion, the *royal salt*, is always fifty guineas each; the Prince of Wales thirty guineas; all the other princes and princesses twenty guineas each. As soon as this ceremony is performed, the royal family return to Windsor. The boys are all sumptuously entertained at the tavern at Salt Hill; and the beautiful gardens at that place are laid out for such ladies and gentlemen as choose to take any refreshments, the different bands of music performing all the time in the gardens.

Eton ‖ Eudiometer.

About six o'clock in the evening all the boys return in the same order of procession as in the morning (with the exception only of the royal family), and, marching round the great square in Eton school, are dismissed. The captain then pays his respects to the royal family at the queen's lodge, Windsor, previous to his departure for King's College, Cambridge; to defray which expence, the produce of the montem is presented to him; and upon Whit-Tuesday, in the year 1796, it amounted to more than 1000 guineas. The day concludes by a brilliant display of beauty, rank, and fashion, a promenade on Windsor Terras, bands of music performing, &c. and the scene highly enlivened and enriched by the affable condescension of the royal family, who indiscriminately mix with the company, and parade the Terrace till nearly dark.

EVANSHAM, the capital of Wythe co. in Virginia, is situated on the E. side of Reedy creek, which falls into the Great Kanhaway, Woods or New river. It contains a court-house, gaol, and about 25 houses; 40 miles W. by S. of Christiansburg, 242 in a like direction from Bichmond, and 518. S. W. by W. of Philadelphia.—*Morse*.

SPONTANEOUS EVAPORATION. See WEATHER, n° 17, &c. *Encycl.*

EUDIOMETER, an instrument for ascertaining the purity of the atmospherical air. Many have been the contrivances of chemists for this purpose (see EUDIOMETER, *Encycl.*); but perhaps the best eudiometer is that of *Morveau* (or *Guyton*, as he now chooses to call himself), of which mention has been made in CHEMISTRY, n° 420. in this Supplement. The following short description will make the nature and use of this instrument plain to every reader.

AB, (Plate XXVIII.) represents a small glass retort with a long neck; its whole capacity being from seven to nine solid inches. It must be chosen of such a curvature that, when the neck is set upright, the bulb may form at its lower part a cavity to retain the matters introduced. The extremity of the neck of this retort is ground with emery to enter the glass tube CD, which is open at both ends, and about 12 or 15 inches in length. The retort then closes the tube in the manner of a ground stopper, and intercepts all external communication. A cylindrical glass vessel F is provided, of the form of a common jar, in which the glass tube CD may be entirely plunged beneath the level of the water. Lastly, the sulphuret of potash is prepared and broken

(A) Or whatever the year may be.

broken into pieces sufficiently small to be introduced into the retort. These are to be inclosed, dry and even hot, in a bottle for use. These constitute the whole apparatus and preparation of materials.

When it is required to examine an aeriform fluid, by separating its oxygen, two or three pieces of the sulphuret, of the size of a pea, are put into the retort. It is then filled with water, taking care to incline it so that all the air may pass out from the bulb. The orifice of the retort is then to be closed, and inverted into the pneumatic tube, in order that the gas proposed for examination may be transferred into it in the usual manner. By an easy manœuvre of alternately inclining the retort in different directions, all the water is made to flow out of the bulb in which the sulphuret remains. When this is done, the retort is placed in the vertical situation, and its extremity introduced into the tube of glass CD, which must always be under water. A small lighted taper is then to be placed under the bulb. To support the retort in its position, the jar is provided with a wooden cover, in which there is a notch to receive it.

The first impression of the heat dilates the gaseous fluid so much that it descends almost to the bottom of the tube, which is disposed expressly for its reception; otherwise the partial escape would prevent an accurate determination of its change of bulk. But as soon as the sulphuret begins to boil, the water quickly rises, not only in the inferior tube, but likewise in the neck of the retort, notwithstanding the application, and even the increase of the heat.

If the fluid be absolutely pure vital air, the absorption is total. In this case, to prevent the rupture of the vessel by too sudden refrigeration, the ascent of the water must be rendered slower, either by removing the taper, or by increasing the perpendicular height; which will not prevent the absorption from continuing while any gas remains which is proper to support combustion.

If the fluid be common air, or oxygen mixed with any other gas, the quantity of water which has entered the retort must be accurately measured after the cooling. It represents the volume of air absorbed. Care must be taken to inclose the remaining gas under the same pressure, by plunging the retort to the level of the line at which the inclosed water rests, before the orifice is stopped.

This operation of measuring, which is very easy when measuring vessels are at hand, may be habitually performed by a slip of paper pasted on the neck of the retort, upon which divisions are drawn from observation, and which must be covered with varnish to defend it from the action of the water.

EUDOXUS of Gnidus was a celebrated philosopher of the school of Pythagoras. His first preceptor was Archytas, by whom he was instructed in the principles of geometry and philosophy. About the age of twenty-three he came to Athens; and though his patrimony was small, by the generous assistance of Theomedon, a physician, he was enabled to attend the schools of the philosophers, particularly that of Plato. The liberality of his friends afterwards supported him during a visit to Egypt, where he was introduced by Agesilaus to king Nectanebis II. and by him to the Egyptian priests. It has been said that he accompanied Plato into Egypt; but this is inconsistent with chronology; for Nectanebis II. reigned in Egypt from the second year of the hundred and fourth Olympiad, to the second year of the hundred and seventh; and it was before Plato opened his school, that is, before the ninety-eighth Olympiad, about the fortieth year of his age, that he visited Egypt. Eudoxus is highly celebrated by the ancients for his skill in astronomy, but none of his writings on this or any other subject are extant. Aratus, who has described the celestial phenomena in verse, is said to have followed Eudoxus. He flourished about the ninety-seventh Olympiad, and died in the fifty-third year of his age. *Enfield's Hist. of Philosophy*.

EVECTION is used by some astronomers for the libration of the moon, being an inequality in her motion, by which, at or near the quadratures, she is not in a line drawn through the centre of the earth to the sun, as she is at the syzygies, or conjunction and opposition, but makes an angle with that line of about 2° 51′. The motion of the moon about her axis only is equable; which rotation is performed exactly in the same time as she revolves about the earth; for which reason it is that she turns always the same face towards the earth nearly, and would do so exactly, were it not that her monthly motion about the earth, in an elliptic orbit, is not equable; on which account the moon, seen from the earth, appears to librate a little upon her axis, sometimes from east to west, and sometimes from west to east; or some parts in the eastern limb of the moon go backwards and forwards a small space, and some that were conspicuous, are hid, and then appear again.

The term *evection* is used by some astronomers to denote that equation of the moon's motion which is proportional to the sine of double the distance of the moon from the sun, diminished by the moon's anomaly. This equation is not yet accurately determined: some state it at 1° 30′, others, at 1° 16′, &c. It is the greatest of all the moon's equations, except the equation of the centre. *Hutton's Dictionary*.

EVENLY EVEN NUMBER. See NUMBER, *Encycl.*

EVENLY Odd Number. See NUMBER, *Encycl.*

EVESHAM, a township in Burlington co. New-Jersey, situated between the forks of Moore's creek, which runs N. westerly to Delaware river. It is 7 miles easterly of Haddonfield, 16 E. of Philadelphia, and 25 S. of Burlington.

Here is an Indian settlement, called Edge Pelick, a tract of land reserved by the ancient natives. They have some hundreds of acres of improved lands, about 30 houses, and a meeting-house. They formerly had a minister of their own order, who statedly officiated in the Indian language.—*Morse*.

EVOLVENT, in the higher geometry, a term used by some writers for the involute or curve resulting from the evolution of a curve, in contradistinction to that evolute, or curve supposed to be opened or evolved. See EVOLUTE and INVOLUTE, *Suppl.*

EVOLUTE, in the higher geometry, a curve first proposed by Huyghens, and since much studied by mathematicians. It is any curve supposed to be evolved or opened, by having a thread wrapped close upon it, fastened at one end, and beginning to evolve or unwind the thread from the other end, keeping the part evolved or wound off tight stretched; then this end of the thread will describe another curve, called the *involute*. Or the same involute is described the contrary way, by wrapping the thread upon the evolute, keeping it always stretched. For the INVOLUTION and EVOLUTION *of Curves*, see INVOLUTION in this Supplement.

Imperfect EVOLUTE, a name given by M. Reaumur to a new kind of evolute. The mathematicians had hitherto only considered the perpendiculars let fall from the involute on the convex side of the evolute: but if other lines not perpendicular be drawn upon the same points, provided they be all drawn under the same angle, the effect will still be the same; that is, the oblique lines will all intersect in the curve, and by their intersections form the infinitely small sides of a new curve, to which they would be so many tangents. Such a curve is a kind of evolute, and has its radii; but it is an imperfect one, since the radii are not perpendicular to the first curve or involute.

EUPHON, a musical instrument invented lately by Dr Chladni of Wittenberg, well known by his various publications on philosophical subjects, especially the theory of musical sounds. The euphon consists of forty-two immoveable parallel cylinders of glass of equal length and thickness; but its construction, tone, and the method of playing it, are totally different from those of the harmonica, with which indeed it has nothing in common but the glass. See HARMONICA, *Encycl.*

Dr Chladni gives the following account of his invention. In his 19th year he began to learn to play the harpsichord; and he afterwards read a great many of the principal works on the theory of music, by which he found that the physico-mathematical part of that science was far more defective than other branches of natural philosophy. Being therefore possessed with an idea that his time could not be better emyloyed than in endeavouring to make discoveries in this department, he accordingly tried various experiments on the vibrations of strings and the different kinds of vibration in cylindric pieces of wood, first discovered, through calculation by the elder Euler; and found, that though a great deal had been said on the nature of these elastic bodies, yet the manner of vibration and the proportion of tones in other elastic bodies, which do not proceed, as in the former, in straight lines, but depend on the vibration of whole surfaces, were totally unknown, and that the little which had been written on that subject, by some authors, did not correspond with nature. He had already long remarked, that every plate of glass or metal emitted various tones according as it was held and struck in different places; and he was desirous to discover the cause of this difference, which no one had ever examined. He fixed in a vice the axle of a brass plate which belonged to a polishing machine, and found, that by drawing the bow of a violin over it, he produced very different tones, which were stronger, and of longer duration than those obtained merely by striking it.

The observation, that not only strings, but also other elastic bodies may be made to produce sounds by drawing a violin bow over them, Dr Chladni does not give as a discovery of his own; as the so called iron violin has been long known, and as he had read of an instrument constructed in Italy*, where glass or metal bells were made to sound by means of two or more violin bows drawn over them. But the idea of employing this instrument to examine vibrating tones was first entertained by himself. Having accurately remarked the tones produced by the abovementioned metal plate, he found that they gave a progression which corresponded with the squares of 2, 3, 4, &c.

* In all probability the *Harmonica* of the Abbé Mazzuchi.

Not long before he had read, in the Transactions of the Royal Society of Gottingen, the observations of Mr Lichtenberg on the phenomena produced by strewing pounded resin over a glass plate or cake of resin, and he repeated many of his experiments. This led him to the idea that, perhaps, the various vibratory movements of such a plate would be discovered by a diversity of phenomena, if he strewed over it sand or any thing of the like kind. By this experiment there was produced a star-formed figure; and the author, having continued his researches, published the result of them in a work entitled Discoveries respecting the Theory of Sound, printed at Leipsic in 1787.

Whilst he was employed in these investigations, he resolved to invent a new musical instrument; and he began to consider whether it might not be possible by rubbing glass tubes in a straight line, with the wet fingers, to produce sounds in the same manner as is done in the harmonica by rubbing them circularly. That glass tubes, like those in his euphon, would not merely by such rubbing emit any tones, he had long known by theory and experience; and he therefore applied himself to the solution of the difficult question, in what manner the instrument ought to be constructed to answer the intended purpose? After various fruitless attempts for a year and a half, during which his imagination was so full of the idea, that sometimes in his dreams he thought he saw the instrument and heard its tones, that is, like those of the harmonica, but with more distinctness and less confusion, he at length, in a state between sleeping and waking, obtained a solution of the problem which had given so much employment to his thoughts. On the second of June 1789, being tired with walking, he sat down on a chair, about nine in the evening, to enjoy a short slumber; but scarcely had he closed his eyes when the image of an instrument, such as he wished for, seemed to present itself before him, and terrified him so much that he awoke as if he had been struck by an electric shock. He immediately started up in a kind of enthusiasm; and made a series of experiments, which convinced him that what he had seen was perfectly right, and that he had it now in his power to carry his design into execution. He made his experiments and constructed his first instrument in so private a manner, that no person knew any thing of them. On the 8th of March 1790 his first instrument of this kind was completed; and in a few days he was able to play on it some easy pieces of music. It was now necessary to give to this instrument, as it was entirely new, a new name; and that of *euphon*, which signifies an instrument that has a pleasant sound, appeared to him the most proper.

It was not, however, brought to perfection at once, for he made a second instrument which was an improvement of the first, and a third which was an improvement of the second. In sound, indeed, and particularly in the higher tones, the first was equal to either of the other two; but the construction was deficient in strength, so that every week some hours were necessary to keep it in proper repair; and it was impossible to convey it the distance of a mile without almost totally destroying it. Dr Chladni also, for want of better tubes, employed those used for thermometers, and marked

Euphon. marked the whole and half tones by a coating of sealwax on the under side; but as the wax, owing to the moisture and vibration, often cracked and flew off, it was attended with danger to the eyes. It was therefore extremely difficult to give to the construction of the instrument sufficient strength; but this the inventor at length accomplished, so that his new euphon cannot be injured or put out of tune either by playing or by carriage. The third instrument was somewhat different from the first and second; as the fore part, which in the two former rose upwards with an oblique angle, stood at right angles, so that it could be transported with ease in a particular carriage made for that purpose. Instead of the thermometer tubes used in the first, the Doctor now employs tubes of different colours. In the second instrument those for the whole tones were of dark green glass; but he used for the half tones, in both, a milk white kind of glass. In a word, the euphon has some resemblance to a small writing-desk. When opened, the abovementioned glass tubes, of the thickness of the barrel of a quill and about 16 inches long, are seen in a horizontal position. They are wetted with water, by means of a sponge, and stroked with the wet fingers in the direction of their length, so that the increase of the tone depends merely on the stronger or weaker pressure, and the slower or quicker movement of the fingers. The number of tubes at present is forty-two. In the back part there is a perpendicular sounding-board divided in the middle, through which the tubes pass. It appears therefore that the euphon ought not to be considered as an altered or improved harmonica, but as a totally new and different instrument. In regard to sweetness of sound, it approaches very near to the harmonica; but it has several advantages which no unprejudiced person, who examines both instruments, will deny.

1. It is simpler, both in regard to its construction and the movement necessary to produce the sound, as neither turning nor stamping is required, but merely the movement of the finger. 2. It produces its sound speedier; so that as soon as it is touched you may have the tone as full as the instrument is capable of giving it; whereas, in the harmonica, the tones, particularly the lower ones, must be made to increase gradually. 3. It has more distinctness in quick passages, because the tones do not resound so long as in the harmonica, where the sound of one low tone is often heard when you wish only to hear the following tone. 4. The unison is purer than is generally the case in the harmonica, where it is difficult to have perfect glasses, which in every part give like tones with mathematical exactness. It is however as difficult to be tuned as the harmonica. 5. It does not affect the nerves of the performer; for a person scarcely feels a weak agitation in the fingers; whereas in the harmonica, particularly in concords of the lower notes, the agitation extends to the arms, and even through the whole body of the performer. 6. The expence of this instrument will be much less in future than that of the harmonica. 7. When one of the tubes breaks or any other part is deranged, it can be soon repaired, and at very little expence; whereas, when one of the glasses of the harmonica breaks, it requires much time, and is very difficult to procure another capable of giving the same tone as the former, and which will correspond sufficiently with the series of the rest. Euphorbia.

EUPHORBIA (See *Encycl.*). Of this plant three new species were discovered by Le Vaillant during his last travels into the interior parts of Africa. The first, which he calls the CUCUMBER-EUPHORBIA, adheres to the earth no otherwise than by a few slender roots. It rises to the height of nine or ten inches only; and exactly resembles a cucumber, of which it has the bent shape. (Plate XXVIII. fig. 1.) It contains abundance of milky juice, which appeared to him as caustic as that of the great euphorbia. Its colour, which is a yellowish green, tinted with a beautiful shade of violet towards the root, gives it a very attractive appearance: but woe betide the man who should be tempted to eat of it! as it is a virulent poison. The second, to which he gave the name of the MELONRIBBED EUPHORBIA, does not rise more than three or four inches from the ground, to which it adheres by a collection of fibrous roots, issuing from several tubercles disposed in the manner of a crown. (Fig. 2.) The stem forms a flatted globe excavated at the summit, and has ribs like the apple which in France is called *calville blanche*. These ribs are elevated, thick, and convex, have a greenish colour, and are marked with brown transversal bands. From the summit of the ribs issue several little tufts of pedunculate flowers. The third he called the CATERPILLAR-EUPHORBIA, because when he first found it, he thought he perceived on it several beautiful caterpillars. (Fig. 3.) The description of it in a few words is as follows: From a very large tuberous root, which here and there throws out a few thready fibres, issue several stalks almost of the length of the finger: they creep along the ground, are twisted, woody, destitute of leaves, and furnished with several rows of round tubercles, each guarded by two prickles.

All these kinds of euphorbia are to be dreaded, the last two in particular; because being low and mixed with the herbage like mushrooms, animals, as they feed, run the risk of eating them with their pasture. Our author confirms the account which has been given in the *Encyclopædia* of the savages poisoning the reservoirs of water with this plant in order to procure the game which shall drink of it. To effect the death of the animal, it is necessary that the poison reach the blood and mingle with it. Yet, inconceivable as it may be, the animal, though poisoned, is not the less wholesome food, as our author says he has experienced. However great may be the proportion of euphorbia thrown into a pond of water, he is persuaded that it never diffuses itself through the whole mass. It is his opinion, that the poison is a resinous juice, which, being from its nature incapable of combining with water, swims on the surface, and there forms a shining greenish oil, which with a little attention may be discerned by the naked eye when the surface is smooth. I tried (says he) the qualities of this oil on myself, taking with a straw, from the surface of the basin, a single drop, which I put upon my tongue; and it gave me that kind of burning pain which a caustic occasions. I then took up some water from the reservoir in the hollow of my hand, and blowing off the oily fluid which swam on the surface, I dipped the end of my tongue into the remainder, but could not perceive in it the slightest taste different from that of water itself. He seems to think that milk is an antidote

tidote to the poison of euphorbia; because he squeezed some of the juice into a bason of milk and gave it to an ape, which swallowed part of it without the least injury. He confesses, however, that the dose was trifling.

EUSTACE, or *Eustatia*, called also Metanzas, or Slaughter, (from a butchery made on it by the Spaniards). It is an inconsiderable island, about 20 miles in circuit. It forms, with a long point of land, the entrance to the harbor of St. Augustine, in East-Florida—*Morse*.

EUSTYLE, is the best manner of placing columns, with regard to their distance; which, according to Vitruvius, should be four modules, or two diameters and a quarter.

EXCENTRIC, or Excentric Circle, in the ancient Ptolemaic astronomy, was the very orbit of the planet itself, which it was supposed to describe about the earth, and which was conceived excentric with it; called also the deferent.

Instead of these excentric circles round the earth, the moderns make the planets describe elliptic orbits about the sun; which accounts for all the irregularities of their motions, and their various distances from the earth, &c. more justly and naturally.

Excentric, or *Excentric Circle*, in the new astronomy, is the circle described from the centre of the orbit of a planet, with half the greatest axis as a radius; or it is the circle that circumscribes the elliptic orbit of the planet.

EXCHANGE. See *Encycl.* under that word, and likewise under *Bills of Exchange*, where the antiquity of such bills, especially among the Chinese, is mentioned. In Professor Beckmann's history of inventions the reader will find an ordinance of the year 1394 concerning the acceptance of bills of exchange, and also copies of two bills of the year 1404, which sufficiently prove that the method of transacting business by bills of exchange was fully established in Europe so early as the fourteenth century; and that the present form and terms were even then used. The ordinance, which was issued by the city of Barcelona, decreed that bills of exchange should be accepted within twenty-four hours after they were presented, and that the acceptance should be written on the back of the bill.

But there are questions relating to bills of exchange of much greater importance than their antiquity; and these questions are not yet decided. For instance, Ought a bill of exchange to be considered by the law merely as a *deposit* belonging to the drawer, and successively confided to the remittees? or should it be considered as transferable *property*, at all times absolutely vested in the holder, whose neglect therefore, when it vitiates the value, falls wholly on himself?

In a work published 1798 by Professor Busch of Hamburgh, entitled, *Additions to the Theoretical and Practical Delineation of Commerce* (A), the reader will find some arguments, which, to say the least of them, are certainly plausible, to prove that bills of exchange ought to be at all times considered as the absolute property of the holder. This theory is then applied to the difficult and still unsettled case of the holder of a bill having many indorsements, where the drawer, drawee, and early indorsers, have all failed. It is evident that, if the holder proves under each bankruptcy the whole amount of the bill, he will receive much more than his due. May he make his election where to prove the whole demand, and where to prove the residue? Or ought he not (which seems most equitable) to be compelled to prove his debt against his immediate predecessor only?—the assignees of that predecessor proving, in their turn, in like manner (each party once only), back to the drawer. This is a case of great importance to discounters, and the reader will find some judicious observations on it in the Professor's work.

EXEGESIS, or Exegetica, in algebra, is the finding, either in numbers or lines, the roots of the equation of a problem, according as the problem is either numeral or geometrical.

EXETER, a post town in Rockingham co. New-Hampshire, and, next to Portsmouth, the most considerable sea-port town in the state. It is situated at the head of navigation on Swamscot, or Exeter river, a branch of the Piscataqua, 15 miles S. W. of Portsmouth, and a like distance N. W. of Newburyport, in Essex co. Massachusetts. The tide rises here 11 feet. It is well situated for a manufacturing town, and has already a duck manufactory in its infancy, 6 saw mills, a fulling mill, slitting mill, paper mill, snuff mill, 2 chocolate and 10 grist mills, iron works, and 2 printing offices. The saddlery business is carried on here to greater extent, than in any town on this side Philadelphia. Before the revolution, ship building was a profitable business; and the vessels were employed in the West India trade. Notwithstanding the loss of this market, there are four or five vessels, of different burden, built here annually; the river being capable of floating down those of 500 tons. An equal number is also employed in the foreign trade, chiefly to the West-Indies. The situation of this place bids fair for extensive population. The public edifices are 2 Congregational churches, an elegant building appropriated for the academy, a handsome and capacious court-house, and a gaol. The public offices of the state are kept here at present. Besides the celebrated Exeter academy, there are here an English school and 6 or 8 private schools, chiefly for females.

This township is of irregular figure, and about 4 miles square. It was incorporated in 1638; prior to which, it had the name of Swamscot Falls, from the falls of the river, which separate the fresh from the tide water; where the body of the town is situated; chiefly on the western side of the river. The number of inhabitants in 1775, was 1741—and in 1790, 1722. It lies 54 miles N. of Boston, and 402 N. E. of Philadelphia. N. lat. 42. 59. W. long. 71.

"Phillips Exeter Academy" was founded and endowed by the hon. John Phillips, L. L. D. of Exeter, and incorporated by act of Assembly in 1781. It is a very respectable and useful institution, under the inspection of a board of trustees, and the immediate government and instruction of a preceptor and an assistant. It has a fund of £.15,000, a part of which is in lands not yet productive. The present annual income is £.480.

(A) Professor Busch published in 1792 a work entitled *A Theoretical and Practical Delineation of Commerce.*

£.480. It has commonly between 50 and 60 students. In 1794, a building was erected, 76 by 36 feet, two stories high; which, in point of convenience, and perhaps elegance, is exceeded by few buildings of the kind in the United States.—*Morse.*

Exeter, the N. westernmost township in Washington co. Rhode-Island state, has North-Kingston on the E. and Voluntown, in Connecticut, on the W. The several branches of Wood river unite here, and take a S. course between Hopkinton and Richmond. It contains 2495 inhabitants, of whom 37 are slaves.—*ib.*

Exeter, a township in Luzern co. Pennsylvania. —*ib.*

Exeter, a town in New-Hanover co. in Wilmington district, N. Carolina; situated on the N. E. branch of Cape Fear, about 36 miles N. from Wilmington, and 22 from the New river.—*ib.*

EXPECTATION of Life, in the doctrine of life annuities, is the share, or number of years of life, which a person of a given age, may, upon an equality of chance, expect to enjoy.

By the expectation or share of life, says Mr Simpson (*Select Exercises*, p. 273), is not here to be understood that particular period which a person hath an equal chance of surviving; this last being a different and more simple consideration. The expectation of a life, to put it in the most familiar light, may be taken as the number of years at which the purchase of an annuity, granted upon it, without discount of money, ought to be valued. Which number of years will differ more or less from the period abovementioned, according to the different degrees of mortality to which the several stages of life are incident. Thus it is much more than an equal chance, according to the table of the probability of the duration of life which the same author has given us, that an infant, just come into the world, arrives not to the age of ten years; yet the expectation or share of life due to it, upon an average, is near twenty years. The reason of which wide difference is the great excess of the probability of mortality in the first tender years of life, above that respecting the more mature and stronger ages. Indeed if the numbers that die at every age were to be the same, the two quantities above specified would also be equal; but when the said numbers become continually less and less, the expectation must of consequence be the greater of the two.

EXPONENTIAL Calculus, the method of differencing, or finding the fluxions of exponential quantities, and of summing up those differences, or finding their fluents.

Exponential *Curve*, is that whose nature is defined or expressed by an exponential equation; as the curve denoted by $a^x = y$, or by $x^x = y$.

Exponential *Equation*, is one in which is contained an exponential quantity: as the equation $a^x = b$, or $x^x = ab$, &c.

Exponential *Quantity*, is that whose power is a variable quantity, as the expression a^x, or x^x. Exponential quantities are of several degrees and orders according to the number of exponents or powers, one over another.

EXTRA Constellary Stars, such as are not properly included in any constellation.

EXTRA-Mundane Space, is the infinite, empty, void space, which is by some supposed to be extended beyond the bounds of the universe, and consequently in which there is really nothing at all. The phrase *extramundane space* has been so long in use among our best writers, that it is now impossible to banish it from the language; and yet it has been the source of some extravagant mistakes. Many philosophers consider space as something *real*, distinct both from body and mind; and no less a man than Dr Clarke considered it as an attribute of the Deity. Yet we think nothing more evident than that if body had never existed, space would never have been thought of; and if this be so, extramundane space, instead of denoting any *real* thing, or attribute infinitely extended, can mean nothing more than the *possibility* of enlarging the corporeal universe, however widely extended it may be. See Metaphysics (*Encycl.*), Part II. ch. iv.

EXTRADOS, the outside of an arch of a bridge, vault, &c. See Arch in this *Supplement*.

EXTREMES Conjunct, and *Extremes Disjunct*, in spherical trigonometry are, the former the two circular parts that lie next the assumed middle part; and the latter are the two that lie remote from the middle part. These were terms applied by Lord Napier in his universal theorem for resolving all right-angled and quadrantal spherical triangles, and published in his *Logarithmorum Canonis Descriptio*, an. 1614. In this theorem, Napier condenses into one rule, in two parts, the rules for all the cases of right angled spherical triangles, which had been separately demonstrated by Pitiscus, Lansbergius, Copernicus, Regiomontanus, and others. In this theorem, neglecting the right angle, Napier calls the other five parts circular parts, which are, the two legs about the right angle, and the complements of the other three, viz. of the hypothenuse, and the two oblique angles. Then taking any three of these five parts, one of them will be in the middle between the other two, and these two are the extremes conjunct when they are immediately adjacent to that middle part, or they are the extremes disjunct when they are each separated from the middle one by another part.

EXUMA *Isle*, one of the Bahama isles, situated on the E. of the Great Bank, between Stocking isles on the S. W. and Long-isle on the E. It is now uninhabited, excepting two families, yet is one of the best of the Bahamas, not only for its fertility, but for the excellence of its anchoring ground, in the sound to which it gives name; where all the British navy could ride in safety. N. lat. 24. 30. W. long. 74. 30.—*Morse.*

Exuma *Sound*, lies E. of the Great Bahama Bank, between it and the isle of Guanahani. N. lat. 24. W. long. 75.—*ib.*

FABIANE,

F.

FABIANE, a river in Louisiana, which runs S. eastward into the Missisippi, in N. lat. 39. 30.; 16 miles above Jastioni river and 50 below the Iowa town and rapids.—*Morse.*

FABIUS, one of the military townships in New-York.—*ib.*

FACE or FAÇADE, in architecture, is sometimes used for the front or outward part of a building, which immediately presents itself to the eye; or the side where the chief entrance is, or next the street, &c.—*ib.*

FAIRFAX *Co.* in Virginia, is about 25 miles long, and 18 broad; on the W. Bank of Potowmack river. It contains 12,320 inhabitants, of whom 4574 are slaves. Chief town, Alexandria.—*ib.*

FAIRFAX, a township in Franklin co. Vermont, E. of Georgia, and on the bank of La Moille river, and contains 254 inhabitants; and is about 9 miles from lake Champlain.—*ib.*

FAIRFIELD, a plantation in Lincoln co. district of Maine, on the S. E. bank of Kennebeck river, S. of Canaan, and opposite Hancock; about 17 miles from Pittstown, and 7 from Fort Halifax. It contains 492 inhabitants, and is 225 miles N. E. of Boston.—*ib.*

FAIRFIELD, a new township in Herkemer county, New-York.—*ib.*

FAIRFIELD, a township in Franklin co. Vermont, E. of St. Albans; and contains 129 inhabitants. It is 13 miles S. of the Canada line, and as far from the nearest part of lake Champlain.—*ib.*

FAIRFIELD, a township in Washington co. New-York. By the state census of 1796, 29 of its inhabitants are electors.—*ib.*

FAIRFIELD, a township in Cumberland co. New-Jersey, on Cohanzy creek, and at the head of Black creek; 25 miles E. by S. of Salem, in Salem co.—*ib.*

FAIRFIELD *Co.* in Connecticut, is the S. westernmost in the state; bounded W. by the state of New-York, E. by New-Haven co. N. by Litchfield, and S. by Long-Island sound. Its shape is very irregular. It is divided into 13 townships, of which Fairfield and Danbury are the chief; and contains 36,250 inhabitants, including 433 slaves. It is separated from New-Haven co. and part of Litchfield co. by Stratford river. The other parts of the county are watered by small streams, as Sagatnck, Safco, Peganook, Five Mile, Rodens, Mill, and Mayamus rivers. Several harbors, and a number of small isles lie along the sound, in the towns of Greenwich, Stamford, Norwalk, Fairfield, and Stratford. The face of the county is rough, but the soil is good.—*ib.*

FAIRFIELD, the *Unquowa* of the Indians, a post town and port of entry of Connecticut, and capital of the above county, is pleasantly situated on Mill-Run, a little above its entrance into Long-Island sound, 22 miles S. W. by W. of New-Haven, and 64 from New York. It contains about 200 houses, a neat Congregational church, and a court-house. About 4 miles N. W. of the body of the town, and in the township, is the beautiful parish of Greenfield, in which is a flourishing academy. A high eminence in the centre of the parish commands a delightful prospect. Fairfield was settled from Weathersfield in 1639, and in 1736 contained 400 families. It was burnt by a party of tories and British, under the command of gov. Tryon, in 1777; the loss sustained, amounted to upwards of £.40,000. Fairfield carries on a considerable trade to the W. Indies. The exports for one year, ending Sept. 30th, 1794, amounted to 77,425 dollars.—*ib.*

FAIRFIELD, a township in Westmoreland co. Pennsylvania.—*ib.*

FAIRFIELD *Co.* in Camden district, S. Carolina, between Wateree river which divides it from Lancaster co. and Broad river which separates it from Newbury and Union counties. It contains 6138 white inhabitants, and 1485 slaves. Its chief town is Winnsborough.—*ib.*

FAIRHAVEN, in Bristol co. Massachusetts, lies on the N. W. side of Buzzard's bay, and on the eastern side of Accushnet river, opposite to Bedford.—*ib.*

FAIRHAVEN, a considerable township in Rutland co. Vermont, N. W. of Poultney. It contains 545 inhabitants, and is 51 miles N. of Bennington.—*ib.*

FAIRLEE, a township in Orange co. Vermont, on the W. bank of Connecticut river, 16 miles N. of Dartmouth College. The township is hilly, but of a good soil, and has several glades of excellent land. It contains 463 inhabitants.—*ib.*

FAIR WEATHER, CAPE, on the E. coast of Patagonia, in S. America, lies northerly from Cape Virgin Mary. S. lat. 51. 45. W. long. from Greenwich 68. 10.—*ib.*

FALCONRY is a species of sport, about the antiquity of which, there has been some dispute. Under the word HAWKING (*Encycl.*) we have deduced what we thought sufficient evidence of its being practised among the Thracians, and likewise among the Britons before the invasion of this island by the Romans. Flavius Blondus, however, and Laurentius Valla, both writers of the 15th century, and the latter, one of the most learned men of his time, affirm that no nation or people were accustomed to catch either land or water-fowls with any rapacious bird trained for the purpose.

We were pleased to see our own opinion, so different from this, completely established by the learned labours of Professor Beckmann. So early (says he) as the time of Ctesias (and he refers to the page and edition of his author) hares and foxes were hunted in India by means of rapacious birds. The account of Aristotle*, however, is still more to the purpose, and more worthy of notice. "In Thrace (says he) the men go out to catch birds with hawks. The men beat the reeds and bushes which grow in marshy places, in order to raise the small birds, which the hawks pursue and drive to the ground, where the fowlers kill them with poles." The same account is to be found in another book ascrib-ed

* *Hist. Animal*, lib. ix. cap. 6.

Falconry. ed alſo to Ariſtotle, and which appears, at any rate, to be the work of an author not much younger. Reſpecting Thrace, which is ſituated above Amphipolis, a wonderful thing is told, which might appear incredible to thoſe who had never heard it before. It is ſaid that boys go out into the fields, and purſue birds by the aſſiſtance of hawks. When they have found a place convenient for their purpoſe, they call the hawks by their names, which immediately appear as ſoon as they hear their voices, and chaſe the birds into the buſhes, where the boys knock them down with ſticks and ſeize them. What is ſtill more wonderful, when theſe hawks lay hold of any birds themſelves, they throw them to the fowlers; but the boys, in return, give them ſome ſhare of the prey. *De mirabilibus auſcultat.* cap. 128.

In this paſſage, there are two additions which render the circumſtance ſtill more remarkable. The firſt is, that the falcons appeared when called by their names; and the ſecond, that of their own accord they brought to the fowlers whatever they caught themſelves. Nothing is here wanting but the Spaniel employed to find out game, the hood which is put upon the head of the hawk while it ſtands on the hand, and the thong uſed for holding it, to form a ſhort deſcription of falconry as ſtill practiſed. Our falconers, when they have taken the bird from the hawk, give him, in return, a ſmall ſhare of it; and in the like manner the Thracian hawks received ſome part of their booty.

Other writers after Ariſtotle, ſuch as Antigonus, Ælian, Pliny, and Phile, have alſo given an account of this method of fowling. Ælian, who ſeldom relates any thing without ſome alteration or addition, ſays, that in Thrace nets were uſed, into which the birds were driven by the hawks; and in this he is followed by the poet Phile. Ælian, alſo, in another place deſcribes a manner of hunting with hawks in India, which, as we are told by ſeveral travellers, is ſtill practiſed in Perſia, where it is well underſtood, and by other eaſtern nations.

The Indians (ſays he) hunt hares and foxes in the following manner: They do not employ dogs, but eagles, crows, and, above all, kites, which they catch when young, and train for that purpoſe. They let looſe a tame hare or fox, with a piece of fleſh faſtened to it, and ſuffer theſe birds to fly after it, in order to ſeize the fleſh, which they are fond of, and which, on their return, they receive as the reward of their labour. When thus inſtructed to purſue their prey, they are ſent after wild foxes and hares in the mountains; theſe they follow in hopes of obtaining their uſual food, and ſoon catch them and bring them back to their maſters, as we are informed by Cteſias. Inſtead of the fleſh, however, which was faſtened to the tame animals, they receive as food the entrails of the wild ones which they have caught.

It ſeems, therefore, that the Greeks received from India and Thrace the firſt information reſpecting the method of fowling with birds of prey; but it does not appear that this practice was introduced among them at a very early period. In Italy, however, it muſt have been very common, for Martial and Apuleius ſpeak of it as a thing every where known; the former calls a hawk the fowler's ſervant.

The Profeſſor traces the hiſtory of this art with great learning down to the preſent time. It was carried to the higheſt perfection at the principal courts of Europe (he ſays) in the 12th century, when the ladies kept hawks, which were as much fondled by thoſe who wiſhed to gain their favour as lap-dogs are at preſent. Among the oldeſt writers on falconry as an art he reckons Demetrius, who about the year 1270 was phyſician to the Emperor Michael Paleologus. His book, written in Greek, was firſt printed at Paris in 1612 with a Latin tranſlation; but its precepts (ſays our author) would be thought of very little value at preſent. For an account of the modern art of falconry ſee *Encyclopædia*.

Falk. FALK (John Peter), known to the world as one of the ſcientific travellers employed by the late Empreſs of Ruſſia to explore her vaſt dominions, was born in Weſtrogothia, a province in Sweden, about the year 1727. He ſtudied medicine in the univerſity of Upſal, and went through a courſe of botany under the celebrated Linnæus, to whoſe ſon he was tutor. He publicly defended the diſſertation (A) which that famous botaniſt had compoſed on a new ſpecies of plants, which he called *aſtromeria*.

In the year 1760, he was ſo deeply affected with depreſſion of ſpirits, that M. de Linné, in the view of obliging him to take exerciſe and diſſipation, ſent him to travel over the iſland of Gothland, to make a collection of the plants it produces, and the various kinds of corals and corallines which the ſea leaves on its ſhores. This voyage was attended with no diminution of his diſtemper, which found a continual ſupply of aliment in a ſanguine melancholy temperament, in a too ſedentary way of life, and in the bad ſtate of his finances.

Profeſſor Forſkael having left Upſal for Copenhagen in 1760, Falk followed him thither in the deſign of applying, by the advice of M. de Linné, to be appointed aſſiſtant to M. Forſkael in his famous journey thro' Arabia; but, notwithſtanding all the pains that M. Œder, and ſeveral other men of literary reputation at Copenhagen, took in his behalf, his application failed, as the ſociety that were to go on that important expedition was already formed. Obliged, with much diſcontent, to return, he herboriſed as he travelled, and enriched the Flora Suecica with ſeveral new diſcoveries.

A man in office at St Peterſburgh having written to M. Linné to ſend him a director for his cabinet of natural hiſtory, M. Falk accepted the poſt, which led him to the chair of profeſſor of botany at the apothecaries garden at St Peterſburg, a place that had been long vacant. His hypocondriac complaint ſtill continued to torment him. When the Imperial academy of ſciences was preparing in 1768 the plan of its learned expeditions, it took M. Falk into its ſervice, though his health was uncertain. He was recalled in 1771; but having got only to Kaſan in 1773, he there obtained permiſſion to go and uſe the baths of Kiſliar, from which he returned again to Kaſan at the end of the year, with his health apparently better.

But his diſeaſe ſoon returned with redoubled violence. From the month of December 1773, he had never

(A) In the collection known under the title of *Linnæi Amœnitates Academicæ*.

never quitted his bed, nor taken any other nourishment than bread dried in the Swedish manner (knækebrœd), of which he scarcely took once a day some mouthfuls dipped in tea. At first he received the visits of a few friends, but afterwards denied himself to them, and was reduced to the strictest solitude. When M. Georgi, member of the society of natural history at Berlin, who had been destined to assist and relieve the professor in the duties of his expedition, went to see him on this occasion, nothing seemed left of him but a skeleton of a wild and terrifying aspect. The few words he drew from him consisted in complaints, occasioned by a host of diseases which kept his body in torture, and threw him into the most cruel sleeplessness. The last evening M. Georgi kept him company till midnight. He spoke little, and said nothing that could give reason to suspect the design he was meditating. His hunter, and at the same time his trusty servant, offered to sit up with him the night; but he could not be persuaded to consent.

M. Georgi being requested the next day, March 31, to come to the lodging of the unfortunate gentleman, he found him lying before his bed, covered with blood; beside him lay a razor, with which he had given himself a slight wound in the throat, the fatal pistol, and a powder horn; all together presenting a tremendous spectacle. He had put the muzzle of the pistol against his throat, and resting the pommel upon his bed, he discharged the contents in such a manner, that the ball, having gone through his head, had stuck in the ceiling. His soldier had seen him still sitting up in his bed at four o'clock, at which time he usually fell into a short slumber. In his chamber was found a note written the evening before, betraying throughout the distracted state of his mind, but nothing declaratory of his design, or that was of any importance.

M. Falk, like all hypochrondriac persons, was not very communicative, and on certain occasions was distrustful. But, at the same time, he was of a sedate temper, complaisant, and upright, which made it a very easy matter to bear with him, and secure to him the indulgence of all his acquaintance. His extreme sobriety had enabled him to make some savings from his pay, though he was very beneficent; it was not, therefore, indigence that drove him to this act of violence. He was of a cold constitution, preferring solitude and quiet to society, to the company of his friends, and to ordinary amusements, which yet he did not shun, except in the latter period of his life. As to religion, he shewed on all occasions more respect for it than any strong effusions of zeal. It was solely to be ascribed to the violence of his distemper, and the weakness of mind which it brought on, that led him to put a period to his days. The fate of this unfortunate scholar was generally and justly lamented.

His papers were found in the greatest disorder. They contain, however, very useful and important relations. He particularly made it his business to inquire about the Kirguises, and other Tartarian nations, and as he frequently remained for the space of nine months together in the same place, he was enabled to procure satisfactory notions concerning the objects of his investigations. The Imperial academy, in 1774, appointed Professor Laxmann to arrange his manuscripts in order for publication; which was done accordingly.

FALLING *Spring*, a branch of James river in Virginia, where it is called Jackson's river, rising in the mountain, 20 miles S. W. of the Warm Spring. The water falls over the rock 200 feet, which is about 50 feet higher than the fall of Niagara. Between the sheet of water and the rock below, a man may walk across dry.—*Morse.*

FALMOUTH, a township, formerly including Portland, in Cumberland co. Maine, containing 2991 inhabitants. It is situated on Casco bay, 120 miles N. N. E. of Boston. Incorporated in 1718.—*ib.*

FALMOUTH, a township in Hants co. Nova-Scotia; situated on the S. E. side of the Basin of Minas, opposite Windsor, 28 miles N. W. of Halifax.—*ib.*

FALMOUTH, a maritime township in Barnstable co. Massachusetts, situated on the N. E. part of the Vineyard sound, on the W. side of the bay of its name; 77 miles S. E. by S. of Boston, 18 from Sandwich, and 9 from Holme's Hole. It was incorporated in 1686, and contains 1637 inhabitants. N. lat. 41. 33. W. long. 70. 35. It is a post town.—*ib.*

FALMOUTH, a post town in Stafford co. Virginia, situated on the N. bank of Rappahannock river, nearly opposite to Fredericksburg. It is irregularly built, and contains an Episcopalian church and about 150 houses. It is 23 miles S. W. of Dumfries, 70 N. by E. of Richmond, and 207 S. westerly of Philadelphia. Considerable quantities of tobacco are inspected here.

FALMOUTH, a town in Lancaster co. Pennsylvania, situated on the S. E. side of Conawago creek, 20 miles westerly of Lancaster. It has been lately laid out.—*ib.*

FALMOUTH, a town and harbor on the S. shore of the island of Antigua, in the West-Indies. It has English harbor on the E. and Rendezvous bay on the W.; and situated in St. Paul's parish, at the N. W. corner of the harbor, which is well fortified.—*ib.*

FALMOUTH, in the island of Jamaica, in the West-Indies, commonly called the Point, is situated on the S. side of Martha Brae harbor; and including the adjoining villages of Martha Brae and the Rock, is composed of 220 houses. Here 30 capital stationed ships load for Great-Britain, exclusive of sloops and smaller craft.—*ib.*

FALSINGTON, a village in Pennsylvania, in Bucks co. 28 miles N. E. of Philadelphia.—*ib.*

FAQUIER *Co.* in Virginia, is bounded N. by Loudon and E. by Prince William. It is about 55 miles long and 20 broad, and contains 17,892 inhabitants, of whom 6642 are slaves—*ib.*

FAREWELL, CAPE, the S. point of West Greenland, on the N. side of the entrance of Davis's straits, North America. N. lat. 59. 37. W. long. 42. 42. —*ib.*

FARMER (Richard D. D.), so well known as one of the commentators on Shakespeare, was a man of such pleasing, though singular manners, that we regret the very imperfect account which we must give of his life. One of us, who had the pleasure of being a little known to him, has been so much delighted with the natural ease and pleasantry of his conversation, that we made all the inquiries which we judged requisite to enable us to draw up such a biographical sketch of this agreeable man as might be acceptable to our readers, and not unworthy of his character; but these inquiries were made in vain. Those to whom we applied knew little more

of

Farmer. of the incidents of his life than what we had previously found in a miscellany, of which the writers seem to consider it as a principle of duty to vilify the character of every person, who, like Dr Farmer, is the friend of order, and the enemy of sudden or rapid innovations. To that miscellany, therefore, we must be beholden for many facts; but we shall certainly copy none of its malevolence.

Dr Farmer was born at Leicester 1735; but what was the station of his father we have not learned. Of his school education he received part, perhaps the whole, in his native town: and from school he was removed to the university of Cambridge, where he devoted himself chiefly to classical learning and the belles lettres. In 1757, he was admitted to the degree of bachelor of arts; in 1760, to that of master of arts; a bachelor of divinity in 1767, and a doctor of divinity in 1775, in which year he was also elected master of Emanuel on the decease of Dr Richardson, and principal librarian on the decease of Dr Barnardiston.

The disturbances in America having by this time become serious, the university of Cambridge, with numberless other loyal bodies, voted an address to the king, approving of the measures adopted by government to reduce the factious colonists to their duty. The address, however, was not carried unanimously. It was, of course, opposed by Jebbe, so well known for his free opinions in politics and religion, and by some others, of whom one man, a member of the caput, carried his opposition so far, as actually to refuse the key of the place which contained the seal necessary on such occasions. In this emergency, Dr Farmer, who was then vice-chancellor, is said to have forced open the door with a sledge-hammer; an exploit which his democratical biographers affect to redicule, by calling it *his courtly zeal*, and the occasion of all his subsequent preferments.

If it be indeed true, that he broke the door in pieces with his own hands, his conduct must be acknowledged to have been not very decorous; but if the office which he filled be taken into consideration, we apprehend it would be as difficult to prove that conduct essentially wrong, as to vindicate the obstinate arrogance of him who occasioned it. The seal was the property of the university, of which this outrageous supporter of the bill of rights was but an individual member. The univetsity had resolved that it should be employed for a certain purpose, which it was the duty of the vice-chancellor to carry into effect; and since the seal was refused to him, he had no alternative but to get possession of it by force. We hope, however, that he employed a servant to break the door; and, indeed, as vice-chancellor, he must have had so many servants at his command, that it is not conceivable he would wield the sledge-hammer himself.

Some time after this, he was made a prebendary of Canterbury, we believe through the recommendation of Lord North, then premier; and it was at Canterbury that the writer of this sketch had the happiness of being introduced to him, and witnessing his hospitality. After enjoying his prebend for several years, he resigned it on being preferred, by the present premier, to a residentiaryship of St Paul's; and we have reason to believe, that he declined a bishopric, which was offered to him as a reward for the constitutional principles which he was at pains to propagate, not only in his college, but, as far as his influence went, through the whole university.

It has been said, that the delights of the pipe and the bottle in Emanuel parlour outweighed, in his estimation, the dazzling splendor of the mitre; but he had other and better reasons for preferring a private to a public station. In early life, at least before he was advanced in years, he had felt the power of love, and had suffered such a disappointment as sunk deep in his mind, and for a time threatened his understanding. From that period, though he retained his faculties entire, he acquired some peculiarities of manner; of which he was so far conscious, as to be sensible that they would hardly become the character of a bishop; being likewise strongly attached to dramatic entertainments, which, if we mistake not, the English bishops never witness, and delighting in clubs, where he could have rational conversation without state or ceremony of any kind—he very wisely preferred his residentiaryship to the highest dignity in the church. At the time of his death, which happened in the autumn of 1797, he was a fellow of the Royal and Antiquarian Societies, master of Emanuel college, principal librarian of the public library in the university, one of the canons residentiary of St Paul's, chancellor of the diocese of Lichfield and Coventry, and prebendary of Worcester.

Though a good classical scholar, Dr Farmer has been celebrated only for that kind of literature which is connected with the English drama, and having a strong predeliction for old English writers, he ranked high among the commentators upon Shakespeare. His "Essay upon the Learning of Shakespeare," dedicated to Mr Cradock, the intelligent resident of Gumley-Hall in Leicestershire, has passed through several editions. This essay was, in fact, the first foundation of his fame, which an unconquerable indolence prevented him from carrying to that height to which the exercise of his literary talents could not have failed to raise it. So great indeed was his love of ease, that after having announced for subscriptions a history of Leicestershire, and actually begun to print it, rather than submit to the fatigue of carrying it through the press, he returned the subscriptions, and presented the MSS. and plates to Mr Nichols, the respectable printer of the Gentleman's Magazine, who has since carried on the history with a degree of spirit, ability, and industry, perhaps unprecedented in this department of literature.

Indolence and the love of ease were indeed the Doctor's chief characteristics; and to them, with the disappointment already mentioned, may be attributed a want of propriety in his external appearance, and in the usual forms of behaviour belonging to his station. The prevailing features of his character distinguished themselves by several oddities: There were three things, it was said, which the master of Emanuel loved, *viz.* old port, old clothes, and old books; and three things which no one could persuade him to perform, *viz.* to rise in the morning, to go to bed at night, and to settle an account. When in Cambridge, if an old house were pulled down, the master of Emanuel was always there in an old blue great coat, and a rusty hat. When in London, he was sure to be found in the same garb at an old book-stall, or standing at the corner of a dirty lane, poring through his glass at an old play bill.

 This

This character is not drawn by a friendly pencil; but it is nevertheless not unjust. His inattention to the common decencies of dress and behaviour was notorious, insomuch that, in the company of strangers, the eccentricity of his appearance and of his manners made him sometimes be taken for a person half crazed. The writer of this sketch saw him one morning at Canterbury dressed in stockings of unbleached thread, brown breeches, and a wig not worth a shilling; and when a brother prebendary of his, remarkable for elegance of manners, and propriety of dress, put him in mind that they were to attend on the archbishop, Dr Farmer replied, that it had totally escaped him; but he went home, and dressed himself like a clergyman. That he sat late reading, and occasionally drinking brandy and water, cannot be denied; and it is literally true, that he could not easily be prevailed upon to settle his accounts. His accounts with some of his pupils, when tutor of his college, were never settled to the day of his death; and the young gentlemen not unfrequently took advantage of this unconquerable indolence to borrow of him considerable sums, well knowing that there was little chance of a demand being ever made upon their parents. One gentleman, in particular, told a friend of ours, who was himself a pensioner of Emanuel, that when he left that college, he was near fifty pounds in debt to Dr Farmer; "a debt (said he) which I would have scrupulously paid, but, after repeated solicitations, I could get no bill from him."

Having been a warm partizan of government during the American war, it will readily be believed that Dr Farmer was the determined enemy of levellers and anarchists. He was such a Whig as those who placed King William on the throne; and of course deemed a violent Tory by our present republicans, of whom, to say the truth, he could hardly speak with temper. By his enemies he is admitted to have been a man of generosity. As he obtained money easily, so he parted with it easily. Whilst he was always ready to relieve distress, his bounty was frequently bestowed on the patronage of learned men and learned publications. He was, accordingly, a favourite with all good men who knew him. In his own college he was adored; in the university he had, for many years, more influence than any other individual; and, with all his eccentricities, his death was a loss to that learned body, which, in the opinion of some of its members, will not soon be made up.

FARMINGTON, a very flourishing township of excellent land, in Lincoln co. district of Maine, on Sandy river, 35 miles N. W. of Hallowell, 30 same course from Harrington, and 204 N. N. E. of Boston. Number of inhabitants, about 1200. A very few years since this township was a wilderness.—*Morse.*

Farmington, a large, pleasant, and wealthy town in Hartford co. Connecticut, 10 miles S. W. of Hartford city, 32 N. E. of New-Haven, and 22 E. of Litchfield. Farmington river, a water of Connecticut, meanders delightfully through charming intervales, which beautify and enrich this town. The houses, in the compact part of this town, stand chiefly on a street which runs N. and S. along the gentle declivity of a hill, which ascends E. of the intervales; about the centre of the street stands a large and handsome Congregational church. This town was settled as early as 1645, and its limits then were very extensive. Several towns have been since taken from it.—*ib.*

Farmington, a small river of Connecticut, which passes through the town of Farmington, where it receives Cambridge or Poquabock river, from the S. W. when it acquires the name of Windsor river and falls into Connecticut river in the town of Windsor, about 4 miles above Hartford city.—*ib.*

FASCINATION, the art of bewitching, enchantment, an unseen inexplicable influence. Under the title Serpens (*Encycl.* n° 22) we have mentioned several instances of the fascinating power of the rattle-snake, which were related by men of character, and certainly gained some degree of credit among men of science. In Vaillant's New Travels into the Interior Parts of Africa, an account is given of similar instances of fascination by African servants, some of them witnessed by himself, and others reported to him by men of veracity.

On the confines of the European colony, at a place called *Swart-land*, our traveller saw a shrike on the branch of a tree, tremble as if in convulsions, whilst it uttered the most piercing cries of distress. Closer attention led him to discover upon the next branch of the same tree a large serpent, that, with stretched-out neck, and fiery eyes, though perfectly still, was gazing on the poor animal. He shot the serpent; but, in the mean-time, the bird had died. Having measured the distance between the place where the shrike was seen in convulsions and that occupied by the serpent when it was shot, he found it to be three feet and a half; which convinced him and his attendants that the bird had not died either from the bite or the poison of its enemy. Indeed he stripped it before the whole company, and made them observe that it was untouched, and had not received the slightest wound.—In another district of Africa, during the course of the same travels, he saw a small mouse die in convulsions, occasioned by the fascinating power of a serpent, at the distance of two yards from it; and when he consulted his Hottentots upon this incident, they expressed, he says, no sort of astonishment, but assured him that the serpent had the faculty of attracting and fascinating such animals as it wished to devour.

We have already had occasion to remark how regardless this author is of inconsistencies in his narrative; and we perceive something like an inconsistency in the narratives before us. Though his Hottentots expressed no surprise at the fascination of the mouse, and declared that nothing was more common, he says expressly, that to those who witnessed the fascination of the shrike, the fact appeared so extraordinary, that they could hardly believe it, even after they had seen it.

The most wonderful instance of fascination which we have anywhere met with, was that of a Captain in the Dutch service at the Cape, who, after assuring our traveller that it is an event which happens very frequently, proceeded thus: "My testimony ought to have the more weight, as I had once nearly become myself a victim to this fascination. While in garrison at Ceylon, and amusing myself, like you, in hunting in a marsh, I was, in the course of my sport, suddenly seized with a convulsive and involuntary trembling, different from any thing I had ever experienced, and at the same time was strongly attracted, and in spite of myself,

to

Fascination to a particular ſpot of the marſh. Directing my eyes to this ſpot, I beheld, with feelings of horror, a ſerpent of an enormous ſize, whoſe look inſtantly pierced me. Having, however, not yet loſt all power of motion, I embraced the opportunity before it was too late, and ſaluted the reptile with the contents of my fuſee. The report was a taliſman that broke the charm. All at once, as if by a miracle, my convulſion ceaſed; I felt myſelf able to fly; and the only inconvenience of this extraordinary adventure was a cold ſweat, which was doubtleſs the effect of my fear, and of the violent agitation my ſenſes had undergone."

This inſtance of faſcination differs in one very material circumſtance from the two ſomewhat ſimilar inſtances mentioned in the *Encyclopædia*. In both theſe, the eyes of the perſons faſcinated were fixed on the eyes of the ſnake; but here the Dutch Captain was ſtrongly attracted towards the ſerpent before he ſaw, or even ſuſpected that ſo formidable an enemy was in his neighbourhood. If the ſtory therefore be true, the effect which he deſcribes could not poſſibly have been the effect of fear, but of ſome unſeen influence on his whole nervous ſyſtem.

The ſubject has of late attracted the attention of men of ſcience, whoſe local ſituation gives them an opportunity of making experiments upon different ſerpents, with a view to aſcertain whether they really poſſeſs or not this moſt unaccountable of all powers. In the year 1796, was printed at Philadelphia, *a Memoir concerning the Faſcinating Faculty which has been aſcribed to the Rattle-ſnake, and other American Serpents*, by Benjamin Smith Barton, M. D. Profeſſor of natural hiſtory and botany in the univerſity of Pennſylvania. In this memoir, the manner in which the faſcinating power is ſuppoſed to be exerted is thus ſtated by the ingenious profeſſor:

"The ſnake, whatever its ſpecies may be, lying at the bottom of the tree or buſh upon which the bird or ſquirrel ſits, fixes its eyes upon the animal it deſigns to faſcinate or enchant. No ſooner is this done, than the unhappy animal is unable to make its eſcape. It now begins to utter a moſt piteous cry, which is well known by thoſe who hear it, and underſtand the whole machinery of the buſineſs, to be the cry of a creature enchanted. If it is a ſquirrel, it runs up the tree for a ſhort diſtance, comes down again, then runs up, and, laſtly, comes lower down. 'On that occaſion (ſays an honeſt, but rather credulous writer*), it has been obſerved, that the ſquirrel always goes down more than it goes up.' The ſnake ſtill continues at the root of the tree, with its eyes fixed on the ſquirrel, with which its attention is ſo entirely taken up, that a perſon accidentally approaching, may make a conſiderable noiſe without the ſnake's ſo much as turning about. The ſquirrel, as before mentioned, comes always lower, and at laſt leaps down to the ſnake, whoſe mouth is already wide open for its reception. The poor little animal then, with a piteous cry, runs into the ſnake's jaws, and is ſwallowed at once, if it be not too big; but if its ſize will not allow it to be ſwallowed at once, the ſnake liks it ſeveral times with its tongue, and ſmoothens it, and by that means makes it fit for ſwallowing."

* *Profeſſor Peter Kalm.*

From Dr Barton's memoir, it appears that the North American Indians are by no means of one opinion reſpecting the faſcinating power of the rattle-ſnake. Some intelligent friends of his, well acquainted with the manners, religious opinions, and ſuperſtitious prejudices of thoſe people, informed him, that though they had often heard the Indians ſpeak of the ingenuity of theſe reptiles in catching birds, ſquirrels, &c. they did not recollect having ever heard them ſay that ſnakes *charm* birds. On the other hand, however, a Mohegan Indian told the Doctor himſelf, that the Indians are of opinion, that the rattle-ſnake can charm or bewitch, ſquirrels and birds, and that it does this with its rattle, which it ſhakes, thereby inviting the animals to deſcend from the trees, after which they are eaſily caught. According to this Indian, his countrymen do not think that the ſnake, in any manner, accompliſhes the buſineſs with its eyes. A Choktah Indian aſſured the Doctor, that the rattle-ſnake does charm birds, &c.; but he was honeſt enough to confeſs, that he did not know in what manner it does it. The interpreter, through whom the converſation was carried on with this Indian, ſaid that the ſnake charms by means of its rattle.

This opinion of the interpreter was the opinion of Dr Mead. That eminent naturaliſt, controverting, about fifty years ago, the common opinion, that Providence has furniſhed the rattle-ſnake with its rattle to give warning to travellers, was the firſt who aſſerted that this ſingular appendage is given to the animal to terrify ſquirrels and ſmall birds, which are then ſo ſtupified by the ſight of ſo formidable an enemy, that at length they drop down and become its prey; and that this is what the Indians call *faſcination*. The ſame opinion has been adopted by profeſſor Blumenbach of Gottingen, who, in his Manual of Natural Hiſtory, thus expreſſes himſelf on this curious ſubject:

"That ſquirrels, ſmall birds, &c. fall down ſpontaneouſly from trees into the mouth of the rattle-ſnake, lying below them, is an undiſputed fact; and is the leſs ſurpriſing, as the like phenomena have been remarked in regard to other ſnakes, and alſo toads, hawks, and cats; all of which, in certain circumſtances, as appears, have the power of drawing towards them ſmall animals, merely by fixing their eyes ſtedfaſtly on them. In regard to the rattle-ſnake, this effect is produced by the rattle in its tail, the hiſſing noiſe of which makes ſquirrels, &c. whether through curioſity, miſtake, or terror, ſeem to approach the animal as it were ſpontaneouſly. At any rate, I know, from the information of intelligent eye-witneſſes, that it is a common ſtratagem of the young ſavages in America to conceal themſelves in the buſhes, where they imitate the hiſſing noiſe of the rattle-ſnake, and by theſe means attract ſquirrels, which they are then enabled to catch."

To this opinion Dr Barton oppoſes an inſuperable objection. It is, that this faſcinating power is by no means peculiar to the rattle-ſnake. With regard to the ſtratagem of the ſavages, he thinks that Dr Blumenbach has been impoſed upon; as neither he, nor any other perſon of whom he made the inquiry, ever heard of ſuch a ſtratagem. The young Indians, he ſays, place a reed croſs-wiſe in their mouth, and by a tremulous motion of the lips, imitate the cry of young birds; by which means they entice the old ones, ſo that they can eaſily ſhoot them: And this practice may have given riſe to the ſtory of their imitating the hiſſing noiſe of the rattle-ſnake.

Some have ſuppoſed that ſerpents, under certain circumſtances,

cumſtances, emit from their bodies a ſtupifying vapour; and that it is this vapour which produces the effect called *faſcination:* But againſt this opinion Dr Barton alleges the following arguments: "I know, indeed (ſays he), that in ſome of the larger ſpecies of ſerpents, inhabiting South America and other countries, there is evolved in the ſtomach, during the long and tedious proceſs of digeſtion in theſe animals, a vapour or a gas, whoſe odour is intenſely fetid. I have not, however, found that this is the caſe with the rattle-ſnake, and other North American ſerpents, that I have examined. But my own obſervations on this head have not been very minute. I have made inquiry of ſome perſons (whoſe prejudices againſt the ſerpent tribe are not ſo powerful as my own), who are not afraid to put the heads and necks of the black ſnake, and other ſerpents that are deſtitute of venomous fangs, into their mouths, and have been informed, that they never perceived any diſagreeable ſmell to proceed from the breath of theſe animals. I have been preſent at the opening of a box which contained a number of living ſerpents, and although the box had been ſo cloſe as to admit but a very ſmall quantity of freſh air, although the obſervation was made in a ſmall warm room, I did not perceive any peculiarly diſagreeable effluvium to ariſe from the bodies of theſe animals. I am, moreover, informed by a member of this ſociety*, who has, for a conſiderable time, had a rattle-ſnake under his immediate care, that he has not obſerved that any diſagreeable vapour proceeds from this reptile. On the other hand, however, it is aſſerted by ſome creditable perſons of my acquaintance, that a moſt offenſive odour, ſimilar to that of fleſh in the laſt ſtage of putrefaction, is continually emanating from every part of the rattle-ſnake, and ſome other ſpecies of ſerpents. This odour extends under certain circumſtances, to a conſiderable diſtance from the body of the animal. Mr William Bartram aſſures me, that he has obſerved 'horſes to be ſenſible of, and greatly agitated by it, at the diſtance of forty or fifty yards from the ſnake. They ſhewed (he ſays) their abhorrence by ſnorting, winnowing, and ſtarting from the road, endeavouring to throw their riders, in order to make their eſcape.' This fact, related by a man of rigid veracity, is extremely curious; and, in an eſpecial manner, deſerves the attention of thoſe writers who imagine that this fetid emanation from ſerpents is capable of affecting birds, at ſmall diſtances, with a kind of aſphyxy. It even gives *ſome* colour of probability to the ſtory related by Metrodorus, and preſerved in the Natural Hiſtory of Pliny‡.

* *American Philoſophical Society.*

‡ *Lib.* 28. *Cap.* 14.

Some experiments, however, which were made in Philadelphia a little before the Doctor compoſed his memoir, ſeem to have been deciſive not only as to the fetor, but as to every thing which reſembles faſcination in the rattle-ſnake. Birds which were put into a cage which contained a rattle-ſnake, flew or ran *from* the reptile, as though they were ſenſible of the danger to which they were expoſed. The ſnake made many attempts to catch the birds, but could ſeldom ſucceed. When a dead bird was thrown into the cage, the ſnake devoured it immediately. He ſoon caught and devoured a living mole, an animal much more ſluggiſh than the bird. Dr Barton himſelf ſaw a ſnow-bird (ſee EMBERIZE *Encycl.*) in a cage with a large rattle-ſnake. The little animal had been thus impriſoned for ſeveral hours when he firſt ſaw it, but it exhibited no ſigns of fear. It hopped about from the floor of the cage to its rooſt, and frequently perched on the ſnake's back. Its chirp was nowiſe tremulous, but perfectly natural. It ate the ſeeds which were put into the cage; and by its whole actions moſt evidently demonſtrated that its ſituation was not uneaſy.

Having thus diſpoſed of the doctrines of ſome of his predeceſſors, Dr Barton proceeds to ſay: "The reſult of not a little attention to the ſubject has taught me, that there is but one wonder in the buſineſs;—the wonder that the ſtory ſhould ever have been believed by a man of underſtanding and of obſervation." Faſcination, we are informed, is almoſt entirely limited to birds that build low, and "in almoſt every inſtance, I found that the ſuppoſed faſcinating faculty of the ſerpent was exerted upon the birds at the particular ſeaſon of their laying their eggs, of their hatching, or of their rearing their young, ſtill tender and defenceleſs. I now began to ſuſpect, that the cries and fears of birds ſuppoſed to be faſcinated originated in an endeavour to protect their neſt or young. My inquiries have convinced me that this is the caſe.

The rattle-ſnake, which is the lazieſt of all the ſerpent tribe, never moves in a ſpiral manner or climbs up trees; but the black ſnake, and ſome other ſpecies of the genus coluber, do. When impelled by hunger, and incapable of ſatisfying it by the capture of animals on the ground, they begin to glide up trees or buſhes upon which a bird has its neſt. The bird is not ignorant of the ſerpent's object. She leaves her neſt, whether it contains eggs or young ones, and endeavours to oppoſe the reptile's progreſs. In doing this, ſhe is actuated by the ſtrength of her inſtinctive attachment to her eggs, or of affection to her young. Her cry is melancholy, her motions are tremulous. She expoſes herſelf to the moſt imminent danger. Sometimes ſhe approaches ſo near the reptile that he ſeizes her as his prey. But this is far from being univerſally the caſe. Often ſhe compels the ſerpent to leave the tree, and then returns to her neſt.

It is a well known fact, that among ſome ſpecies of birds, the female, at a certain period, is accuſtomed to compel the young ones to leave the neſt; that is, when the young have acquired ſo much ſtrength that they are no longer entitled to all her care. But they ſtill claim ſome of her care. Their flights are aukward, and ſoon broken by fatigue. They fall to the ground, where they are frequently expoſed to the attacks of the ſerpent, which attempts to devour them. In this ſituation of affairs, the mother will place herſelf upon a branch of a tree or buſh, in the vicinity of the ſerpent. She will dart upon the ſerpent, in order to prevent the deſtruction of her young: but fear, the inſtinct of ſelf preſervation, will compel her to retire. She leaves the ſerpent, however, but for a ſhort time, and then returns again. Oftentimes ſhe prevents the deſtruction of her young, attacking the ſnake with her wings, her beak, or her claws. Should the reptile ſucceed in capturing the young, the mother is expoſed to leſs danger. For, whilſt engaged in ſwallowing them, he has neither inclination nor power to ſeize upon the old one. But the appetite of the ſerpent tribe is great: the capacity of their ſtomachs is not leſs ſo. The danger of the mother is at hand when the young are devoured. The

ſnake

snake seizes upon her: and this is the castrophe, which crowns the tale of fascination!

FAVOURABLE *Lake*, in N. lat. 52. 48. W. long. 93. 10. is the source of two large rivers, at the mouth of one of which, emptying into Winnipeg lake, stands the Canadian house. The other is the S. W. branch of Severn river.—*Morse*.

FAUSSE-BRAYE, in fortification, an elevation of earth, about three feet above the level ground, round the foot of the rampart on the outside, defended by a parapet about four or five fathoms distant from the upper parapet, which parts it from the berme and the edge of the ditch. The fausse-braye is the same with what is otherwise called *Chemin des rondes*, and *Basse enceinte*; and its use is for the defence of the ditch.

FAWN, a township in York co. Pennsylvania.—*Morse*.

FAYETTE, a settlement in Tioga co. New-York, between the Unadilla and the main branch of the Chenengo. It is laid out into 100 lots of a square mile each, as nearly as the ground will permit.—*ib*.

FAYETTE, *Co.* in Pennsylvania, is bounded N. by Westmoreland, S. by part of Maryland and Virginia, and W. by Monongahela river. It is 39 miles in length and 29 in breadth, and contains 473,280 acres; divided into 11 townships, of which Union is the chief. The number of inhabitants is 13,325, of whom 282 are slaves.—*ib*.

FAYETTE, a district of N. Carolina, comprehending 6 counties, viz. Moore, Cumberland, Sampson, Richmond, Robeson, and Anson. It is bounded N. by Hillsborough, S. E. by Wilmington and Newbern, W. by Salisbury, and S. by the state of S. Carolina. It is 120 miles in length, and 50 in breadth, and contains 34,020 inhabitants, of whom 5,678 are slaves.—*ib*.

FAYETTE, a co. of Kentucky, surrounded by Clarke, Bourbon, Scott, Franklin, Woodford, Maddison, and Mercer counties. Chief town Lexington.—*ib*.

FAYETTEVILLE, so called in honor of the Marquis La Fayette, a flourishing post town of North-Carolina, the seat of justice for the above district, and pleasantly situated in Cumberland co. on the W. side of the N. W. branch of Cape Fear river, nearly at the head of navigation, and 100 miles above Wilmington, and 61 southerly of Raleigh. On the bank of the river, stand a few buildings and the tobacco ware houses, which have received in one season 6000 hhds. of tobacco, equal in quality to that of Petersburg. The compact part of the town is situated about a mile from the river, near the junction af Blount's and Cross creek; on which last it is chiefly erected, and from that circumstance was formerly named Cross Creek. On both sides the creek are about 400 houses, 2 handsome edifices for the supreme, district, and county courts, and the meetings of the town officers and its citizens. The Free Masons' lodge is also a large and handsome building. The town is regularly laid out, and its principal streets are 100 feet wide. Here are three mills, two considerable distilleries and breweries, and several extensive tan yards. The trade to Wilmington is very considerable, to which it sends down tobacco, wheat, flour, beef, pork, flax-seed, hemp, cotton, butter, lumber, staves, naval stores, &c. The boats used in transporting these articles to Wilmington, contain about 120 barrels, and make their returns of European and India goods, &c. in from 10 to 20 days. The situation of the town is agreeable and healthy, and well adapted for establishing manufactories. The country immediately round the town is considerably elevated, and the soil dry and barren; but near the water courses, which are numerous, the soil is as rich as any in the state. Since the fire in 1792, which destroyed many houses, the people begin to build with brick, which are made here of a good quality, and sold reasonably. The town stands in a settlement of Scotch Highlanders, and is 55 miles N. W. of Camden in S. Carolina, 100 S. W. of Tarborough, 147 S. W. by S. of Halifax, 379 S. by W. of Washington city, and 526 S. W. by S. of Philadelphia.—*ib*.

FEAR POINT, CAPE, at the mouth of Cape Fear river in N. Carolina, 4 miles S S. E. of the light-house on Bald Head.—*ib*.

FEATHER-EDGED, is a term used by workmen for such boards as are thicker on one edge, or side, than on the other.

FEDERALSBURG, a village in Maryland, on the E. side of Chesapeak bay, situated on Marshy Hope creek, partly in Dorchester and partly in Caroline co. 5 miles E. N. E. of Hunting-Creek town, and about 20 N. E. of Cambridge.—*Morse*.

FE D'ANTIOCHIA, SANTA, the most northern town of Popayan, a district of Terra Firma, S. America. It is situated 200 miles N. of Popayan city, near the confines of the province of Carthagena, on the banks of St Martha river, and near 180 miles S. of its conflux with the Magdalena. Thither the inhabitants removed from Antiochia, 15 leagues from it, now an inconsiderable place, whereas Santa Fe d'Antiochia is a considerable place, and capital of the audience of Santa Fe.—*ib*.

FE DE BAGOTA, SANTA, the capital of New-Grenada, S. America, situated on the banks of the little river Pati, a water of the Magdalena; is 180 miles E. of the bottom of Bonaventura bay. It is an archbishop's see, and the seat of an university founded by king Philip III. in 1610. Near this city are gold mines. The air is temperate and healthful, and provisions plenty. S. lat. 4. 10. W. long. 74. 5.—*ib*.

FE, or FOY, SANTA, a place in the middle of Veragua, a province in the audience of Guatimala, in North America, where the king of Spain keeps officers for casting and refining gold. It stands at the source of a river which runs into the North Sea.—*ib*.

FE, SANTA, the capital of New-Mexico, in N. America. It is situated near the source of Rio del Nort, 130 leagues from its mouth, in the gulf of Mexico. It is said to be a rich and regularly built city, and a bishop's see. Baudrand makes it 9 leagues from the river. It is also called Santa Fe de Grenada: by others New-Mexico. N. lat. 36. W. long. 104.—*ib*.

FE, SANTA, a city of Paraguay, S. America, 150 leagues S. by S. W. of the city of Assumption. The inhabitants are chiefly employed in husbandry, grazing, and weaving cloth. They sell their productions and manufactures to good profit in Brazil. From hence is a road to Potosi in Peru, and to Corbuda in Tucumana; which being easy and convenient, is very advantageous to this place. The distance not being above 350 leagues. It stands on the W. side of Paraguay river. S. lat. 30. 45. W. long. 60 40.—*ib*.

FELTING,

Felting. Felting.

FELTING, the method of working up wool or hair into a kind of cloth or stuff, without either spinning or weaving it. In this country felting is little practised except in hat making; and as nine-tenths of those who are employed in the manufacturing of hats know nothing of the principles on which they proceed, the following observations on the mechanism of felting must to them be both agreeable and useful. They are by M. Monge, and taken from the *Annales de Chemie*.

If we examine, in a microscope, human hair, wool, the hair of a rabbit, hare, beaver, &c. however great the magnifying power of the instrument may be, the surface of each hair appears perfectly smooth and even; or at least, if any inequalities are to be perceived, they seem rather to arise from some difference in the colour and transparency of particular parts of these substances than from the irregularity of their surfaces; for their image, when viewed by a solar microscope, is terminated by even lines, without any roughness. The surface of these objects, however, is by no means smooth; on the contrary, it appears to be formed either of *lamellæ* which cover each other from the root to the point, pretty much in the same manner as the scales of a fish cover the animal from the head to the tail; or, more probably, of zones placed one over the other, like what is observed in the structure of horns: to this conformation it is, that the substances here treated of owe their disposition to what is called felting.

If, with one hand, we take hold of a hair by the root, and draw it between two fingers of the other, from the root towards the point, we are hardly sensible of any friction or resistance, nor can we distinguish any sound; but if, on the contrary, we hold the hair at the point, and draw it between the fingers, from the point towards the root, we are sensible of a resistance which did not exist in the former case; a sort of tremulous motion is likewise produced which is not only perceptible to the touch, but may also be distinguished by the ear.

It is evident therefore, that the texture of the surface of a hair is not the same from the root towards the point as from the point towards the root; and that a hair, when grasped, must offer more resistance in sliding or moving progressively towards the point than towards the root; *i. e.* in moving with its point foremost

If a hair, after being taken hold of by the fore finger and thumb, he rubbed by them, in the longitudinal direction of the hair, a progressive motion takes place, and this motion is always towards the root. This effect does not at all depend on the nature of the skin of the fingers or its texture; for if the hair be turned, so that the point is placed where the root was, the movement then becomes contrary to what it was before; that is to say, it is always directed towards the root.

What is observed, in the above instance, is entirely analogous to what happens when country children, by way of sport, introduce an ear of rye or barley between the wrist and the shirt, the points of the beards of which are directed outwards. By the various motions of the arm, this ear, sometimes catching against the shirt, sometimes against the skin, takes a progressive motion backwards, and soon gets up to the arm-pit. It is very clear that this effect is produced by the beards of the ear, and indeed chiefly by the asperities upon those beards; which, being all directed towards the point, do not permit the ear to move in any other direction than towards that part to which it was united to the stalk. There is no doubt that it is the same with respect to hair; and that its surface is beset with asperities, which, being laid one upon the other, and turned towards the points, permit no motion but towards the root.

A tight knot, made in the middle of a hair, is very difficult to untie by the usual means, on account of the extreme thinness of the hair; but if we place the hair in the bend of the hand, so that the knot is in a line with the little finger, and, after grasping the hair by closing the hand, we strike the fist several times against the knee, the asperities of one end of the hair being now in a contrary direction to those of the other, each of the ends recedes a little, one of them one way, the other the contrary way; the knot is thereby opened, and, by introducing a pin into the eye which is formed, it is very easy to finish untying it.

These observations, which it would be useless to multiply, relate to long hair, that having been taken as an example; but they apply with equal propriety to wool, furs, and in general to every kind of animal hair. The surface of all these is therefore to be considered as composed of hard *lamellæ* placed one upon another, like tiles, from the root to the point; which *lamellæ* allow the progressive motion of the hair towards the root, but prevent a similar motion towards the point.

From what has been said, it is easy to explain why the contact of woolen stuffs is rough to the skin, while that of linen or cotten cloths is smooth; the reason is, the asperites upon the surface of the fibres of the wool (notwithstanding the flexibility of each particular fibre), by fixing themselves in the skin, produce a disagreeable sensation, at least till we are accustomed to it; whereas the surface of the fibres of hemp or flax, of which linen is made, being perfectly smooth, do not cause any such sensation. It is also evident, that the injury arising to wounds or sores, from the application of wool, does not proceed from any chemical property, but is occasioned solely by the conformation of the surface of the fibres; the asperities of which attach themselves to the raw and exposed flesh, which they stimulate and irritate to such a degree as to produce inflammation.

This conformation is the principal cause of that disposition to what is called felting, which the hair of all animals in general possesses.

The hatter, by striking the wool with the string of his bow (see HAT, *Encycl.*), separates the hairs from each other, and causes them to spring up in the air; the hairs fall again on the table, in all possible directions, so as to form a layer of a certain thickness, and the workman covers them with a cloth, which he presses with his hands, moving them backwards and forwards in various directions. This pressure brings the hairs against each other, and multiplies their points of contact; the agitation of them gives to each hair a progressive motion towards the root; by means of this motion the hairs are twisted together, and the *lamellæ* of each hair, by fixing themselves to those of other hairs which happen to be directed the contrary way, keep the whole in that compact state which the pressure makes it acquire. In proportion as the mass becomes compact, the pressure of the hands should be increased; not only to make it more close, but also to keep up the progressive

Felting.

progressive motion and twisting of the hairs, which then takes place with greater difficulty: but throughout the whole of this operation, the hairs fix themselves only to each other, and not to the cloth with which they are covered, the fibres of which, as we have already said, are smooth, and have not that disposition to felting which we have described above.

It may not be amiss here to explain why that hair which is intended for making hats is always cut off with a sharp instrument (although that cannot be done without losing a part of its length), and not plucked out by the roots, as might be done after softening the skin: the reason is, the bulb of the hair, which in the latter case would come out with it, would render that end which was fixed in the skin thick and obtuse; and it would consequently be less disposed to introduce itself among the contiguous hairs, and to contribute by its progressive motion to the contexture of the mass.

The above described conformation of the surface of hairs and wool is not the only cause which produces their disposition to felting. It is not sufficient that every hair possesses the forementioned tendency to move progressively towards the root, and that the inclined *lamellæ*, by hooking themselves to each other, preserve the mass in that state to which compression has brought it; but it is also necessary that the hairs should not be straight, like needles; if they were so, pressing and rubbing them together would merely cause them to continue their progressive motion, without changing their direction: and the effect of those operations would only be to make them move from the centre of the mass, without producing any compactness in it. Every hair must therefore be twisted or curled in such a manner that the extremity which is towards the root may be disposed to change its direction perpetually, to twist itself about other hairs, and to incline towards itself again, in case it should be determined thereto by any change in the position of the rest of its length. It is because wool has naturally this crooked form that it is so proper for felting, and that it may be made use of for that purpose without undergoing any previous preparation.

But the hairs of the beaver, the rabbit, the hare, &c. being naturally straight, cannot be employed alone in felting till they have undergone a preliminary operation; which consists in rubbing or combining them, before they are taken off the skin, with a brush dipped in a solution of mercury in aquafortis (nitric acid). This liquor, acting only on one side of the substance of the hairs, changes their direction from a right line, and gives them that disposition to felting which wool naturally possesses.

When the hairs are not intended to enter into the body of the mass, but are only to be employed in making a sort of external coating, such as is sometimes given to the outer surface of hats, the operation just mentioned need not be performed; but the felt on which they are to be fixed being finished, the hair is uniformly spread upon the surface to which the coating is to be applied; and, being covered with a cloth, it is pressed with the hands, and agitated for a certain time. By these means, the hairs introduce themselves, by the root, a certain depth into the felt, and are there fixed by their *lamellæ* in such a manner as not to be easily extracted. A particular direction is afterwards given to them by means of a brush, and they are made to keep this direction by having a hot iron passed over them. If the agitation were continued for a longer time, these hairs, not having their straightness destroyed by the operation before describe l, would pass entirely through the felt, going out at the opposite surface, as each hair follows exactly the direction it acquired at the beginning.

Fer, Point au || Fergusson.

It is owing to the very same circumstances which make wool and hair capable of felting, that woollen cloth is thickened by fulling. See FULLING in this Supplement.

FER, POINT AU, on the W. coast of lake Champlain, lies in Clinton co. nearly 5 miles S. of the division line between New-York and Lower Canada, and 25 miles S. of St. John's. The British occupied a barrack here, furnished with one field piece, a few men, and a subaltern officer. It has been given up according to treaty.—*Morse.*

FERDINAND NARONKA, an island on the coast of Brazil, South America, lies in S. lat. 3. 56. W. long. 32. 43.—*ib.*

FERGUSSON (Robert), who at an early period of life obtained a considerable degree of celebrity as a Scottish poet, was born at Edinburgh on the 5th of September 1750, according to a manuscript account of him with which we have been favoured by a relation. In the biographical sketch prefixed to the Perth edition of his poems he is said to have been born in 1751.

His father William Fergusson possessed, as well as himself, some talents for poetry; but, marrying early, and being wiser than his son, he abandoned the muses for trade, and was employed in different mercantile houses, first in Aberdeen, and afterwards in Edinburgh. At the time of his death, he was an accountant in the British linen hall, but never acquired any thing like opulence.

During the years of infancy and childhood, the constitution of our poet was so weak, that little hopes were entertained of his arriving at manhood. By the care, however, and attention of his parents, he gradually acquired strength, and at the age of six was put to an English school, where his proficiency in reading and reciting was uncommonly great. At the age of seven he was sent to the high school of Edinburgh, where he continued four years, and with very little labour made a rapid progress in the knowledge of the Latin tongue; but for some reason or other he was removed from the high school to the grammar school of Dundee, whence, after two years he was sent to the university of St Andrews. A gentleman of the name of Fergusson had left bursaries in that university for the education of two boys of the same name; and Mr William Fergusson having with difficulty obtained one of them for his son, was induced to educate him at St Andrews in preference to Edinburgh.

Though at no period of his life a severe student, our poet's attainments in science were such as to keep alive in the university the hopes which had been formed of him at school; and he was confessedly the first mathematician of his standing. On this account we are told that he became the favourite of Dr Wilkie, who was then professor of natural philosophy in the university of St Andrews; but it is not improbable that the Doctor valued him as much for his poetical genius as for his skill

ſkill in geometry; for Wilkie was a poet himſelf, and Mr Ferguſſon had already written ſeveral ſmall poems which attracted conſiderable notice, as well from the profeſſors as from his fellow-ſtudents. But whatever was the bond of union, Dr Wilkie patroniſed the youthful poet; and the poet ſhewed afterwards that he was not ungrateful. Upon the Doctor's death, he publiſhed, in the Scottiſh dialect, a beautiful eclogue to his memory, in which the peculiar merits of that eccentric genius are appreciated with great judgment. See Wilkie, in this Supplement.

During the laſt winter that he reſided in St Andrews, our poet had collected materials for a tragedy on the death of Sir William Wallace, and had even completed two acts of the play; but having ſeen a ſimilar work on the ſame ſubject, he abandoned his deſign; "becauſe (ſaid he to a friend) whatever I publiſh ſhall be original, and this tragedy might be conſidered as a copy."

Having finiſhed his ſtudies at the univerſity, he returned to Edinburgh without reſolving on any permanent employment. His father had deſigned him for the church; but he was now dead, and our author turned a deaf ear to the intreaties of his mother, and of every other friend who endeavoured to perſuade him to fulfil his father's intention. He was then adviſed to ſtudy phyſic; but he declined it, becauſe, he ſaid, that, when reading the deſcription of diſeaſes, he fancied that he felt the ſymptoms of them all in himſelf. To the law, however, he could not ſtart the ſame objection; and he began to ſtudy it, but made no progreſs. At this his relation and the editor of his poems expreſs no ſurpriſe; for, according to them, it was a ſtudy the moſt improper for him, as it could not be expected that a genius ſo lively would ſubmit to the drudgery of that dry and ſedentary profeſſion.

That the law was a very improper profeſſion for a man of his narrow fortune is indeed true; but we truſt that his two biographers will not conſider us as intending any offence to them, if we embrace the preſent opportunity of expoſing the folly of a very common remark, that a lively genius cannot ſubmit to what is abſurdly called a dry ſtudy. We might inſtance different lawyers at our own bar, who, with great poetical talents in their youth, have riſen to the ſummit of their profeſſion; but to avoid perſonal diſtinctions at home, we ſhall take our examples from England. The genius of the late Earl of Mansfield was at leaſt as lively as that of Mr Ferguſſon, and if he had pleaſed he could have been equally a poet; yet he ſubmitted to the drudgery of ſtudying a law ſtill drier than that of Scotland. To the fine taſte of Atterbury biſhop of Rocheſter, and to his claſſical compoſitions both in proſe and verſe, no man is a ſtranger who is at all converſant in Engliſh literature: yet that elegant ſcholar and poet, after he had riſen to the dignity of Dean of Carliſle, ſubmitted to the drudgery of ſtudying, through the medium of barbarous Latin, the eccleſiaſtical law of England from the earlieſt ages; and declared, that by dint of perſeverance he came in time to reliſh it as much as the ſtudy of Homer and Virgil. Whatever be thought of Milton's political principles, no man can read his controverſial writings, and entertain a doubt but that he could have ſubmitted to the drudgery of ſtudying the law.

The truth is, and it is a truth of great importance, that a man of real vigour of mind may bring himſelf to delight in any kind of ſtudy which is uſeful and honourable. Such men were Lord Mansfield, the Biſhop of Rocheſter, and Milton; but, whether through ſome radical defect in his nervous ſyſtem, or in conſequence of early diſſipation, Mr Ferguſſon, with many eſtimable qualities was ſo utterly deſtitute of this mental vigour, that rather than ſubmit to what his friends call drudgery, he ſeems to have looked with a wiſhful eye to ſome ſinecure place.

With this view he paid a viſit to an uncle who lived near Aberdeen, a man of great learning and in opulent circumſtances, in hopes that, by his intereſt, he might be ſettled in a poſt ſuitable to his merit: But how deluſive were his hopes! His uncle indeed received him with every mark of affection; but his fondneſs gradually cooled, and at the end of ſix months, he ordered him abruptly to leave his houſe, without having endeavoured to procure for him any ſettlement.

To a mind like Ferguſſon's, feelingly alive, ſuch treatment from ſo near a relation, to whom he had always behaved with becoming reſpect, muſt have been dreadfully galling. Stung with indignation, he returned to his mother's at Edinburgh; and as ſoon as he recovered from a ſevere illneſs, brought upon him by diſappointment and the fatigue of his journey, he compoſed two elegies; one on "The Decay of Friendſhip," and the other "Againſt Repining at Fortune," both occaſioned by his adventure in the North. How much he felt the daſhing of his hopes, is apparent from the following pathetic lines in the Decay of Friendſhip:

But, ah! theſe youthful ſportive hours are fled,
  Theſe ſcenes of jocund mirth are now no more;
No healing ſlumbers 'tend my humble bed,
  No friends condole the ſorrows of the poor.

And what avails the thoughts of former joy?
  What comfort bring they in the adverſe hour?
Can they the canker-worm of care deſtroy,
  Or brighten fortune's diſcontented lour?

So deſtitute was he at this period, that he ſubmitted to copy papers in the commiſſary clerk's office, we believe at ſo much the ſheet; but not liking the employment, and quarrelling with the commiſſary clerk depute, he ſoon left the office in diſguſt.

Hitherto he had lived rather in obſcurity; and happy had it been for him, if in that obſcurity he had been ſuffered to remain: happy had it been for him, had his converſation been leſs faſcinating, and his company leſs courted by the frolic and the gay. Poſſeſſing an inexhauſtible fund of wit, the beſt good nature, much modeſty, and great goodneſs of heart, he was viewed with affection by all to whom he was known; but his powers of ſong, and almoſt unrivalled talents for mimickry, led him oftener into the company of thoſe who wiſhed for him merely to enliven a ſocial hour, than of ſuch as by their virtue were inclined, and by their influence were able, to procure him a competent ſettlement for life. The conſequence of this was great laxity of manners. His moral principles indeed were never corrupted, nor, as we have reaſon to believe, his faith in revelation ſhaken; but there is no doubt but that, courted as he was by the ſyren voice of pleaſure, he yielded to many temptations, and in the hours of ebriety committed

Fergusson.

committed actions which, in his cooler moments, he reflected on with abhorrence.

His conſcience was indeed frequently rouſed. Being on a viſit to a friend at Haddington, and ſauntering one day near the church yard, he was accoſted by a clergyman, who ſeemed to be no ſtranger to the kind of life which he led. This judicious divine contrived to draw his attention to the ſhortneſs of time, the length of eternity, death and judgment, and the awful ſtate that awaits the wicked in an unſeen world; and the converſation made a deep impreſſion on his mind. It ſeemed, however, to be effaced from his memory by the diſſipation of Edinburgh, till it was recalled with double effect by the following accident:

In the room adjoining to that in which he ſlept was a ſtarling, which being ſeized one night by a cat that had found its way down the chimney, awaked Mr Ferguſſon by the moſt alarming ſcreams. Having learned the cauſe of the alarm, he began ſeriouſly to reflect how often he, an immortal and accountable being, had in the hour of intemperance ſet death at defiance, though it was thus terrible in reality even to an unaccountable and ſinleſs creature. This brought to his recollection the converſation of the clergyman, which, aided by the ſolemnity of midnight, wrought his mind up to a pitch of remorſe that almoſt bordered on frantic deſpair. Sleep now forſook his eyelids; and he roſe in the morning, not as he had formerly done, to mix again with the ſocial and the gay, but to be a recluſe from ſociety, and to allow the remembrance of his paſt follies to prey upon his vitals. All his vivacity now forſook him; thoſe lips which were formed to give delight, were cloſed as by the hand of death; and "on his countenance ſat horror plum'd."

From this ſtate of gloomy deſpondency, however, he began gradually to recover; and, except that a ſettled melancholy was viſible in his countenance, his health was completely reſtored, when one evening he fell and cut his head ſo dreadfully, that from the loſs of blood he became delirious. In this deplorable ſtate he continued for ſeveral months, till, being quite exhauſted by want of ſleep and conſtant ſpeaking, he expired on the 16th of October 1774. He was interred in the Canongate church yard, where his friends erected a monument to his memory, which has been ſince removed to make way for a larger and more elegant monument by his enthuſiaſtic admirer the late poet Burns.

Thus died Robert Ferguſſon, a young man of the brighteſt genius and of the beſt heart, who, had he joined prudence to his uncommon talents, muſt have riſen to great eminence in the republic of letters; but, as a late juvenile poet has obſerved of him——

> Complete alike in head and heart,
> But wanting in the prudent part,
> He prov'd a poet's lot.

Of his poems no general character can be given. The ſubjects of them are ſometimes uncommon and generally local or temporary. They are of courſe very unequal. But ſuch of them as are in the Scottiſh dialect have been univerſally admired by his countrymen; and when it is conſidered that they were compoſed amidſt a round of diſſipation, they will be allowed to furniſh complete evidence of his genius and his taſte.

Fermanagh || Fermentation.

FERMANAGH, a townſhip in Mifflin co. Pennſylvania.—*Morse*.

FERMAT (Peter), who was counſellor of the parliament of Toulouſe in France, flouriſhed in the 17th century, and died in 1663. He was a man of great talents, and a very general ſcholar; but being contemporary and intimately connected with Des Cartes, Merſenne, Torricelli, and Huygens, he was naturally led to devote much of his time to the mathematical ſciences. He was (ſays Dr Hutton) a firſt rate mathematician, and poſſeſſed the fineſt taſte for pure and genuine geometry, which he contributed greatly to improve, as well as algebra.

Fermat was author of, 1. A Method for the Quadrature of all ſorts of parabolas.—2. Another on Maximums and Minimums: which ſerves not only for the determination of plane and ſolid problems, but alſo for drawing tangents to curve lines, finding the centres of gravity in ſolids, and the reſolution of queſtions concerning numbers: in ſhort, a method very ſimilar to the fluxions of Newton.—3. An Introduction to Geometric Loci, plane and ſolid.—4. A Treatiſe on Spherical Tangencies: where he demonſtrates in the Solids, the ſame things as Vieta demonſtrated in planes.—5. A Reſtoration of Apollonius's two books on Plane Loci.—6. A General Method for the dimenſion of Curve Lines. Beſides a number of other ſmaller pieces and many letters to learned men; ſeveral of which are to be found in his *Opera Varia Mathematica*, printed at Toulouſe, in folio, 1679.

FERMENTATION is a chemical proceſs which has been already conſidered in the *Encyclopædia*, and will be again reſumed in this *Supplement* under the title *Animal and Vegetable* Substances. In this place we mean nothing more than to give ſuch directions, principally from Mr Richardſon of Hull, for the proper fermentation of malt liquors as have not been fully detailed in the article Brewing (*Encycl.*)

This author controverts, we do not think very ſucceſsfully, the concluſions drawn by Mr Henry from the experiments, of which the reader will find an account in the article Fermentation (*Encycl.*); but it is not his theory with which we are at preſent concerned, but his practice as that of an experienced and enlightened brewer. Having treated of *Worts*, and the proper method of boiling them, for which ſee Wort in this *Supplement*, and having given an hiſtorical view of the proceſs of fermentation, of which a pretty accurate abridgement is inſerted in the articles Brewing and Fermentation (*Encycl.*), he proceeds thus:

"The agency of air, in the buſineſs of fermentation, is very powerful; but as all fermentable ſubjects have an abundant ſupply, we are rather to provide for the egreſs of their own, than to ſuffer the admiſſion of the external air, by which a great number of the fine, volatile, oleaginous parts of the ſubject would be carried off, and a proportionate injury in flavour and ſpirituoſity ſuſtained. Hence ſuch a covering ſhould be provided for the gyle-tun as would barely allow the eſcape of the common air produced by the operation; whilſt the *gas*, or fixed air, from its greater denſity, reſting upon the ſurface of the beer the whole depth of the curb, prevents the action of the external air, and conſequently the eſcape of thoſe fine and valuable parts juſt mentioned.

"But towards the conclusion of vinous fermentation, this aerial covering begins to lose its efficacy; which points out the necessity of then getting the beer into casks as soon as possible, that the consequences may be prevented, of exposing so large a surface, liable to so copious an evaporation. Amongst these, a loss of spirituosity is not the least; for this evaporation is more and more spirituous as the action approaches the completion of vinous fermentation; and that once obtained, the loss becomes still more considerable, if still exposed to the air; whence it might be termed the distillation of Nature, in which she is so much superior to art, that the ethereal spirit rises pure and unmixed, whilst the highest rectification of the still produces at best but a compound of aqueous and spirituous parts.

"Nor is this entirely conjecture. Experience teaches us, that we cannot produce so strong a beer in summer, *ceteris paribus*, as in winter; the reason is, not because the action of fermentation does not realize so much spirit in warm weather, but because the fermenting liquor, after the perfection of vinosity, continues so long in a state of rarefaction, that the spirituous parts are dissipated in a much greater degree at that time than at any other, in a similar state of progression. And this doctrine of natural distillation seems to account for that increase of strength obtainable from long preservation, in well closed casks, and, more particularly so, in glass bottles; for Nature, in her efforts to bring about her grand purpose of resolving every compound into its first principles, keeps up a perpetual internal struggle, as well as an external evaporation; and if the latter be effectually prevented, the former must be productive of additional spirituosity, so long as the action keeps within the pale of vinous fermentation.

"In order to maintain a due regulation of the fermenting power, and to answer the several purposes of the operation, a scrupulous attention to the degree of heat at which the action commences, and a particular regard to the quality and quantity of the ferment employed, are indispensably necessary." The degree of heat must be ascertained by the thermometer, and regulated by experience: the quantity of yeast can be ascertained only by the intention of the artist; but of the quality of that substance we shall treat under Yeast in this *Supplement*.

FERRISBURGH, a township in Addison co. Vermont, on lake Champlain. It contains 481 inhabitants. Otter creek, Little Otter and Lewis's creeks fall into the lake here. The mouth of Otter creek lies in N. lat. 44. 11. 45. W. long. 73. 9. 47.—*Morse*.

FEZZAN is a kingdom in the interior of Africa, placed in the vast wilderness as an island in the ocean. The following account of it was given to Mr Lucas the African traveller by an old shereef, a native of Fezzan; and that account was confirmed by the governor of Mesurata, who had himself visited Fezzan, and who, having treated the traveller with great kindness, ought not to be suspected of having wantonly deceived him.

According to this account, Fezzan is situated to the south of Mesurata (see Mesurata in this *Suppl.*), and the traveller from the latter place to the former arrives in eight days at Wadan, where refreshments are procured for the caravan. From thence in five hours they reach the desart of Soudah, where no vegetable is seen to grow but the talk, a tree from which the lemon coloured wood is taken which forms handles for tools. The passage of the desart takes up some days, when the traveller finds a miserable village, producing nothing but dates, brackish water, and Indian corn; from this village a day's journey conducts to the town of Sebbah, where are the remains of an ancient castle, and other venerable ruins, and in four days more he reaches Mourzouk, the capital of Fezzan.

This city is situated on the banks of a small river, surrounded by a high wall for defence, and is distant from Mesurata 390 computed miles. Eastward of Mourzouk is the town of Queela, in which are the remains of ancient buildings; the size of the cisterns, and the construction of the vaulted caves, exhibit instances of ancient splendor. South of which place is Jermah, distinguished by numerous and majestic ruins, on which are many inscriptions. Tessouwa lies eastward, near which was a river which the shereef remembers, but is now overwhelmed in the moving sands. N. E. from Mourzouk, distant about 120 miles, is the large town of Temmisswa, where the caravans of pilgrims from Bornou and Nigritia, by way of Cairo to Mecca, provide their stores for the desart.

In the town or province of Mendrah is a large quantity of *trona*, a species of fossil alkali, that floats on the surface or settles on the banks of its spreading lakes, great quantity of which is sent to Tripoli, and shipped for Turkey, Tunis, and Morocco: at the latter place it is used as an ingredient in the red dye of the leather. Mendrah is about 60 miles south of Fezzan. The territory of Fezzan extends but little westward, being confined by barren mountains. The smaller towns of this kingdom are said to be about one hundred; these towns are chiefly inhabited by husbandmen and shepherds; in every town a market is regularly held; mutton and goat's flesh are sold by the quarter, usually from thirty-two to forty grains of gold, or from four to five shillings English. The flesh of camels is dearer, and divided into smaller parts.

The houses are of clay, with flat roofs composed of branches of trees, on which earth is laid; this is sufficient in a climate where it never rains. The heats in summer, from April to November, are intense, and the hot winds blow from the south-east, south, and south-west; with such violence as to threaten suffocation; when it changes to the west or north-west a reviving freshness ensues.

The dress of the inhabitants is like that of the Moors of Barbary, consisting of a large pair of trowsers, a shirt which hangs over the trowsers, a kind of waistcoat without sleeves, and a jacket with tight sleeves; over the jacket is a loose robe which reaches below the knee, a girdle of crimson, and a long cloth called a *barakon* or *albaicque*, like a highland plaid, is worn; stockings of leather, laced like half boots, and slippers; on the head a red cap and turban; sometimes over the whole they throw a long cloak with a hood, called a *burnoose*. In summer they throw off all but the shirt and the cap.

The people bear very high degrees of heat, but any cold affects them sensibly. Their diseases are chiefly of the inflammatory and putrid kind; the small pox is common. Their old women are their principal physicians. For pains in the head they cup and bleed; for those in the limbs, they bathe in the hot lakes. They

Fezzan.

have a multitude of noxious and loathsome animals; the air is crowded with mosquitos, and their persons are over-run with the vermin which affect the beggars of Europe.

In their persons they incline to the negro, of a deep swarthy complexion, with curly black hair; they are tall, but indolent, inactive, and weak. In their common intercourse, distinction of rank seems to be forgotten; rich and poor, master and man, converse, eat, and drink, together; they are, however, generous and hospitable.

An extensive plain composes the kingdom of Fezzan: the soil is generally a light sand, the springs are abundant, and few regions in Africa exhibit a richer vegetation. The land produces the talk, the white thorn, date trees, the olive and lime, apricot, pomegranate, and fig: Indian corn and barley are the favourite objects of cultivation, of wheat there is little raised. The tame animals are, the sheep, cow, goat, and camel; and the wild are, the ostrich, antelopes of various kinds, one of which is called the huadee, which when chased plunges with address from a precipice, and lights on its hams.

The food of the lower class consists of flour of Indian corn, seasoned with oil and fruit; those of superior rank eat wheat bread and flesh. Fezzan produces much salt; the water has in general a mineral taste, but the favourite beverage is a liquor from the date tree, which acquires, when fermented, an intoxicating strength. In religion they are rigid Mahomedans, but tolerant. Their government monarchical; their present king is descended from one of the shereefs of Taffilet, who about 400 years since obtained the crown. Till the present century the kingdom was independent, when the Bashaw of Tripoli conquered and made it tributary; the reigning sovereign has nearly thrown off this yoke. In Fezzan, the descendants of the prophet are highly privileged, their property and persons are inviolable; they are exempt from certain punishments. This class are in general either princes or merchants.

The revenue is composed of a tax on towns and villages, a tax on every camel load of goods (except provisions) which enters the capital, fines for offences, lands of persons dying without heirs, and a tax on gardens and date trees. Gold dust by weight is the chief medium of payment; but for convenience they are furnished with small papers of gold dust of different values, from two *xarbes* or one and a half upwards; for smaller articles corn or flour are used as a medium. One grain of gold is equal to 1½d. sterling. The Fezzan grain is the same as in England.

The justice of the sovereign is highly extolled; small offences are punished by the bastinado, and the punishments increase to fine, imprisonment, and death. Trusting to their natural defence, their towns are without guard, and they have no standing forces. The only war the shereef remembered was undertaken against a people inhabiting the mountains of Tibesti, which is separated from the people of Fezzan by a wide and sandy desart. These people are wild and savage, and had plundered a caravan belonging to the king, who sent an army of between 3 and 4000 men against and subdued them. The country of these people produces much senna. The vales of Tibesti are said to be fertile in corn and pasture for cattle, particularly camels. The people live in huts, and profess various religions, some the Mahomedan, others are attached to their ancient idolatry.

Fezzan ‖ Figurate.

The people of Fezzan carry on a considerable trade with Tripoli, Bornou, Nigritia, &c. At the end of October, when the heats are abated, the caravans depart from Mourzouk in small parties of ten or twelve, unless in time of war. They lay in provisions of dates, meal, and mutton salted, dried in the sun, and boiled in oil or fat. The merchants have agents in the chief towns, to whom they send the slaves they purchase. The caravans to Tripoli carry the *trona*, senna, gold and slaves brought from the southern countries; and in return bring back cutlery, woollen, silks, dollars, copper, and brass.

That to Bornou carries brass and copper, for the currency of the country, imperial dollars, and various manufactures, but of their own produce only a preparation of dates, and meal of Indian corn, and they take in return slaves, gold dust, and civet.

To Cashna, an empire in Nigritia, they carry cowries, brass to make rings and bracelets, horses, several kinds of manufactures, and the Gooroo nuts; and in return take gold dust, slaves, cotton cloth, dyed goats skins, hides, senna, and civet, for the countries south of the Niger, where also they convey sabre blades and Dutch knives, coral, brass beads, looking glasses, dollars, &c. and receive back gold dust, slaves, cotton cloths, goat skins, Gooroo nuts, cowries, and ivory.

A caravan of pilgrims sets out likewise in the autumn of every second and third year from Mourzouk, the capital of Fezzan, to Mecca. They proceed to Temessa, over the mountain of Ziltan, and thence to Sibbul, a place subject to Tripoli; and thence nearly in a line with the Mediterranean sea to Cairo, and thence to Mecca by the customary route.

As not one celestial observation has been taken to determine any latitude between Benin and Tripoli, all the positions are fixed by estimation, reckoning fifteen or sixteen miles for a day's journey. Mr Rennell places Mourzouk, the capital of Fezzan, in lat. 27°. 20', or 260 miles from Masurata.

FIDLERS *Elbow*, a bend of Wood creek, between the outlet of South bay and the mouth of the creek, at the northern end of lake Champlain, opposite the mouth of East bay. The mouth of Wood creek lies in N. lat. 43. 32. W. long. 73. 15. 12.—*Morse.*

FIGURATE NUMBERS are such as do or may represent some geometrical figure, such as a triangle, pentagon, or pyramid, &c. These numbers are treated of at great length by Maclaurin in his Fluxions; Simpson in his Algebra; and Malcolm in his Arithmetic; but the following account of them by Dr Hutton is as perspicuous as any that we have seen:

Figurate numbers are distinguished into orders, according to their place in the scale of their generation, being all produced one from another, viz. by adding continually the terms of any one, the successive sums are the terms of the next order, beginning from the first order, which is that of equal units 1, 1, 1, 1, &c.; then the 2d order consists of the successive sums of those of the 1st order, forming the arithmetical progression 1, 2, 3, 4, &c.; those of the 3d order are the successive sums of those of the 2d, and are the triangular numbers 1, 3, 6, 10, 15, &c.; those of the 4th order are the

Figurate Numbers.

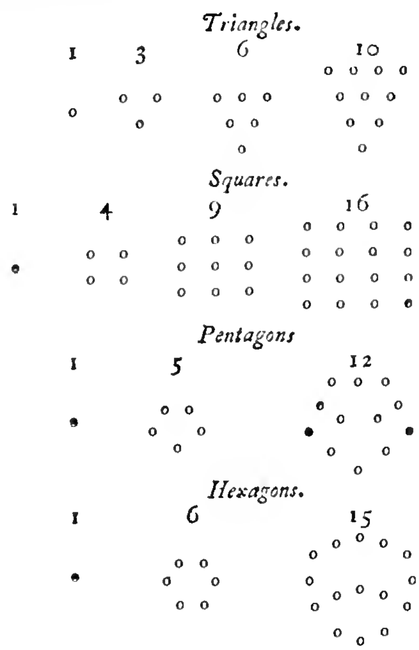
the successive sums of those of the 3d, and are the pyramidal numbers 1, 4, 10, 20, 35, &c.; and so on, as below:

Order.	*Name.*	*Numbers.*					
1.	Equals.	1,	1,	1,	1,	1,	&c.
2.	Arithmeticals,	1,	2,	3,	4,	5,	&c.
3.	Triangulars,	1,	3,	6,	10,	15,	&c.
4.	Pyramidals,	1,	4,	10,	20,	35,	&c.
5.	2d Pyramidals,	1,	5,	15,	35,	70,	&c.
6.	3d Pyramidals,	1,	6,	21,	56,	126,	&c.
7.	4th Pyramidals,	1,	7,	28,	84,	210,	&c.

The above are all considered as different sorts of triangular numbers, being formed from an arithmetical progression whose common difference is 1. But if that common difference be 2, the successive sums will be the series of square numbers: if it be 3, the series will be pentagonal numbers, or pentagons; if it be 4, the series will be hexagonal numbers, or hexagons; and so on. Thus:

Arithmeticals.	1st *Sums*, or *Polygons.*	2d *Sums*, or 2d *Polygons.*
1, 2, 3, 4,	Tri. 1, 3, 6, 10	1, 4, 10, 20
1, 3, 5, 7,	Sqrs. 1, 4, 9, 16	1, 5, 14, 30
1, 4, 7, 10,	Pent. 1, 5, 12, 22	1, 6, 18, 40
1, 5, 9, 13,	Hex. 1, 6, 15, 28	1, 7, 22, 50
&c.		

And the reason of the names triangles, squares, pentagons, hexagons, &c. is, that those numbers may be placed in the form of these regular figures or polygons, as here below:



But the figurate numbers of any order may also be found without computing those of the preceding orders; which is done by taking the successive products of as many of the terms of the arithmeticals 1, 2, 3, 4, 5, &c. in their natural order, as there are units in the number which denominates the order of figurates required, and dividing those products always by the first product. Thus the triangular numbers are found by dividing the products 1 × 2, 2 × 3, 3 × 4, 4 × 5, &c. each by the first prod. 1 × 2; the first pyramids by dividing the products 1 × 2 × 3, 2 × 3 × 4, 3 × 4 × 5, &c. by the first 1 × 2 × 3. And, in general, the figurate numbers of any order n, are found by substituting successively 1, 2, 3, 4, 5, &c. instead of x in this general expression $\frac{x \,.\, \overline{x+1} \,.\, \overline{x+2} \,.\, \overline{x+3} \,.\, \&c.}{1 \,.\, 2 \,.\, 3 \,.\, 4 \,.\, \&c.}$; where the factors in the numerator and denominator are supposed to be multiplied together, and to be continued till the number in each be less by 1 than that which expresses the order of the figurates required.

Filter.

FILTER (See *Encycl.*). It is well known that vessels made of a particular kind of porous stone are employed as filtering basins for freeing water, intended to be drunk, from various kinds of impurity. In sea voyages such filtering basins must be highly useful; and they are frequently found useful at land where no water can be had but from stagnant pools, or springs flowing through clay. The stone, however, of which they are made is not every where to be found; and therefore different persons have endeavoured to employ the art of the potter to supply their place.

In the year 1790 a patent was granted to a female potter, for her invention of the following composition for this purpose; viz. four equal parts, out of nine equal parts, of tobacco-pipe clay; and five equal parts, out of nine equal parts, of coarse sea, river, drift, or pit sand; these two materials, in the above proportions, are sufficient for the purpose of making small basins, and other vessels, to contain a quantity not exceeding one gallon of water, or other liquid. But the composition, when confined to these two materials, and in these proportions, often flies or cracks in the fire, if larger basins, or other vessels, are attempted to be made with it. She, therefore, in the second instance, composes her filtering basins of equal parts of tobacco-pipe clay and coarse sea, river, drift, or pit sand; in the third instance, of three equal parts, out of nine equal parts, of tobacco-pipe clay; one equal part, out of nine equal parts, of Stourbridge clay, or clay from the surface of coal-mines, or any other clay of the same quality; one equal part, out of nine equal parts, of Windsor, or other loam, of the same quality with Windsor loam; and four equal parts, out of nine equal parts, of coarse river, sea, drift, or pit sand. Or, in the fourth instance, of four equal parts, out of eight equal parts, of tobacco-pipe clay; three equal parts, out of eight equal parts, of coarse sea, river, drift, or pit sand; and one equal part, out of eight equal parts, of that burnt ground clay of which crucibles are made.

If the lady who invented, or pretends to have invented, these basins, have a right to her patent, far be it from us to wish our readers of any description to incroach upon it; but as the use of the materials of which her basins are made was known to potters before she was born, they may certainly compound these materials in proportions different from hers, without doing her any legal injury. As she varies her own proportions so much, we think it probable that some proportion differing a little from them all, may answer the purpose of filtering vessels equally well; and it is almost needless to add, that with this precaution any potter may make such vessels, for which he would undoubtedly have a great demand.

Filter.

A patent has likewife been granted to Mr Jofhua Collier of Southwark for a very ingenious contrivance for filtering and fweetening water, oil, and all other liquids. Of this contrivance, which combines the application of machinery with the antifeptic properties of charcoal (See CHEMISTRY N° 34. *Supplement*), we fhall give a detailed account.

Fifh oil is one of the liquids which he had it particularly in view to free from all its impurities in fmell, tafte, and colour; and the chemical procefs employed by him for this purpofe confifts in pouring a quantity of any fpecies of fifh oil, or a mixture of different forts of fifh oil, into any convenient veffel, which is to be heated to the temperature of 110 or 120 degrees of Fahrenheit's fcale, and then adding of cauftic mineral alkali, of the fpecific gravity commonly defcribed as 1.25, or of fuch ftrength that a phial containing 1000 grains of diftilled water will contain 1250 grains of thefe lees, a quantity equal to four parts of the 100 by weight of the quantity of oil; the mixture is then to be agitated, and left to ftand a fufficient time for the falts and fediments to fubfide; it is then drawn off into another veffel, containing a fufficient quantity of frefh burnt charcoal, finely powdered, or any other fubftance poffeffing antifeptic properties, in a powdered or divided ftate, with an addition of a fmall proportion of diluted fulphuric acid, fufficient only to decompofe the fmall quantity of faponaceous matter ftill fufpended in the oil, which appears by the oil becoming clear at the furface: the contents of this veffel are alfo agitated, and the coaly faline and aqueous particles left to fubfide; after which the oil is paffed through proper ftrainers, herein after defcribed, and is thereby rendered perfectly tranfparent and fit for ufe.

The principle of the improved ftrainers, or filtering machines, confifts in the means applied to combine hydroftatic preffure, which increafes according to the perpendicular height of the fluid, with the mode of filtering *per afcenfum*, thereby procuring the new and peculiar advantage that the fluid and its fediment take oppofite directions. A great advantage attending this invention is, that the dimenfions of the chamber in which the fediment is received, may be varied, while the filtering furface remains the fame. To adapt the machines not only to the purpofe of familes, work-houfes, hofpitals, public charities, the navy, or the merchant fervice, but alfo to all the purpofes of oil-men, of diftillers, of the laboratory, the brewery, &c. chambers of various capacities muft be provided for the fediment and precipitated matter. With refpect to the oil-trade, the fpace required is very great, efpecially for fpermaceti, or Brafil bottoms. In the various purpofes of the laboratory, no limits can be fixed, but all dimenfions will be occafionally required: in diftilleries and breweries they may be fmaller in proportion; and in that defigned for water and for domeftic ufe, a very fmall chamber will be fufficient. When water is to be fweetened, or freed from any putrid or noxious particles, it paffes, in its way to the filtering chamber, through an iron-box, or cylinder, containing charcoal finely powdered, or any other antifeptic fubftance infoluble in water, the water being forced into it by hydroftatic preffure, through a tube of any fufficient height. This box has two apertures to receive and deliver the fluid, and thefe are opened and clofed by cocks, or fcrews, or any other method ufed for fuch purpofes, and being affixed to the machine by other fcrews, may be eafily detached from the fame. Thus, whenever the charcoal begins to lofe its antifeptic properties, the box is removed and heated till it is red hot; by which means the foreign matter efcapes through the fmall apertures, after which the box is cooled, and the charcoal becomes fweet, pure, and equally fit for ufe as at firft, though the procefs be ever fo often repeated.

Filter

Another part of the invention confifts in filtering machines in the form of ftills, in which charcoal may be repeatedly burned after any fluid fubftances have paffed through it, for the purpofe of freeing them either from putrid or noxious particles, or of difcharging their colouring matter; which filtering ftills are fo contrived, that the fluid may pafs through in any quantity, without difplacing the charcoal: the part of the fluid remaining interfperfed among the charcoal, may be driven over by heat, and be employed for many inferior purpofes of the arts or manufactures. Laftly, the heat may be raifed fo as to purify the charcoal, as has been before defcribed in the machines for water. The flue of thofe ftills is fo conftructed that water may be employed to cool them without the lofs of time requifite for their gradually parting with their heat to the furrounding atmofphere, fo as to be fit for a fubfequent operation.

But it was not merely to the purifying of oils and various liquids that Mr Collier turned his attention. To his filtering apparatus are attached inftruments for afcertaining the comparative qualities of oils, which depend in part on the principle of their fpecific gravities; fpermaceti oil, contrafted with other fifh oils, being as 875 to 920. For this purpofe, a glafs veffel of any convenient fhape, is made ufe of, furnifhed with a bubble alfo of glafs, and a thermometer. If the oil is pure, this bubble finks, when the mercury rifes to a certain ftandard, by the application of the hand, or any other heat to the veffel containing the oil. If the fpermaceti oil is impure, the bubble will ftill float, though it is of the temperature required; and the degree of impure, or foreign matter, will be fhewn by the ftate of the thermometer at which the bubble finks.

To determine what tendency oils ufed for burning have to congeal in cold weather, a freezing mixture is put in a phial of thin glafs, or any other convenient veffel; into this a thermometer is immerfed, and a fingle drop of the oil, under experiment, fuffered to fall on the outfide of the veffel, where it immediately congeals; as the cold produced by the mixture gradually ceafes, it is eafy to obferve by the thermometer at what point of temperature the oil becomes fluid, and runs down the fide of the glafs.

A fhort defcription of this apparatus will make its principles plain to every reader. A (fig. 1.) is the ciftern, into which the water or other liquor to be filtered is put. B B is a tube opening into the bottom of the ciftern A, and bent along the bottom of the machine conveying the fluid into C C C the filtering chamber which is covered with leather bound down round its circular rim, and through which leather the water is percolated. D D, The bafon rifing above the level of the chamber and receiving the filtered liquor. E, The fpout by which it runs off into a pitcher or other veffel. F, Another fpout furnifhed with a Plate XXIII.

cock

cock to draw off the foul water from the chamber when necessary. G G G, The air tube, which begins above the level of the chamber, is covered with a button, which saves the leather from being cut, and has a small lateral aperture for the air to be carried off. This pipe passes along the bottom and up the side, and rising above the level of the water in the cistern, is there closed, except a small lateral aperture through which the air escapes. H, A guard or rim with cross bars put over the leather to keep it from being forced up by the water. It is fastened down by means of two notches on opposite sides of the guard, by which it locks into two staples rivetted into the bottom of the bason. I, the lid sliding down to cover the water from dust, and suspended at pleasure by means of K K, two springs on each tube for that purpose. L M N O, A cylindrical box containing charcoal, which is connected with the above by means of the tube P, and a continuation of the tube B. L M, The water tube B continued below the charcoal apparatus, so that the fluid may pass through the same into the cylinder, from whence it enters the chambers at P, so as to be filtered through the leather as before described. R R, Collars which may be unscrewed at pleasure, so as to detach the charcoal apparatus whenever the charcoal requires to be purified by heat. S S, Two cocks to direct the fluid through the charcoal cylinder or immediately into the filtering chamber.

Fig. 2. A, A tub or cistern, containing the oil to be filtered, and supplying a tube of sufficient height for the hydrostatic pressure to operate. B B, A main tube of wood, tin, leather, or cloth, to which any number of bags, of the size and shape of corn sacks, or any C C convenient size or shape may be connected. These are bound to D D D, straight double iron bars, furnished with a hinge at one end and a screw at the other, by opening which the bags may be emptied. F, A trough underneath, made to receive the filtered oil from the receivers E E E.

Fig. 3. A, A funnel cask or cistern, into which the fluid is put which passes down. B, A tube fitted into the same, through which it enters. C, An iron still, or still of any other substance capable of sustaining heat, full of finely powdered and sifted charcoal, through the head of which the fluid passes into any receiver. D, A fire place of any construction to drive over the fluid remaining interspersed among the charcoal, and also to purify the charcoal by an increase of temperature when required. E, A cock to let water into the flues to cool the apparatus for a subsequent operation.

FINDLEY, a township in Washington co. Pennsylvania.—*ib.*

FIRE. See that article *Encycl.* and Caloric and Combustion, *Chemistry Index* in this *Suppl.*

Extinction of FIRE is sometimes a matter of so much consequence, that every thing which promises to be effectual for that purpose is worthy of attention. In the nineteenth number of Mr Nicholson's Journal of Philosophy, Chemistry, and the Arts, we have the following composition for extinguishing fire, invented by M. Von Aken.

Burnt Alum - -	pounds	30
Green vitriol powdered - -		40
Cinabrese or red ochre in powder -		20
Potter's clay, or other clay, also powdered		200
Water, - - - - -		630

With 40 measures of this mixture an artificial fire was extinguished under the direction of the inventor by three persons, which would have required the labour of 20 men, and 1500 measures of common water. Sig. Fabbroni was commissioned to examine the value of this invention, and found, in his comparative trials with engines of equal power, worked by the same number of men, that the mixture extinguished the materials in combustion in one sixth part less time, and three eighths less of fluid than when common water was used. He observed, as might indeed have been imagined from the nature of the material, that the flame disappeared wherever the mixture fell, and that the saline, metallic, and earthy matters formed an impenetrable lute round the hot combustible matter, which prevented the access of the air, and consequently the renewal of the destructive process.

This recipe, Mr Nicholson informs us, is taken from the 85th N° of the Giornale Letterario di Napoli, in which it was inserted in the form of a letter from Sig. Fabbroni to Sig. D. Luigi Targioni of Naples; and the author of the letter estimates the price of the composition at about one halfpenny per pound.

The reason assigned by Mr Nicholson for giving this abridged account a place in his valuable work, will be admitted by him and the public as a sufficient reason for our adopting it into our's. It is, that such inventions are worthy of the attention of philosophers and economists, even though in the first applications they may prove less advantageous than their inventors may be disposed to think. It is scarcely probable that this practice in the large way, with an engine throwing upwards of 200 gallons (value about L. 3, 10s) each minute, would be thought of or adopted, or that a sufficient store of the materials would be kept in readiness; since at this rate the expenditure for an hour would demand provision to the amount of L. 210 sterling. But in country places the process, or some variation of it, might be applied with sufficient profit in the result, more especially if it be considered that common salt or alum, or such saline matter as can be had and mixed with the water, together with clay, chalk, or lime, ochreous earth or common mud, or even these last without any salt, may answer the purpose of the lute with more or less effect, and extinguish an accidental fire with much greater speed and certainty than clear water would do.

Fire-Balls are meteors, of which some account has been given in the *Encyclopædia*, as well as of various hypotheses which have been framed respecting their nature and their origin. Since that article was published, a new and very singular hypothesis has been framed by Professor Chladni of Wittenberg, who maintains it by arguments, which, however fanciful, are yet worthy of the reader's notice.*

He supposes, that fire balls, instead of being collections

* *Phil. Mag.* nos. 5 and 7.

Fire.

tions of the electrical fluid floating in the highest regions of our atmosphere, are masses of very dense matter formed in far distant parts of space, and subjected to similar laws with the planets and comets. He endeavours to prove, that their component parts must be dense and heavy; because their course shews, in so apparent a manner, the effects of gravity; and because their mass, though it distends to a monstrous size, retains sufficient consistency and weight to continue an exceedingly rapid movement through a very large space, without being decomposed or dissolved, notwithstanding the resistance of the atmosphere. It seems to him probable, that this substance is by the effect of fire reduced to a tough fluid condition; because its form appears sometimes round and sometimes elongated, and as its extending till it bursts, as well as the bursting itself, allows us to suppose a previous capability of extension by elastic fluidity. At any rate it appears to be certain, that such dense matter, at so great a height is not collected from particles to be found in our atmosphere, or can be thrown together into large masses by any power with which we are acquainted; that no power with which we are acquainted is able to give to such bodies so rapid a projectile force in a direction almost parallel to the horizon; that the matter does not rise upwards from the earth, but exists previously in the celestial regions, and must have been conveyed thence to our earth. In the opinion of Dr Chladni, the following is the only theory of this phenomenon that agrees with all the accounts hitherto given, which is not contrary to nature in any other respect, and which besides seems to be confirmed by various masses found on the spot where fire-balls fell.

As earthy, metallic, and other particles form the principal component parts of our planets, among which iron is the prevailing part, other planetary bodies may therefore consist of similar, or perhaps the same component parts, though combined and modified in a very different manner. There may also be dense matters accumulated in smaller masses, without being in immediate connection with the larger planetary bodies dispersed throughout infinite space; and which, being impelled either by some projecting power or attraction, continue to move until they approach the earth or some other body, when, being overcome by its attractive force, they immediately fall down. By their exceedingly great velocity, still increased by the attraction of the earth and the violent friction in the atmosphere, a strong electricity and heat must necessarily be excited; by which means they are reduced to a flaming and melted condition, and great quantities of vapour and different kinds of gases are thus disengaged, which distend the liquid mass to a monstrous size, till, by a still farther expansion of these elastic fluids, it must at length burst. Dr Chladni thinks also that the greater part of the *shooting stars*, as they are called, are nothing else than fire-balls, which differ only from the latter in this, that their peculiarly great velocity carries them past the earth at a greater distance, so that they are not so strongly attracted by it as to fall down; and therefore, in their passage through the high regions of the atmosphere, occasion only a transient electric flash, or actually take fire for a moment, and are again speedily extinguished, when they get to such a distance from the earth that the air becomes too much rarefied for the existence of fire.

The grounds on which Dr Chladni supports this opinion are various relations, well authenticated, of the motions of those meteors, and the phenomena which accompany their bursting. Besides those mentioned in the *Encyclopædia*, he lays a particular stress on the account which he received from *M. Baudin*, Professor of philosophy at Pau, of a remarkable fiery meteor seen in Gascony on the 24th of July, 1790. On the evening of that day M. Baudin was in the court of the castle of Mormes with a friend, the atmosphere being perfectly clear, when they suddenly found themselves surrounded by a whitish light, which obscured that of the full moon, then shining with great lustre. On looking upwards, they observed, almost in their zenith, a fire-ball of a larger diameter than the moon, and with a tail equal in length to five or six times the diameter of the body. The ball and the tail were of a pale white colour, except the point of the latter, which was almost as red as blood. The direction of this meteor was from south to north.

"Scarcely (says M. Baudin) had we looked at it for two seconds, when it divided itself into several portions of considerable size, which we saw fall in different directions, and almost with the same appearance as the bursting of a bomb. All these different fragments became extinguished in the air, and some of them, in falling, assumed that blood-red colour which I had observed in the point of the tail. It is not improbable that all the rest may have assumed the same colour; but I remarked only those which proceeded in a direction towards Mormes, and which were particularly exposed to my view.

"About two minutes and a half, or three minutes after, we heard a dreadful clap of thunder, or rather explosion, as if several large pieces of ordnance had been fired off together. The concussion of the atmosphere by this shock was so great, that we all thought an earthquake had taken place. The windows shook in their frames, and some of them, which probably were laid to, and not closely shut, were thrown open. We were informed next day, that in some of the houses at Houga, a small town about half a mile distant from Mormes, the kitchen utensils were thrown from the shelves; so that the people concluded there had been an earthquake. But as no movement was observed in the ground below our feet, I am inclined to think that all these effects were produced merely by the violent concussion of the atmosphere.

"We proceeded into the garden while the noise still continued and appeared to be in a perpendicular direction above us. Sometime after, when it had ceased, we heard a hollow noise, which seemed to roll along the chain of the Pyrenees in echoes, for the distance of fifteen miles. It continued about four minutes, becoming gradually more remote, and always weaker; and at the same time we perceived a strong smell of sulphur.

"While we were endeavouring to point out to some persons present the place where the meteor had divided itself, we observed a small whitish cloud, which arose perhaps from the vapour of it, and which concealed from us the three stars of the Great Bear, lying in the middle of those forming the semicircle. With some difficulty,

difficulty, however, we could at laft diftinguifh thefe ftars again behind the thin cloud. There arofe, at the fame time, a frefh gentle breeze.

"From the time that elapfed between the burfting of the ball, and the explofion which followed, I was inclined to think, that the meteor was at the height of at leaft feven or eight miles, and that it fell four miles to the north of Mormes. The latter part of my conjecture was foon confirmed by an account which we received, that a great many ftones had fallen from the atmofphere at Juliac, and in the neighbourhood of Barbotan. One of thefe places lies at the diftance of about four miles to the north of Mormes, and the other at about the diftance of five to the north-northweft."

M. de Carrits Barbotan, the friend who was with the Profeffor in the court and garden of Mormes when the meteor firft attracted their attention, was at Juliac two days afterwards, and confirmed to him the truth of this circumftance. It appeared, likewife from the account of feveral intelligent perfons, highly worthy of credit, that the meteor burft at a little diftance from Juliac, and that the ftones which fell were found lying in a fpace almoft circular, about two miles in diameter. They were of various fizes. Some were *feen to fall*, which, when found, weighed 18 or 20 pounds, and which had funk into the earth from two to three feet. M. de C. Barbotan tranfmitted one weighing 18 pounds to the academy of fciences at Paris; and M. Baudin was told, that fome were found which weighed even 50 pounds. He examined a fmall one, and found it very heavy in proportion to its fize: it was black on the outfide; of a greyifh colour in the infide, and interfperfed with a number of fmall fhining metallic particles. On ftriking it with a piece of fteel, it produced a few fmall dark red fparks, not very lively. A mineralogift, to whom a like piece of ftone from the fame meteor was fhewn at Paris, defcribed it as a kind of grey flag mixed with calcareous fpar, the furface of which exhibited vitrified blackifh calx of iron. The Profeffor was told alfo, that fome ftones were found totally vitrified.

Such (fays Dr Chladni) is the account given by Baudin of this meteor; the phenomena of which he endeavours to explain from accumulations in the upper parts of the atmofphere.

According to all the obfervations hitherto made with any accuracy on fire-balls, the height at which they were firft perceived was always very confiderable, and by comparing the angles under which they were feen from different points, often 19 German miles, and even more; their velocity, for the moft part, feveral miles in a fecond; and their fize always very great, often a quarter of a mile, and even more, in diameter. They were all feen to fall moftly in an oblique direction; not one of them ever proceeded upwards. All of them have appeared under the form of a globular mafs, fometimes a little extended in length and highly luminous; having behind it a tail, which, according to every appearance, was compofed of flames and fmoke. All of them burft after they were feen to move through a large fpace, fometimes over feveral diftricts, with an explofion which fhook every thing around. In every inftance where there has been an opportunity of obferving the fragments that fell after they burft, and which fometimes have funk to the depth of feveral feet into the earth, they were found to confift of fcorious maffes, which contained iron in a metallic or calcined ftate, pure, or elfe mixed with different kinds of earth and fulphur. All the ancient and modern accounts, written partly by naturalifts, and partly by others, are fo effentially fimilar, that the one feems to be only a repetition of the other. This conformity in accounts, the authors of which knew nothing of thofe given by others, and who could have no intereft in fabricating fimilar tales, can fcarcely have arifen from accident or fiction, and gives to the related facts, however inexplicable many of them may feem, every degree of credibility.

In the third volume of Pallas's Travels, we have an account of a mafs of iron difcovered by him in Siberia, which Dr Chladni confiders as having been undoubtedly a fire-ball, or the fragment of a fire-ball. This problematical mafs was found between Krafnojarfk and Abekanfk in the high flate mountains, quite open and uncovered. It weighed 1600 pounds; had a very irregular and fomewhat compreffed figure like a rough granite; was covered externally with a ferruginous kind of cruft; and the infide confifted of malleable iron, brittle when heated, porous like a large fea fponge, and having its interftices filled with a brittle hard vitrified fubftance of an amber yellow colour. This texture and the vitrified fubftance appeared uniformly throughout the whole mafs, and without any traces of flag or artificial fire.

Dr Chladni fhews with a great deal of ingenuity, that this mafs neither originated by the wet method, nor could have been produced by art, the burning of a foreft, by lightning, or by a volcanic eruption. It appears to him, therefore, in the higheft degree probable, that it is of the fame nature with fire-balls, or, as they have fometimes been called, *flying dragons*. The Tartars, as we are informed by Pallas, confidered this mafs as a facred relict which had dropped down from heaven; and this circumftance Dr Chladni confiders as no flight confirmation of his opinion, which he farther fupports by the following reafonings:

"1. As fire-balls confift of denfe and heavy fubftances, which, by their exceedingly quick movement, and the friction thence excited by the atmofphere, become electric, are reduced to a ftate of ignition, and melted by the heat, fo that they extend to a great fize, and burft; it thence follows, that in places where fragments, produced by the burfting of a fire-ball, have been found, fubftances endowed with all thefe properties muft alfo have been found. Iron, however, the principal component part of all the maffes hitherto found (and he fpeaks of many befides that of Pallas), poffeffes all thefe properties in a very eminent degree. The weight and toughnefs of the principal component parts of fire-balls, which muft be very confiderable, fince, with the greateft poffible diftention, they retain confiftence enough to proceed with the utmoft velocity through fuch an immenfe fpace without decompofition of their mafs, and without their progrefs being obftructed by the refiftance of the air, agree perfectly well with melted iron; their dazzling white light has by many obfervers been compared to that of melted iron; iron alfo exhibits the fame appearances of flaming, fmoking, and throwing out fparks, and all thefe phenomena are moft beautiful when

Fire.

when they take place in vital air. Of the extenſion by elaſtic fluids expanded by the heat, and of the contraction which follows from cold, traces may be diſcovered in the internal ſpongy nature of the iron maſſes which have been found, and in the globular depreſſions of the exterior hard cruſt; the latter of which gives us reaſon to ſuppoſe, that in theſe places there have been air-bubbles, which, on cooling, ſunk down. The mixture of ſulphur found in various maſſes, agrees alſo exceedingly well with the phenomena of fire-balls, and eſpecially with the great inflammability of ſulphur in very thin impure air; for it is well known, that ſulphur in an air-pump will take fire in air, in which few other bodies could do the ſame. In regard to thoſe maſſes in which no ſulphur was found, this may have ariſen from the ſulphur eſcaping in vapour, ſince ſome time after the appearance of fire-balls a ſtrong ſmell of ſulphur has been perceived. The brittleneſs of the Siberian iron maſs when heated, may ariſe from ſome ſmall remains of ſulphur, which may perhaps be the cauſe of the facility with which fragments of this maſs, as well as of another found at Aix-la-Chapelle, could be roaſted.

"2. The whole texture of the maſſes betrayed evident ſigns of fuſion. This, however, cannot have been occaſioned by any common, natural, or artificial fire; and particularly for this reaſon, becauſe iron ſo malleable is not fuſible in ſuch fire, and when it is fuſed with the addition of inflammable matters, loſes its malleability, and becomes like common raw iron. The vitrified ſubſtance in the Siberian maſs is equally incapable of being fuſed in a common fire. The fire, then, muſt have been much ſtronger than that produced by the common, natural, and artificial means; or the fuſion muſt have been effected by the force of exceedingly ſtrong electricity; or perhaps both cauſes may have been combined together.

"3. It is totally incomprehenſible how, on the high ſlate mountains, where the Siberian maſs was found, at a conſiderable diſtance from the iron mines; in the chalky ſoil of the extenſive plains of America, where for a hundred miles around there are no iron mines, and not even ſo much as a ſtone to be found; and at Aix-la-Chapelle, where, as far as the author knows, there are no iron works—ſo many ferruginous particles could be collected in a ſmall ſpace as would be neceſſary to form maſſes of 1600, 15,000, and 17,000, up to 33,600 pounds. This circumſtance ſhews, that theſe maſſes could as little have been fuſed by lightning as by the burning of a foreſt or of foſſile coal. Theſe maſſes were found quite expoſed and uncovered, and not at any depth in the earth, where we can much more readily admit ſuch an accumulation of ferruginous particles to have been melted by the effects of lightning.

"Should it be aſked, how ſuch maſſes originated, or by what means they were brought into ſuch an inſulated poſition? this queſtion would be the ſame as if it were aſked how the planets originated. Whatever hypotheſes we may form, we muſt either admit that the planets, if we except the many revolutions which they may have undergone, either on or near their ſurface, have always been ſince their firſt formation, and ever will be the ſame; or that nature, acting on created matter, poſſeſſes the power to produce worlds and whole ſyſtems to deſtroy them, and from their materials to form new ones. For the latter opinion there are, indeed, more grounds than for the former, as alternations of deſtruction and creation are exhibited by all organiſed and unorganiſed bodies on our earth, which gives us reaſon to ſuſpect that nature, to which greatneſs and ſmallneſs, conſidered in general, are merely relative terms, can produce more effects of the ſame kind on a larger ſcale. But many variations have been obſerved on diſtant bodies, which, in ſome meaſure, render the laſt opinion probable. For example, the appearing and total diſappearing of certain ſtars, when they do not depend upon periodical changes. If we now admit that planetary bodies have ſtarted into exiſtence, we cannot ſuppoſe that ſuch an event can have otherwiſe taken place, than by conjecturing that either particles of matter, which were before diſperſed through infinite ſpace in a more ſoft and chaotic condition, have united together in large maſſes by the power of attraction; or that new planetary bodies have been formed from the fragments of much larger ones that have been broken to pieces, either perhaps by ſome external ſhock, or by an internal exploſion. Let whichever of theſe hypotheſes be the trueſt, it is not improbable, or at leaſt not contrary to nature, if we ſuppoſe that a large quantity of ſuch material particles, either on account of their too great diſtance, or becauſe prevented by a ſtronger movement in another direction, may not have united themſelves to the larger accumulating maſs of a new world; but have remained inſulated, and, impelled by ſome ſhock, have continued their courſe through infinite ſpace, until they approached ſo near to ſome planet, as to be within the ſphere of its attraction, and then by falling down to occaſion the phenomena before mentioned."

Whether Chladni be a philoſopher of the French ſchool we know not; but ſome parts of his theory tend ſtrongly towards materialiſm; and the arguments by which he attempts to prop thoſe parts are peculiarly weak. When he talks of *Nature* producing worlds, he either ſubſtitutes Nature for Nature's God, or utters jargon which has no meaning. In what ſenſe the word Nature is uſed by every philoſopher of a ſound mind, we have elſewhere been at ſome pains to ſhew (ſee River, n° 116, *Encycl.*); but how abſurd would it be to ſay, that the ſyſtem of general laws, by which the Author and Governor of the univerſe connects together its various parts, and regulates all their operations, poſſeſſes, independently of him, the "power to produce worlds and whole ſyſtems, to deſtroy them, and from their materials to form new ones!"

As Chladni admits, or talks as if he admitted, the creation of matter, it would be wrong to impute to him this abſurdity; but if by *Nature* he means God, and he can conſiſtently mean nothing elſe, we beg leave to affirm, that it is *directly contrary* to every notion which we can form of Nature in *this ſenſe*, "to ſuppoſe that a large quantity of material particles, either on account of their *diſtance*, or becauſe prevented by a *ſtronger movement* in another direction, have not united themſelves to the larger accumulating maſs of a new world, but remained inſulated, and impelled by ſome ſhock, have continued their courſe through infinite ſpace, &c." Is there any diſtance to which God cannot reach, or any movement ſo ſtrong as to reſiſt his power? Our author's language is indeed confuſed, and probably his

ideas

ideas were not very clear. When he ſpeaks of the particles of matter being at firſt diſperſed through infinite ſpace, and afterwards united by the power of attraction, he revives the queſtion which was long ago diſcuſſed between Newton and Bentley, and diſcuſſed in ſuch a manner as ſhould have ſilenced for ever the bablings of thoſe who form worlds by attraction.

"The hypotheſis (ſays Newton) of matter's being at firſt evenly ſpread through the heavens, is, in my opinion, inconſiſtent with the hypotheſis of innate gravity without a ſupernatural power to reconcile them; and therefore infers a Deity. For if there be innate gravity, it is impoſſible now for the matter of the earth, and all the planets and ſtars, to fly up from them, and become evenly ſpread through all the heavens, without a ſupernatural power; and certainly that which can never be hereafter without a ſupernatural power, could never be heretofore without the ſame power". Dr Chladni, indeed, does not ſay that his particles of matter were *evenly* diſperſed through infinite ſpace; but ſuch muſt be his meaning, if he has any meaning: for matter *unevenly* diſperſed muſt, by an innate attraction, be united as ſoon as it exiſts, and ſo united as not to leave ſmall fragments of it to wander, we know not why, through the trackleſs void. Turn matter on all ſides, make it eternal or of late production, finite or infinite, there can be no regular ſyſtem produced but by a voluntary and meaning agent; and therefore, if it be true that fire-balls are maſſes of denſe matter, coeval with the planetary ſyſtem, exiſting in the celeſtial regions, and thence conveyed to our earth, they muſt have been formed, and their motions impreſſed upon them, by the Author of Nature for ſome wiſe purpoſe, though by us that purpoſe may never be diſcovered. One thing ſeems pretty clear, that wherever they may be formed, the phenomena attending their burſting, account ſufficiently for the notions of thunderbolts which have been generally entertained in all ages, and in every country.

Greek-Fire (ſee *Wild-Fire, Encycl.*). In the ſecond volume of Mr Nicholſon's Philoſophical Journal, we have the following receipt for making this compoſition, taken from ſome manuſcripts of Leonard de Vinci, who flouriſhed in the end of the fifteenth and beginning of the ſixteenth centuries, and who appears to have advanced far before his contemporaries in phyſical ſcience. Take the charcoal of willow, nitre, brandy, reſin, ſulphur, pitch, and camphor. Mix the whole well together over the fire. Plunge a woollen cord in the mixture, and form it into balls, which may afterwards be provided with ſpikes. Theſe balls, being ſet on fire, are thrown into the enemy's veſſels. It is called the Greek fire, and is a ſingular compoſition, for it burns even upon the water. Callinicus the architect taught this compoſition to the Romans (of Conſtantinople), who derived great advantage from it, particularly under the emperor Leo, when the Orientals attacked Conſtantinople. A great number of their veſſels were burned by means of this compoſition.

The compoſition of the Greek fire thus given by Vinci is found in nearly the ſame words in ſome of the writings of Baptiſta Porta; whence it appears that both authors derived their information from the ſame ſource. A compoſition which burnt without acceſs to the atmoſphere could not fail to fill the minds of our forefathers with wonder; but the modern diſcoveries in chemiſtry have diſcloſed the ſecret, by ſhewing, that the combuſtion is carried on by means of the oxygen contained in the nitre.

Raſant or *Razant Fire*, is a fire from the artillery and ſmall arms, directed parallel to the horizon, or to thoſe parts of the works of a place that are defended.

Running Fire is when ranks of men fire one after another; or when the lines of an army are drawn out to fire on account of a victory; in which caſe each ſquadron or battalion takes the fire from that on its right, from the right of the firſt line to the left, and from the left to the right of the ſecond line, &c.

FISHERSFIELD, a townſhip in Hillſborough co. New-Hampſhire, incorporated in 1763, containing 331 inhabitants. Sunapee pond lies partly here, and in the townſhip of Wendel. It is about 16 miles eaſterly of Charleſtown.—*Morſe.*

FISHER'*s Iſland*, in Long-Iſland ſound, lies oppoſite to Groton in Connecticut, is about 10 miles in length and 2 in breadth, having a light ſoil, favorable for raiſing ſheep. It produces alſo wheat and other grain. It is annexed to the townſhip of Southhold, in Suffolk co. on Long-Iſland.—*ib.*

FISHING, the art of catching fiſh. See Angling, Fishery, and Fishing, &c. *Encycl.*

Chineſe Fishing. We venture to give this appellation to ſome very ingenious contrivances of the people of China for catching in their lakes, not only fiſh, but water-fowl. For the purpoſe of catching fiſh they have trained a ſpecies of pelican, reſembling the common corvorant, which they call the *Leu-tze*, or fiſhing bird. It is brown, with a white throat, the body whitiſh beneath, and ſpotted with brown; the tail is rounded, the irrides blue, and the bill yellow. Sir George Staunton, who, when the embaſſy was proceeding on the ſouthern branch of the great canal, ſaw thoſe birds employed, tells us, that on a large lake, cloſe to the eaſt ſide of the canal, are thouſands of ſmall boats and rafts, built entirely for this ſpecies of fiſhery. On each boat or raft are ten or a dozen birds, which, at a ſignal from the owner, plunge into the water; and it is aſtoniſhing to ſee the enormous ſize of fiſh with which they return, graſped within their bills. They appeared to be ſo well trained, that it did not require either ring or cord about their throats to prevent them from ſwallowing any portion of their prey, except what their maſter was pleaſed to return to them for encouragement and food. The boat uſed by theſe fiſhermen is of a remarkable light make, and is often carried to the lake, together with the fiſhing birds, by the men who are there to be ſupported by it.

The ſame author ſaw the fiſhermen buſy on the great lake Wee-chaung-hee; and he gives the following account of a very ſingular method practiſed by them for catching the fiſh of the lake without the aid of birds, of net, or of hooks.

To one ſide of a boat a flat board, painted white, is fixed, at an angle of about 45 degrees, the edge inclining towards the water. On moonlight nights the boat is ſo placed that the painted board is turned to the moon, from whence the rays of light ſtriking on the whitened ſurface, give to it the appearance of moving water; on which the fiſh being tempted to leap as on their element, the boatman raiſing with a ſtring the board, turn the fiſh into the boat.

Water-fowl are much sought after by the Chinese, and are taken upon the same lake by the following ingenious device. Empty jars or gourds are suffered to float about upon the water, that such objects may become familiar to the birds. The fisherman then wades into the lake with one of those empty vessels upon his head, and walks gently towards a bird; and lifting up his arm, draws it down below the surface of the water without any disturbance or giving alarm to the rest, several of whom he treats in the same manner, until he fills the bag he had brought to hold his prey. The contrivance itself is not so singular, as it is that the same exactly should have occurred in the new continent, as Ulloa asserts, to the natives of Carthagena, upon the lake Cienega de Tesias.

FISHING *Bay*, in Maryland, lies on the E. side of Chesapeak bay, partly in Dorchester and Somerset counties. It receives several rivers from each county, the chief of which are Wicomico, Nanticoke; also Transquaking and Blackwater creeks. The entrance into this large bay lies between Goldsborough and Devil's islands.—*Morse.*

Fishing *Bay*, on the S. side of lake Ontario, is about 37 miles E. of Fort Niagara.—*ib.*

FISHING-CREEK, a township on Susquehanna river, in Pennsylvania.—*ib.*

FISHKILL, a post town in Dutchess co. New-York, 5 miles E. of Hudson river, on Fishkill or creek, at the foot of the Highlands, which rise S. of it; containing about 30 houses, a church for Episcopalians, and one for Low Dutch. The township is very extensive, and contained, in 1790, 5941 inhabitants, of whom 601 were slaves. It lies 14 miles S. by E. of Poughkeepsie, opposite Newburgh, and 66 N. of New-York city. There are a few houses only at the Landing, on the margin of the river.—*ib.*

Fish *Kill*, or *Creek*, on which the town above described stands, and from which it derives its name, is small, and empties into Hudson river, about a mile below the Landing, and nearly opposite New-Windsor.—*ib.*

Also, the name of a small stream which runs S. W. into Oneida lake.

Likewise, a stream which rises from Saratoga lake, and runs 6 miles easterly to the Hudson. Its mouth is opposite Batten kill, 2 miles above Saratoga town; and on the N. side of which Gen. Burgoyne's army laid down their arms as prisoners.—*ib.*

FISTULA Lachrymalis is a disease which, in all its stages, has been treated of in the article Surgery, chap. xiv. *Encycl.* A work, however, has been lately published by James Ware surgeon, in which there is the description of an operation for its cure considerably different from that most commonly used, and which, while it is simple, the author's experience has ascertained to be successful.

In the cure of this disease, which is very troublesome, and not very uncommon, it is a well known practice to insert a metallic tube in the nasal duct of the lachrymal canal: but the advantage derived from this operation is not at all times lasting. Among other causes of failure, Mr Ware notices the lodgment of inspissated mucus in the cavity of the tube. To remedy this defect, he recommends the following operation.

" If the disease has not occasioned an aperture in the lachrymal sac, or if this aperture be not situated in a right line with the longitudinal direction of the nasal duct, a puncture should be made into the sac, at a small distance from the internal juncture of the palpebræ, and nearly in a line drawn horizontally from this juncture towards the nose with a spear-pointed lancet. The blunt end of a silver probe, of a size rather smaller than the probes that are commonly used by surgeons, should then be introduced through the wound, and gently, but steadily, pushed on in the direction of the nasal duct, with a force sufficient to overcome the obstruction in this canal, and until there is reason to believe that it has freely entered into the cavity of the nose. The position of the probe, when thus introduced, will be nearly perpendicular; its side will touch the upper edge of the orbit; and the space between its bulbous end in the nose and the wound in the skin will usually be found, in a full-grown person, to be about an inch and a quarter, or an inch and three-eighths. The probe is then to be withdrawn, and a silver style, of a size nearly similar to that of the probe, but rather smaller, about an inch and three-eighths in length, with a flat head, like that of a nail, but placed obliquely, that it may sit close on the skin, is to be introduced through the duct, in place of the probe, and to be left constantly in it. For the first day or two after the style has been introduced, it is sometimes advisable to wash the eye with a weak saturnine lotion, in order to obviate any tendency to inflammation which may have been excited by the operation; but this in general is so slight, that our author has rarely had occasion to use any application to remove it. The style should be withdrawn once every day for about a week, and afterwards every second or third day. Some warm water should each time be injected through the duct into the nose, and the instrument be afterwards replaced in the same manner as before. Mr Ware formerly used to cover the head of the style with a piece of diachylon plaster spread on black silk, but has of late obviated the necessity for applying any plaster by blackening the head of the style with sealing-wax.

" The effect (says he) produced by the style, when introduced in the way above mentioned, at first gave me much surprise. It was employed with a view similar to that with which Mr Pott recommends the introduction of a bougie; viz. to open and dilate the nasal duct, and thus to establish a passage, through which the tears might afterwards be conveyed from the eye to the nose. I expected, however, that whilst the style continued in the duct the obstruction would remain, and of course that the watering of the eye, and the weakness of the sight, would prove as troublesome as they had been before the instrument was introduced. I did not imagine that any essential benefit could result from the operation until the style was removed, and the passage thereby opened. It was an agreeable disappointment to me to find that the amendment was much more expeditious. The watering of the eye almost wholly ceased as soon as the style was introduced; and in proportion as the patient amended in this respect, his sight also became more strong and useful. The style, therefore, seems to act in a twofold capacity: first, it dilates the obstructed passage; and then, by an attraction somewhat similar to that of a capillary tube, it guides the tears through the duct into the nose.

" The

"The wound that I usually make into the sac, if the suppurative process has not formed a suitable aperture in this part, is no larger than is just sufficient to admit the end of the probe or style; and this, in general, in a little time, becomes a fistulous orifice, through which the style is passed without occasioning the smallest degree of pain. The accumulation of matter in the lachrymal sac, which, previous to the operation, is often copious, usually abates soon after the operation has been performed; and, in about a week or ten days, the treatment of the case becomes so easy, that the patient himself, or some friend or servant who is constantly with him, is fully competent to do the whole that is necessary. It consists solely in withdrawing the style two or three times in the week, occasionally injecting some warm water, and then replacing the instrument in the same way in which it was done before.

"It is not easy to ascertain the exact length of time that the style should be continued in the duct. Some have worn it many years, and, not finding any inconvenience from the instrument, are still afraid and unwilling to part from it. Others, on the contrary, have disused it at the end of about a month or six weeks, and have not had the smallest return of the obstruction afterwards."

The author relates so many successful cases of this operation, that we thought it our duty to record his method in this Supplementary volume of our general repository of arts and sciences; for a successful practice, as well in surgery as in physic, must rest on the basis of experience.

FITCHBURGH, a post town of Massachusetts, Worcester co. 23 miles N. of Worcester, 24 from Concord, and 42 N. W. of Boston. It has 1151 inhabitants.—*Morse.*

FITZWILLIAM, a township in Cheshire co. New-Hampshire, about 16 miles E. of Connecticut river, and separated from Royalston in Worcester co. Massachusetts, by the state line. It was incorporated in 1773, and contains 1038 inhabitants.—*ib.*

Oblique or Second FLANK, or *Flank of the Curtain*, is that part of the curtain from whence the face of the opposite bastion can be seen, being contained between the lines rasant and fichant, or the greater and less lines of defence; or the part of the curtain between the flank and the point where the fichant line of defence terminates.

Covered, Low or *Retired Flank*, is the platform of the casemate which lies hid in the bastion, and is otherwise called the *orillon*.

Fichant Flank, is that from whence a cannon playing, fires directly on the face of the opposite bastion.

Rasant or *Razant Flank*, is the point from whence the line of defence begins, from the conjunction of which with the curtain the shot only raseth the face of the next bastion, which happens when the face cannot be discovered but from the flank alone.

FLATBUSH, the chief town of King's co. Long-Island, New-York. It is a pleasant and healthy town, situated on a small bay which opens E. from New-York harbor, and is 5 miles S. by E. from New-York city. It contains a number of dwelling-houses, mostly in one street; many of which are elegant and commodious. The inhabitants are chiefly of Dutch extraction. It contains 941 inhabitants, of whom 107 are qualified electors, and 378 are slaves. The productions are various kinds of fruit, vegetables, grain, &c. which find a ready market in the metropolis. The land lies low; and in summer the whole township appears like an extensive garden. The public buildings are a Dutch church, a court-house, and an academy, called Erasmus Hall, the most flourishing of all the academies in the state. It is in a pleasant and healthful situation, 4 miles from Brookline ferry.

A bloody battle was fought near this town on the 27 August, 1776, when the Americans were defeated by the British with great loss. The remains of the American army retreated to New-York under the cover of a thick fog.—*Morse.*

FLATLANDS, a small township in Kings co. Long-Island, distant from New-York city 6 or 7 miles. It contains 423 inhabitants, of whom 44 are qualified to be electors, and 137 are slaves.—*ib.*

FLAT *Rock*, is an expansive, clear, flat rock, but a little above the surface of the ground, and near the banks of a delightful rivulet of excellent water, which is one of the head branches of Great Ogeechee river, in Georgia. This is a common rendezvous or camping place for traders and Indians.—*ib.*

FLATTERY, Cape, so named by captain Cook, on account of its promising at a distance what it denied on a nearer approach. Lat. 48. 15. long. 235. 30. E. This cape, captain Ingraham of Boston, found to be the S. side of the entrance of the straits of Juan de Fuca. N. lat. 48 25. W. long. 124. 52.—*ib.*

FLEMINGTON, a small post town of New-Jersey, in Hunterdon co. lies about 6 miles N. eastward of Amwell on Delaware river, 23 N. N. W. of Trenton, 9 S. of Pittstown, and 53 N. E. by N. of Philadelphia. It contains about a dozen compact houses.—*ib.*

FLETCHER, a township in Franklin co. Vermont, containing only 47 inhabitants. It has Cambridge on the S. E. and Georgia W.—*ib.*

FLIE or Fly, that part of the mariner's compass on which the thirty-two points of the wind are drawn, and over which the needle is placed, and fastened underneath.

FLINT *River*, a considerable river of Georgia, which rises in the country of the Creek Indians, and running a S. and thence a S. W. course, joins the Appalachicola, at its entrance into Florida. The Flint is about 30 rods wide, and from 12 to 15 feet deep in summer, and has a gentle current. The territory lying on this river, especially on the upper part of it, presents every appearance of a delightful and fruitful region in some future day; it being a rich soil, and exceedingly well situated for every branch of agriculture, and offers an uninterrupted navigation to the bay of Mexico, and Atlantic ocean, and thence to the West-India islands and over the whole world. There are a number of villages of Creek Indians on this river. —*Morse.*

Flint, a small river, about 28 miles long, in the Genessee country, in New-York, which runs N. N. E. into Canandarqua creek.—*ib.*

FLINTSTON, a plantation in Cumberland co. Maine, having 180 inhabitants. It has one eminence in it called Saddle-Back mountain, but the country in general

general is level enough for cultivation. One half of it is covered with pine and white oak.—*ib.*

FLOATING Bodies are ſuch as ſwim on the ſurface of a fluid, of which the moſt important are ſhips and all kinds of veſſels employed in war and in commerce. Every ſeaman knows of how much conſequence it is to determine the ſtability of ſuch veſſels, and the poſitions which they aſſume when they float freely and at reſt on the water. To accompliſh this, it is neceſſary to ſtate the principles on which that ſtability and theſe poſitions depend; and this has been done with ſo much ingenuity and ſcience by George Atwood, Eſq; F. R. S. in the Philoſophical Tranſactions for the year 1796, that we are perſuaded a large claſs of our readers will thank us for inſerting an abſtract of his memoir in this place.

A floating body is preſſed downwards by its own weight in a vertical line that paſſes through its centre of gravity; and it is ſuſtained by the upward preſſure of a fluid, acting in a vertical line that paſſes through the centre of gravity of the immerſed part; and unleſs theſe two lines be coincident, ſo that the two centres of gravity may be in the ſame vertical line, the ſolid will revolve on an axis, till it gains a poſition in which the equilibrium of floating will be permanent. Hence it appears that it is neceſſary, in the firſt place, to aſcertain the proportion of the part immerſed to the whole; for which purpoſe the ſpecific gravity of the floating body muſt be known; and then it muſt be determined, by geometrical or analytical methods, in what poſitions the ſolid can be placed on the ſurface of the fluid, ſo that the two centres of gravity already mentioned may be in the ſame vertical line when a given part of the ſolid is immerſed under the ſurface of the fluid. When theſe preliminaries are ſettled, ſomething ſtill remains to be done. Poſitions may be aſſumed in which the circumſtances juſt recited concur, and yet the ſolid will aſſume ſome other poſition in which it will permanently float. If a cylinder, *e. g.* having its ſpecific gravity to that of the fluid on which it floats as 3 to 4, and its axis to the diameter of the baſe as 2 to 1, be placed on the fluid with its axis vertical, it will ſink to a depth equal to a diameter and a half of the baſe; and while its axis is preſerved in a vertical poſition by external force, the centres of gravity of the whole ſolid and of the immerſed part will remain in the ſame vertical line: but when the external force that ſuſtained it is removed, it will decline from its upright poſition, and will permanently float with its axis horizontal. If the axis be ſuppoſed to be half of the diameter of the baſe, and be placed vertically, the ſolid will ſink to the depth of three-eighths of its diameter; and in that poſition it will float permanently. If the axis be made to incline to the vertical line, the ſolid will change its poſition until it ſettles permanently with the axis perpendicular to the horizon.

Whether, therefore, a ſolid floats permanently, or overſets when placed on the ſurface of a fluid, ſo that the centre of gravity of the ſolid and that of the part immerſed ſhall be in the ſame vertical line, it is ſaid to be in a poſition of equilibrium; and of this equilibrium there are three ſpecies, viz. the equilibrium of ſtability, in which the ſolid floats permanently in a given poſition: the equilibrium of inſtability, in which the ſolid, though the two centres of gravity already mentioned are in the ſame vertical line, ſpontaneouſly overſets, unleſs ſupported by external force; and the equilibrium of indifference, or the inſenſible equilibrium, in which the ſolid reſts on the fluid indifferent to motion, without tendency to right itſelf when inclined, or to incline itſelf farther.

If a ſolid body floats permanently on the ſurface of a fluid, and external force be applied to incline it from its poſition, the reſiſtance oppoſed to this inclination is termed the ſtability of floating. Among various floating bodies, ſome loſe their quieſcent poſition, and ſome gain it, after it has been interrupted, with greater facility and force than others.

Some ſhips at ſea (*e. g.*) yield to a given impulſe of the wind, and ſuffer a greater inclination from the perpendicular than others. As this reſiſtance to heeling or pitching, duly regulated, has been deemed of importance in the conſtruction of veſſels, ſeveral eminent mathematicians have inveſtigated rules for determining the ſtability of ſhips from their known dimenſions and weight, without recurring to actual trial. To this claſs we may refer Bouguer, Euler, Fred. Chapman, and others, who have laid down theorems for this purpoſe, founded on a ſuppoſition that the inclinations of ſhips from their quieſcent poſitions are evaneſcent, or, in a practical ſenſe, very ſmall.

"But ſhips at ſea (ſays our ingenious author) are known to heel through angles of 10° 20°, or even 30°, and therefore a doubt may ariſe how far the rules, demonſtrated on the expreſs condition that the angles of inclination are of evaneſcent magnitude, ſhould be admitted as practically applicable in caſes where the inclinations are ſo great."—"If we admit that the theory of ſtatics can be applied with any effect to the practice of naval architecture, it ſeems to be neceſſary that the rules, inveſtigated for determining the ſtability of veſſels, ſhould be extended to thoſe caſes in which the angles of inclination are of any magnitude likely to occur in the practice of navigation."

A ſolid body placed in the ſurface of a lighter fluid, at the depth correſponding to the relative gravities, cannot change its poſition by the combined actions of its weight, and the preſſure of the fluid, except by revolving on ſome horizontal axis which paſſes through the centre of gravity: but as many axes may be drawn through this point of the floating body in a direction parallel to the horizon, and the motion of the ſolid reſpects one axis only, this axis muſt be determined by the figure of the body, and the particular nature of the caſe. When this axis of motion, as it is called, is determined, and the ſpecific gravity of the ſolid is known, "the poſitions of permanent floating will be obtained, firſt by finding the ſeveral poſitions of equilibrium through which the ſolid may be conceived to paſs, while it revolves round the axis of motion; and ſecondly, by determining in which of thoſe poſitions the equilibrium is permanent, and in which of them it is momentary and unſtable."

Such as we have now briefly ſtated are the general principles, on which are founded Mr Atwood's inveſtigations for determining the poſitions aſſumed by homogeneous bodies, floating on a fluid ſurface; and alſo for determining the ſtability of ſhips and of other floating bodies. We cannot farther accompany him in his elucidation of them, in the problems to the ſolution

tion of which they lead, and in the important practical purposes of naval architecture to which they are referred. The whole paper, comprehending no less than 85 pages, is curious and valuable; it abounds with analytical and geometrical disquisitions of the most elaborate kind; and it serves to enlarge our acquaintance with a subject that is not only highly interesting to the speculative mathematician, but extremely useful in its practical application.

With this latter view, the author seems to have directed his attention to the various objects of inquiry which this article comprehends. They are such as intimately relate to the theory of naval architecture, so far as it depends on the pure laws of mechanics, and they contribute to extend and improve this theory. The union of those principles that are deduced from the laws of motion, with the knowledge which is derived from observation and experience, cannot fail to establish the art of constructing vessels on its true basis, and gradually to lead to farther improvements of the greatest importance and utility. To this purpose, the author observes, that

"If the proportions and dimensions adopted in the construction of individual vessels are obtained by exact geometrical mensurations, and calculations founded on them, and observations are made on the performance of these vessels at sea; experiments of this kind, sufficiently diversified and extended, seem to be the proper grounds on which theory may be effectually applied in developing and reducing to system those intricate, subtil, and hitherto unperceived causes, which contribute to impart the greatest degree of excellence to vessels of every species and description. Since naval architecture is reckoned among the practical branches of science, every voyage may be considered as an experiment, or rather as a series of experiments, from which useful truths are to be inferred towards perfecting the art of constructing vessels: but inferences of this kind, consistently with the preceding remark, cannot well be obtained, except by acquiring a perfect knowledge of all the proportions and dimensions of each part of the ship; and secondly, by making and recording sufficiently numerous observations on the qualities of the vessel, in all the varieties of situation to which a ship is usually liable in the practice of navigation."

In the valuable miscellany entitled the *Philosophical Magazine*, there is a paper on this subject by Mr John George English, teacher of mathematics and mechanical philosophy; which, as it is not long, and is easily understood, we shall take the liberty to transcribe.

"However operose and difficult the calculations necessary to determine the stability of nautical vessels may, in some cases, be, yet they all depend, says this author, upon the four following simple and obvious theorems, accompanied with other well known stereometrical and statical principles.

"*Theorem* 1. Every floating body displaces a quantity of the fluid in which it floats, equal to its own weight: and consequently, the specific gravity of the fluid will be to that of the floating body, as the magnitude of the whole is to that of the part immersed.

"*Theorem* 2. Every floating body is impelled downward by its own essential power, acting in the direction of a vertical line passing through the centre of gravity of the whole; and is impelled upward by the reaction of the fluid which supports it, acting in the direction of a vertical line passing through the centre of gravity of the part immersed: therefore, unless these two lines are coincident, the floating body thus impelled must revolve round an axis, either in motion or at rest, until the equilibrium is restored.

"*Theorem* 3. If by any power whatever a vessel be deflected from an upright position, the perpendicular distance between two vertical lines passing through the centres of gravity of the whole, and of the part immersed respectively, will be as the stability of the vessel, and which will be positive, nothing, or negative, according as the metacentre is above, coincident with, or below, the centre of gravity of the vessel.

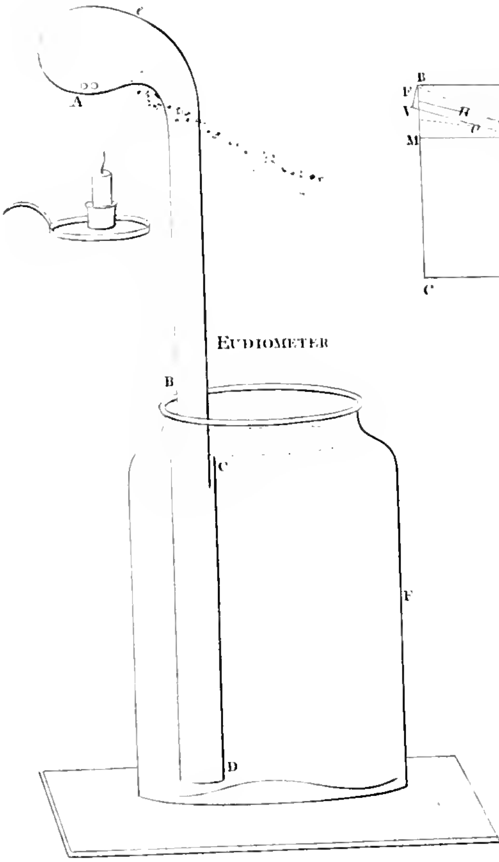
"*Theorem* 4. The common centre of gravity of any system of bodies being given in position, if any one of these bodies be moved from one part of the system to another, the corresponding motion of the common centre of gravity, estimated in any given direction, will be to that of the aforesaid body estimated in the same direction, as the weight of the body moved is to that of the whole system.

"From whence it is evident, that in order to ascertain the stability of any vessel, the position of the centres of gravity of the whole, and of the part immersed, must be determined; with which, and the dimensions of the vessel, the line of floatation, and angle of deflection, the stability or power either to right itself or overturn, may be found.

"In ships of war and merchandize, the calculations necessary for this purpose become unavoidably very operose and troublesome; but they may be much facilitated by the experimental method pointed out in the New Transactions of the Swedish Academy of Sciences, first quarter of the year 1787, page 48.

"In river and canal boats, the regularity and simplicity of the form of the vessel itself, together with the compact disposition and homogeneal quality of the burden, render that method for them unnecessary, and make the requisite calculations become very easy. Vessels of this kind are generally of the same transverse section throughout their whole length, except a small part in prow and stern, formed by segments of circles or other simple curves; therefore a length may easily be assigned such, that any of the transverse sections being multiplied thereby, the product will be equal to the whole solidity of the vessel. The form of the section ABCD is for the most part either rectangular, as in fig. 1. trapezoidal, as in fig. 2. or mixtilineal as in fig. 3. in all which MM represents the line of floatation when upright, and EF that when inclined at any angle MXE; also G represents the centre of gravity of the whole vessel, and R that of the part immersed. Plate XXVIII.

"If the vessel be loaded quite up to the line AB, and the specific gravity of the boat and burden be the same, then the point G is simply the centre of gravity of the section ABCD; but if not, the centres of gravity of the boat and burden must be found separately, and reduced to one by the common method, namely, by dividing the sum of the momenta by the sum of weights, or areas, which in this case are as the weights. The point R is always the centre of gravity of the section MMCD, which, if consisting of different figures, must also be found by dividing the sum of the momenta by the sum of the weights as common. These two points being found, the



FLOATING BODIES

EUPHORBIA

Fig 1.

Fig 2.

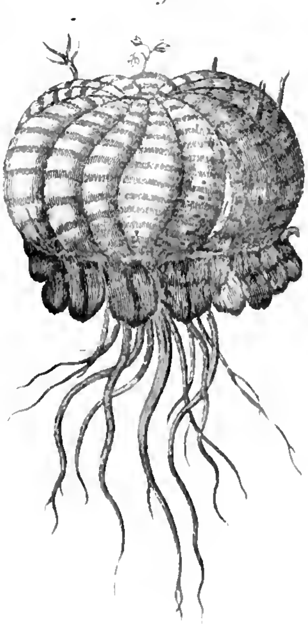

Fig 3.

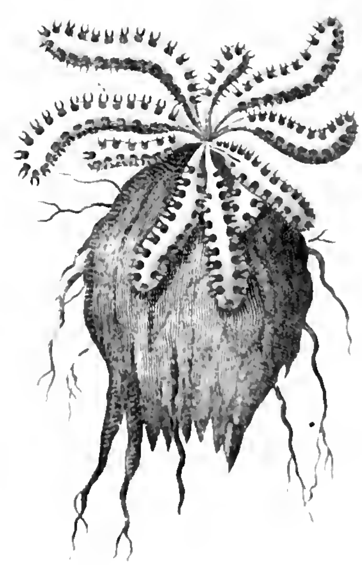

Floating.

the next thing neceſſary is to determine the area of the two equal triangles MXE, MXF, their centres of gravity *o*, *o*, and the perpendicular projected diſtance *n n* of theſe points on the water line EF. This being done, through R, and parallel to EF draw RT=a fourth proportional to the whole area MMCD, either triangle MXE or MXF, and the diſtance *n n*; through T, and at right angles to RT or EF, draw TS meeting the vertical axis of the veſſel in S the metacentre; alſo through the points G, B, and parallel to ST, draw NGW and BV; moreover through S, and parallel to EF, draw WSV, meeting the two former in V and W; then SW is as the ſtability of the veſſel, which will be poſitive, nothing or negative, according as the point S is above, coincident with, or below, the point G. If now we ſuppoſe W to repreſent the weight of the whole veſſel and burden (which will be equal to the ſection MMCD multiplied by the length of the veſſel), and P to repreſent the required weight applied at the gunwale B to ſuſtain the veſſel at the given angle of inclination; we ſhall always have this proportion: as VS : SW : : W : P; which proportion is general, whether SW be poſitive or negative; it muſt only in the latter caſe be ſuppoſed to act upward to prevent an overturn.

"In the rectangular veſſel, of given weight and dimenſions, the whole proceſs is ſo evident, that any farther explanation would be unneceſſary. In the trapezoidal veſſel, after having found the points G and R, let AD, BC be produced until they meet in K. Then, ſince the two ſections MMCD, EFDC are equal, the two triangles MMK, EFK are alſo equal; and therefore the rectangle EK × KF = KM × KM = $\overline{KM}^2$; and ſince the angle of inclination is ſuppoſed to be known, the angles at E and F are given. Conſequently, if a mean proportional be found between the ſines of the angles at E and F, we ſhall have the following proportions:

"As the mean proportional thus found : ſine ∠ E : : KM : KF, and as the ſaid mean proportional : ſine ∠ F : : KM : KE; therefore ME, MF become known: from whence the area of either triangle MXE or MXF, the diſtance *n n*, and all the other requiſites, may be found.

"In the mixtilineal ſection, let AB = 9 feet = 108 inches, the whole depth = 6 feet = 72 inches, and the altitude of MM the line of floatation 4 feet or 48 inches; alſo let the two curvelinear parts be circular quadrants of two feet, or 24 inches radius each. Then the area of the two quadrants = 904·7808 ſquare inches, and the diſtance of their centres of gravity from the bottom = 13·8177 inches very nearly; alſo the area of the included rectangle *a b i e* = 1440 ſquare inches, and the altitude of its centre of gravity 12 inches; in like manner, the area of the rectangle AB *c d* will be found = 5184 ſquare inches, and the altitude of its centre of gravity 48 inches: therefore we ſhall have

Momentum of the two quad.	= 904·7808	× 13·8177	=	12501·98966016
Moment. of the rectan. *a b i e*	= 1440·	× 12	=	17280·
Moment. of the rectan. AB *c d*	= 5184·	× 48	=	248832·
	7528·7808			278613·98966016

Floating ‖ Florida.

"Now the ſum of the momenta, divided by the ſum of the areas, will give $\frac{278613·98966016}{7528·7808}$ = 37·006 inches, the altitude of G, the centre of gravity of the ſection ABCD above the bottom. In like manner, the altitude of R, the centre of gravity of the ſection MMCD, will be found to be equal $\frac{123093·98966016}{4936·7808}$ = 24·934 inches; and conſequently their difference, or the value of GR = 12·072 inches will be found.

Suppoſe the veſſel to heel 15°, and we ſhall have the following proportion; namely, As radius : tangent of 15° : : MX = 54 inches : 14·469 inches = ME or MF; and conſequently the area of either triangle MXE or MXF = 390·663 ſquare inches. Therefore, by theorem 4th, as 4936·7808 : 390·663 : : 72 = *n n* = ⅔ AB : 5·6975 inches = RT; and, again, as radius : ſine of 15° : : 12·072 = GR : 3·1245 inches = RN; conſequently RT—RN = 5·6975—3·1245 = 2·573 inches = SW, the ſtability required.

"Moreover, as the ſine of 15° : radius : : 5·6975 = RT : 22·013 = RS, to which, if we add 24·934, the altitude of the point R, we ſhall have 46 947 for the height of the metacentre, which taken from 72, the whole altitude, there remains 25·053; from which, and the half width = 54 inches, the diſtance BS is found = 59·529 inches very nearly, and the angle SBV = 80°—06′—42″; from whence SV = 58·645 inches.

Again: Let us ſuppoſe the mean length of the veſſel to be 40 feet, or 480 inches, and we ſhall have the weight of the whole veſſel equal to the area of the ſection MMCD = 4936·7808 multiplied by 480 = 2369654·784 cubic inches of water, which weighs exactly 85708 pounds avoirdupoiſe, allowing the cubic foot to weigh 62·5 pounds.

"And, finally, as SV : SW (*i. e.*) as 58·645 : 2·573 : : 85708 : 3760 +, the weight on the gunwale which will ſuſtain the veſſel at the given inclination. Therefore a veſſel of the above dimenſions, and weighing 38 tons, 5 cwts. 28 lbs. will require a weight of 1 ton, 13 cwts. 64 lbs. to make her incline 15°.

"In this example, the deflecting power has been ſuppoſed to act perpendicularly on the gunwale at B; but if the veſſel is navigated by ſails, the centre velique muſt be found; with which, and the angle of deflection, the projected diſtance thereof on the line SV may be obtained; and then the power, calculated as above, neceſſary to be applied at the projected point, will be that part of the wind's force which cauſes the veſſel to heel. And converſely, if the weight and dimenſions of the veſſel, the area and altitude of the ſails, the direction and velocity of the wind be given, the angle of deflection may be found."

FLORIDA, a townſhip in Orange co. New-York, 6 or 8 miles S. of Goſhen, and 50 N. W. of New-York city. 377 of its inhabitants are qualified to be electors. It has been lately incorporated.—*Morſe.*

Florida, *Eaſt* and *Weſt*, belonging to Spain, ſituated between 25. and 31. N. lat. and between 80. and 91. W. long. about 600 miles in length. Its breadth is various; the broadeſt part of Weſt Florida is about 130 miles, while the narrow peninſula of Eaſt Florida extends, in the ſame direction, from S. to N. 400 miles. It is bounded N. by Georgia, S. by the gulf of Mexico, E. by the Atlantic ocean, and W. by the Miſſiſip-

pi,

pi, which separates it from Louisiana, and is nearly of the form of the letter L. Among its rivers that fall into the Atlantic, St. John's and Indian rivers are the chief. Seguana, Appalachicola, Chatahatchi, Escambia, Mobile, Pascagoula and Pearl rivers all rise in Georgia, and run southerly into the gulf of Mexico. The principal bays are St Bernard's, Ascension, Mobile, Pensacola, Dauphin, Joseph, Apalachy, Spiritu Sancto; and the chief capes are Blanco, St Blaize, Anclote, and cape Florida at the extremity of the peninsula. The climate is little different from that of Georgia. There are, in this country, a great variety of soils; the eastern part of it, near to, and about St Augustine, is by far the most unfruitful; yet even there, two crops of Indian corn are annually produced. The banks of the rivers which water the Floridas, and the parts contiguous, are of a superior quality, and well adapted to the culture of rice and corn. The fine lands near the river Escambia, are described under the account of that river. The interior country, which is high and pleasant, abounds with wood of almost every kind; particularly white and red oak, live oak, laurel magnolia, pine, hickory, cypress, red and white cedar. The live oaks, though not tall, contain a prodigious quantity of timber. The trunk is generally from 12 to 20 feet in circumference, and rises 10 or 12 feet from the earth, and then branches into 4 or 5 great limbs, which grow in nearly a horizontal direction, forming a gentle curve. "I have stepped" says Bartram, "above 50 paces, on a straight line, from the trunk of one of these trees to the extremity of the limbs." They are ever green, and the wood almost incorruptible. They bear a great quantity of small acorns, which is agreeable food when roasted, and from which the Indians extract a sweet oil, which they use in cooking homminy and rice.

The laurel magnolia is the most beautiful among the trees of the forest, and is usually 100 feet high, though some are much higher. The trunk is perfectly erect, rising in the form of a beautiful column, and supporting a head like an obtuse cone. The flowers, which are on the extremity of the branches, are large, white, and expanded like a rose, and are the largest and most complete of any yet known; when fully expanded, they are from 6 to 9 inches diameter, and have a most delicious fragrance. The cypress is the largest of the American trees. "I have seen trunks of these trees," says Bartram, "that would measure 8, 10 and 12 feet in diameter, for 40 and 50 feet shaft." The trunks make excellent shingles, boards, and other timber; and when hollowed, make durable and convenient canoes. The garden vegetables are in high perfection; the orange and lemon trees grow here, without cultivation, to a large size, and produce better fruit than in Spain and Portugal. The intervales between the hilly parts of this country are extremely rich. The principal town in West Florida is Pensacola; in East Florida St Augustine.

The Spanish strength in the Floridas, and Louisiana, in 1790, was as follows, according to Mr Melford's account: Troops and levies at St Augustine and on St John's river, 400—St Marks, 100—Pensacola, 350—Mobile and Tombigbee, 150—at the Natchez, 200—Red river, 100—Illinois river, 300—in all 1600 men, called the Orleans or Louisiana regiment.

The number of American families that have been Spanish subjects since 1783, amounts to 1720, viz. at Tensau, near Mobile bay, 90—on Tombigbee river, 130—at the Natchez on the Mississippi, 1500. All the settlers in these districts are under the immediate orders of the military commandants, and subject to martial law; with an appeal from stage to stage, up to the viceroy of Mexico. The property of the subject at his decease is to be managed by the commandant, whose fees, by law, are enormous.

Until the year 1586 the continent of North-America went by the name of Florida. It received this name from John Ponce, because when he landed in N. lat. 38. 8. in April 1513, he found the country there in full bloom. Florida has frequently changed masters, belonging alternately to the French and Spaniards. West-Florida, as far as Perdido river, was owned and occupied by the French; the remainder, and all East-Florida, by the Spaniards, previous to their being ceded to the British, at the peace of 1763. The British divided this country into E. and W. Florida. During the American war, both the Floridas were reduced by the Spaniards, and guarantied to the crown of Spain by the definitive treaty of 1783.—*ib.*

Florida, Cape, the southernmost point of land of the peninsula of East-Florida. It is 100 miles N. of the island of Cuba. N. lat. 25. 20. W. long. 80. 20.—*ib.*

Florida Keys, or *Martyr's Islands*, a number of rocks and sand banks, bounded W. by the gulf of Mexico, E. by that of Florida. The great sand bank extends from the peninsula of East-Florida inward, to the gulf of Mexico, in the form of a hook; its W. point is divided from the bank called the Dry Tortugas, by Tortuga channel.—*ib.*

Florida, Gulf of, is the channel between the peninsula of Florida and the Bahama islands, N. of the island of Cuba; and through which the Gulf Stream finds a passage, and runs to the N. E. along the American coast.—*ib.*

FLOWERTOWN, in Pennsylvania, is a small village about 12 miles N. of Philadelphia, in Montgomery co.—*ib.*

FLUENT, or Flowing Quantity, in the doctrine of fluxions, is the variable quantity which is considered as increasing and decreasing; or the fluent of a given fluxion, is that quantity whose fluxion being taken, according to the rules of that doctrine, shall be the same with the given fluxion. See Fluxions. *Encycl.*

FLUIDS, Motion in. See Hydrostatics and Resistance of Fluids, *Encycl.* and Motion in this *Supplement*.

FLUSHING, a town in Queen's co. New-York, situated on the N. W. part of Long Island, and on the S. side of Hell Gate; 7 miles E. by N. of New-York city. It contains 1607 inhabitants; of whom 210 are qualified electors, and 340 are slaves.—*Morse.*

FLUVANNA, a county of Virginia, bounded N. by Albemarle, N. E. by Louisa, E. by Goochland, W. by Amherst, and S. by Fluvanna or James river, which divides it from Buckingham. It is about 22 miles long, and 20 broad, and contains 3,921 inhabitants, including 1,466 slaves. There is great plenty of of marble, both white and variegated with blue, red and purple veins, found here, on James river, at the mouth of Rockfish; where it forms a large precipice, overhanging a navigable part of the river.—*ib.*

FOGEDAR, the military governor of a subordinate district in India, who has sometimes the additional office of collecting the revenues.

FOGGY *Cape*, on the N. W. coast of N. America, is situated on the S. eastern side of the peninsula of Alaska, and W. of Kilhtac island.—*Morse.*

FOGGY *Isle*, on the same side of the peninsula as the above, lies a short way S. by W. of Foggy Cape. —*ib.*

FOLIATE, a name given by some to a curve of the 2d order, expressed by the equation $x^3+y^3=axy$, being one species of defective hyperbolas, with one asymptote, and consisting of two infinite legs crossing each other, forming a sort of leaf. It is the 42d species of Newton's Lines of the 3d Order.

FOLLOWFIELD, a township in Washington co. Pennsylvania. East and West Followfield are also two townships, in Chester co. Pennsylvania.—*Morse.*

FONSECA, Gulf of, lies in New-Spain on the Pacific ocean, 40 miles S. E. of the town of St Miguel, and about 290 miles N. W. of Cape Blanco, on the western side of the gulf of Nicoya —*ib.*

FONTAIN, Belle, a settlement in the N. W. territory, situated on the E. side of the Mississippi, about 18 miles N. of St Phillips, and 23 below Cahokia.—*ib.*

FONT, or Fonte, Straits de, lie on the N. W. coast of N. America, in N. lat. 54. 35. W. long. 9. 55. There is a large island in the middle of the entrance. This is thought to be the same strait that De Fonte, a Spanish admiral, discovered in 1640, whose account of it has been long treated as fabulous. It has been seen by captains Gray and Ingraham, of Boston.—*ib.*

FORALONES, in the island of Gunra, and coast of Peru, in S. America, are old walls of some ancient building in the time of the Yncas, which serve here as light-houses for the shipping which sail from Callao to Paita, on the S. Sea coast.—*ib.*

FORCER, in mechanics, is properly a piston without a valve. For, by drawing up such a piston, the air is drawn up, and the water follows; then pushing the piston down again, the water, being prevented from descending by the lower valve, is forced up to any height above, by means of a side branch between the two.

FORDYCE (James, D. D.) so well known to serious readers by his sermons to young women and other specimens of pulpit eloquence, was born at Aberdeen in the year 1720. His father was a man much esteemed, and held, more than once, the office of chief magistrate in his native city; and his mother was a woman of good sense, amiable temper, and exemplary piety. This respectable pair had the singular felicity of transmitting superior talents to almost every individual of a numerous family; of one of which, viz. David Fordyce, the reader will find some account in the *Encyclopædia*.

The subject of this memoir, who was their fourth son, acquired, as well as his brother, the rudiments of classical learning at the grammar school of Aberdeen, whence he was removed to the Marischal college and university in the same city. Having completed a regular course of study both in philosophy and theology, he was licensed, when very young, according to the forms of the church of Scotland, to be a preacher of the gospel; and was soon afterwards preferred to the place of second minister in the collegiate church of Brechin in the county of Angus. After remaining there for some years, he received a presentation to the church of Alloa near Stirling; and though the inhabitants of that parish were prepossessed in favour of another minister whom they knew, and prejudiced against Mr Fordyce whom they did not know; so narrow minded and totally destitute of taste was his colleague in Brechin, that he judged it expedient to hazard the consequences of a removal. He was aware that he entered on his new charge under a considerable degree of popular odium; but he thought it more probable that he should be able to overcome that odium, than conciliate the affections of a sour fanatic. In this expectation he was not deceived. The prejudices of the good people in Alloa were very quickly removed, not more by the able and impressive manner in which he conducted the public services of the Lord's day, than by the amiable and condescending spirit with which he performed the more private duties of visiting and catechising in the different districts of his parish; duties which, as they were wont to be performed by the Scotch clergy, contributed much more than preaching to the religious instruction of the lower classes of the people.

It was during his residence at Alloa that Mr Fordyce first distinguished himself as an author by the successive publication of the three following sermons. The first, upon the eloquence of the pulpit, was annexed to "the Art of Preaching" by his brother David; the second, upon the methods of promoting edification by public institutions, was preached at the ordination of the Rev. Mr Gibson minister of St Ninian's, a neighbouring parish, in the year 1754, and published, with the charge and notes in 1755; and the third, upon the delusive and persecuting spirit of popery, was preached the same year before the synod of Stirling and Perth: and being published, came very quickly to a second edition. But the sermon which most strongly arrested the attention, both of the audience before which it was delivered, and of the public to which, in 1760, it was given from the press, was that on the *folly, infamy, and misery of unlawful pleasure*, preached before the General Assembly of the Church of Scotland. The choice of such a subject on such an occasion, excited the surprise of all his hearers, and tempted the younger part of them to smile at the very reading of the text; but this unseasonable mirth was soon converted into seriousness. The picture exhibited in this sermon is the work of a master; and we have been assured by a friend who heard it preached, that the spirit and elegance of the composition was so seconded by the solemnity and animation with which it was delivered, that it made a very striking impression, not only upon the more respectable part of the audience, but upon minds of noted levity: It raised indeed its writer's fame as a pulpit-orator to an unrivalled eminence among his brethren in Scotland.

About this time, and we believe in consequence of this sermon, Mr Fordyce received from the university of Glasgow a diploma, creating him Doctor in Divinity;

nity; and if there is yet any thing honourable in academical degrees, prostituted as they have long been by an undistinguishing distribution, the honour could not have been conferred with greater propriety on any man in the church to which he then belonged.

In that church he did not long remain. Soon after the publication of this singular sermon, and his consequent acquisition of academical honours, he accepted of an invitation from a society of Protestant dissenters, who had their place of meeting in Monkwell-street, London, to become colleague and successor to their pastor, who was then old and infirm, and who died indeed in the space of a few months. This gave occasion to the Doctor to display his oratory once more both from the pulpit and the press in a sermon on the death of Dr Lawrence. He was now sole pastor to the congregation of Monkwell-street; and preached for many years, with great powers of eloquence and fervor of piety, to an audience always crowded and often overflowing.

When a preacher obtains, with or without merit, an uncommon share of popularity, a considerable proportion of his hearers will ever consist of those, who are guided in their choice rather by curiosity and fashion, than by sound judgment. The attachments of such people are as capricious and variable as their minds; and they change their preacher as they change their dress, not from their own taste, for in general they have none; but from the desire of being where others are, of doing what others do, and of admiring what others admire. Dr Fordyce appreciated justly the value of such men's approbation, and knew it eventually by experience; but he was more than compensated for the loss of hearers of this description by the steady adherence of others, whose esteem was most desirable, because it was grounded upon the dictates of a sound understanding.

At last, about Christmas 1782, when his health, which had long been declining, rendered it necessary, in his own opinion, and in the opinion of his physicians, to discontinue his public services, he resigned his charge in Monkwell-street, and retired to a villa in Hampshire, in the neighbourhood of the Earl of Bute, who honoured him with his friendship, and to whose valuable library he had free access. Afterwards he removed to Bath, where having, with Christian patience, suffered much from an asthmatic complaint, to which he had been subject for some years, on the 1st of October 1796 he expired without a groan.

Were we to hazard an opinion of Dr Fordyce's intellectual powers from such a perusal of his works as we must acknowledge to have been hasty, we would say that he was a man of genius rather than of judgment; that his imagination was the predominant faculty of his mind; and that he was better fitted, by an address to the passions, to enforce the practice of virtue, than, by the exertions of his own understanding, to vindicate speculative truth, or to detect the sophistry of error. From this remark, we cannot be suspected of a wish to lessen his character in the public esteem; for his talents, as they appear to us, are surely of more value to a preacher than those which are perhaps better adapted to literary or scientific pursuits. In none of his work indeed do we perceive any evidence either of profound science, or of various erudition; though we doubt not but those works are every thing which their author intended them to be. Of his sermons to young women, which have attracted most general notice, it would be presumptuous in us to give a character; for though we sat down many years ago to read them, we could not get through; and we have never made a second attempt. As far as we can depend upon what we recollect of these far-famed discourses, the censure passed on them by Mrs Wolstoncraft seems to be just. Their author, however, was certainly qualified to excel, and actually did excel as a preacher. We have already mentioned with approbation three or four of his occasional sermons; but perhaps the finest specimen of pulpit oratory which ever fell from his pen, is the charge which he delivered at the ordination of his successor in the meeting of Monkwell-street. It is indeed one of the most valuable discourses of the kind that we have seen, and should be read with attention by every clergyman of every denomination, who wishes to discharge his duty with credit to himself and with advantage to his people.

The effect of Dr Fordyce's addresses from the pulpit was much heightened, not only by an action and an elocution, which he studied with care and practised with success; but by the figure of his person, which was peculiarly dignified, and by the expression of his countenance, which was animated at all times, but animated most of all when lighted up by the ardor of his soul in the service of God. By some of his hearers, it was observed that, on many occasions, he seemed not merely to speak, but to look conviction to the heart. His eye, indeed, was particularly bright and penetrating, and he had carefully attended to the effect which an orator may often produce upon an audience by the judicious use of that little, but invaluable organ.

With respect to his theological sentiments, we are assured (A) they were in no extreme, but liberal, rational, and manly. He seems to have been untainted by that rage of innovation, which of late has so completely disfigured the creed, as well religious as political, of the great body of English dissenters. The consequence was, that he lived on terms of friendship with men of very opposite sentiments; with Price a republican and Arian, and with Johnson, who, though he hated a whig and a Presbyterian, respected talents and worth wherever he found them.

We shall conclude this short sketch of Dr Fordyce's life and character with the following list of his works, of which some have been translated into several languages. 1. A Sermon and Charge, at the ordination of the Rev. Mr Gibson Minister of St Ninian's, 1754. 2. Another Ordination Sermon on the Eloquence of the Pulpit, annexed to his brother's "Art of Preaching," 1754. 3. A Sermon on the Spirit of Popery, 1754. 4. A Sermon on the Folly, Infamy, and Misery of Unlawful Pleasure, 1760. 5. A Sermon on the Death of Dr Lawrence, 1760. 6. Sermons to Young Women, 2 vols. 1765. 7. A Sermon on the Character

(A) By his successor in Monkwell-street, to whose sermon, preached on occasion of the Doctor's death, our readers are indebted for every thing valuable in this short memoir.

Character and Conduct of the Female Sex, 1776. 8. Addresses to young men, 2 vols. 1777. 9. A Charge at the Ordination of the Rev. James Lindsey, in Monkwell-street, 1783. 10. Addresses to the Deity, 1785. 11. Poems, 1786. 12. A Discourse on Pain, 1791. He also re-published, with an additional character, "The Temple of Virtue, a Dream," written by his brother David.

FORESTERTON, a village in Burlington co. New-Jersey, which lies between Ayerston and Evesham; about 15 miles E. of Philadelphia, and 11 S. of Burlington city.—*Morse*.

FOREST, a small island in the British territories, at the mouth of Lake Ontario, between which and Grand Island is a narrow channel. It lies 9 miles southerly of Fort Frontinac, and 6 N. westerly of Roebuck island in the same lake, and within the line of the United States.—*ib.*

FORKED DEER, a navigable river in Tennessee, which runs westerly into Mississippi river, between the Obian and Hatchy. It is about 76 yards wide, 7 miles from its mouth.—*ib.*

FORKS, a township in Northampton co. Pennsylvania.—*ib.*

FORMULA, a theorem or general rule or expression, for resolving certain particular cases of some problem, &c. So $\frac{1}{2}s + \frac{1}{2}d$ is a general formula for the greater of two quantities whose sum is s and difference d; and $\frac{1}{2}s - \frac{1}{2}d$ is the formula, or general value, for the less quantity. Also $\sqrt{dx - x^2}$ is the formula, or general value, of the ordinate to a circle, whose diameter is d, and absciss x.

FORSTER (John Reinhold, L.L.D.) professor of natural history in the university of Halle, member of the academy of sciences at Berlin, and of other learned societies, was born at Dirschau, in West Prussia, in the month of October 1729, and was formerly a Protestant clergyman at Dantzick. He had a numerous family, and the emoluments of his office were slender. He therefore quitted Dantzick, and went, first to Russia, and thence to England, in quest of a better settlement than his own country afforded. In the dissenting academy at Warrington he was appointed tutor in the modern languages, with the occasional office of lecturing in various branches of natural history. For the first department he was by no means well qualified; his extraordinary knowledge of languages, ancient and modern, being unaccompanied by a particle of taste; and his use of them being all barbarous, though fluent. As a natural historian, a critic, geographer, and antiquary, he ranked much higher; but, unfortunately, these were acquisitions of little value in his academical department.

At length he obtained the appointment of naturalist and *philosopher* (if the word may be so used) to the second voyage of discovery undertaken by Capt. Cook; and from 1772 to 1775 he accompanied that immortal navigator round the world. On his return he resided in London, till the improper conduct of himself and his son made it expedient for them both to leave the kingdom. Fortunately he received an invitation to Halle, where, for 18 years, he was a member of the philosophical and medical faculties. Among his works are: An Introduction to Mineralogy, or, An accurate Classification of Fossils and Minerals, &c. London, 1768, 8vo. A Catalogue of the Animals of North America, with short Directions for collecting, preserving, and transporting all kinds of Natural Curiosities, London, 1771, 8vo. Observations made during a Voyage round the World, on Physical Geography, &c. London, 1778. He was the author of a great many productions in English, Latin, or German, and of several papers in the Philosophical Transactions. He translated into English, Bougainville's Voyage round the World, and Kalm's, Bossu's, and Reidsel's Travels. He was employed likewise, when in England, in the Critical Review; and he wrote various detached papers on different subjects, which have been inserted in foreign journals and the transactions of learned academies.

He died at Halle on the 16th of December 1798, in the 70th year of his age.

FORSTER (George), the son of the preceding, was born at Dantzick, and accompanied his father to England when he was about twelve years of age. He was entered a student in the academy at Warrington, and soon acquired a very perfect use of the English tongue. He also distinguished himself greatly by his attainments in science and literature in general; adding to an excellent memory, quick parts and a fertile imagination. His temper was mild and amiable; in which he much differed from his father, one of the most quarrelsome and irritable of men; by which disposition, joined to a total want of prudence in common concerns, he lost almost all the friends his talents had acquired him, and involved himself and family in perpetual difficulties.

The case was very different with the subject of this memoir; for when Dr Forster was appointed naturalist to captain Cook, his son, through the interest of the friends whom his good nature had made, was associated with him in his office. The voyage continued during the space of three years; and on their return the two Forsters published jointly a botanical work in Latin, contained the characters of a number of new *genera* of plants, discovered by them in their circumnavigation. Thus far they acted properly in the service of government for the advancement of science; but in publishing another work their conduct was not proper.

The father had come under an engagement not to publish separately, from the authorised narrative, any account of the voyage; and this engagement he and his son were determined to violate. An account of the voyage, therefore, was published in English and German by *George*; and the language, which is correct and elegant, was undoubtedly his; but those who knew both him and his father, are satisfied that the matter proceeded from the joint stock of their observations and reflections. Several parts of the work, and particularly the elaborate investigations relative to the languages spoken by the natives of the South Sea Islands, and the speculations concerning their successive migrations, are thought to be strongly impressed with the genius of the elder Forster.

That a work thus surreptitiously ushered into the world was not patronised by those with whom the authors had so ungratefully broken faith, could excite no wonder, even though the publication itself had been otherwise unexceptionable; but this was far from being the case. It abounds with reflections injurious to the government whose servants they had been, and not just

to

to the navigators employed on voyages of discovery. The younger Forster, too, had some time before published a book replete with factious sentiments; and the coldness with which he and his father were both treated in consequence of such conduct, determined them to leave London.

We have already related all that we know of the father, who was recommended to our notice only by his connection with the illustrious Cook; and of the son, there is a short account in the Monthly Magazine, by Charles Pougens, fraught with those impious and seditious reflections which so frequently disgrace a miscellany, which would otherwise be highly valuable. According to this author, George Forster was desirous to settle in France. Avaricious of glory, and an idolator of liberty, Paris was the city most suitable to his taste and character of any in Europe. Notwithstanding this, he was soon constrained to leave it: the interest of his family demanded this sacrifice; for a learned man, who sails round the world, may enrich his memory, but he will not better his fortune. He was accordingly obliged to accept the place of professor of natural history in the university of Cassel. But his factious spirit accompanied him whithersoever he went. It is well known, that the petty princes of Germany have long been in the practice of hiring out their troops to more opulent sovereigns engaged in war. This practice, which we are not disposed to defend, not only scandalized our Cosmopolite, but so irritated his temper and offended his pride, because forsooth, the Prince of Hesse-Cassel would not by *him* be persuaded to relinquish it, that he did every thing in his power, we are told, to withdraw himself from a situation so unsuitable to a thinking being. Every thing in his power! Did the Prince retain him in the university contrary to his inclination? The university of Cassel must be contemptible indeed, if the prelections of such a man as George Forster were of such consequence to it.

He got away, however, and the senate of Poland having offered him a chair in the university of Wilna, Forster accepted of the invitation. But although this office was very lucrative, and the enlightened patriots of that country did not neglect to procure him all the literary succours of which he stood in need, he could not be long happy in a semi-barbarous nation, in which liberty was suffered to expire under the intrigues of Russia and Prussia.

On this, with wonderful consistency, the man who could not endure the despotism of Hesse, or even the aristocracy of England, accepted of the propositions of that friend to liberty Catharine II; who, jealous of every species of glory, wished to signalize her reign, by procuring to the Russian nation the honour of undertaking, after the example of England and France, a new voyage of discovery round the world. Unfortunately for the progress of knowledge, the war with the Ottoman Porte occasioned the miscarriage of this useful project.

But Forster could not long remain in obscurity. The different publications with which he occasionally enriched natural history and literature, encreased his reputation. The Elector of Mentz accordingly appointed him president of the university of the same name; and he was discharging the functions of his new office when the French troops took possession of the capital. This philosophical traveller, who had studied society under all the various aspects arising from different degrees of civilization; who had viewed man simple and happy at Otaheite;—an eater of human flesh in New-Zealand, corrupted by commerce in England, depraved in France by luxury and atheism, in Brabant by superstition, and in Poland by anarchy;—beheld with wild enthusiasm the dawnings of the French revolution, and was the first, says M. Pougens, to promulgate republicanism in Germany.

The *Mayencois*, who had formed themselves into a national convention, sent him to Paris, in order to solicit their *reunion* with the French republic. But, in the course of his mission, the city of Mentz was besieged and retaken by the Prussian troops. This event occasioned the loss of all his property; and what was still more disastrous, that of his numerous manuscripts, which fell into the hands of the Prince of Prussia.

Our biographer, after conducting his hero through these scenes of public life, proceeds to give us a view of his domestic habits and private principles. He tells us, that he formed a connection (whether a marriage or not, the studied ambiguity of his language leaves rather uncertain) with a young woman named *Theresa Hayne*, who, by the illumination of French philosophy, had divested herself of all the prejudices which, we trust, the ladies of this country still consider as their honour, as they are certainly the guardians of domestic peace. Miss Hayne was indignant at the very *name of duty*. With Eloisa she had taken it into her head, that

> Love, free as air, at sight of human ties,
> Spreads his light wings, and in a moment dies.

She was frank enough, however, says our author, to acknowledge the errors of her imagination; and from this expression, and his calling her afterwards Forster's wife, we are led to suppose that she was actually married to him. But their union, of whatever kind, was of short duration. Though the lady is said to have been passionately attached to celebrated names, the *name* of George Forster was not sufficient to satisfy her. He soon ceased, we are informed, to *please* her; she therefore transferred her affections to another; and, as was very natural for a woman who was indignant at the name of duty, she proved false to her husband's bed. Forster, however, pretended to be such a friend to the *modern* rights of men and women, that he defended the character of his Theresa against crowds who condemned her conduct. Nay, we are told, that he considered himself, and every other husband, who ceases to please, as the *adulterer of nature*. He therefore laboured strenuously to obtain a divorce, to enable Theresa Hayne to espouse the man whom she preferred to himself. Strange, however, to tell, the prejudices even of this Cosmopolite were too strong for his principles. While he was endeavouring to procure the divorce, he made preparations at the same time, by the study of the oriental languages, to undertake a journey to Thibet and Indostan, in order to remove from that part of the world, in which both his heart and his person had experienced so severe a shock. But the chagrin occasioned by his misfortunes, joined to a scorbutic affection,

tion, to which he had been long ſubject, and which he had contracted at ſea during the voyage of circumnavigation, abridged his life, and prevented him from realiſing this double project. He died at Paris, at the age of thirty-nine, on the 13th of February 1792.

This is a ſtrange tale; but we truſt it will not prove uſeleſs. The latter part of it at leaſt ſhows, that when men diveſt themſelves of the principles of religion, they ſoon degenerate from the dignity of philoſophers to the level of mere ſenſualiſts; and that the woman, who can, in defiance of decorum and honour, transfer her affections and her perſon from man to man, ranks no higher in the ſcale of being than a female brute of more than common ſagacity. It ſhews likewiſe, that the contempt of our modern ſages for thoſe partial attachments which unite individuals in one family, is a mere pretence; that the dictates of nature will be heard; and the laws of nature's God obeyed. George Forſter, though he was ſuch a zealous advocate for liberty and equality, as to vindicate the adultery of his wife; yet felt ſo ſenſibly the wound which her infidelity inflicted on his honour, that he could not ſurvive it, but periſhed, in conſequence, in the flower of his age.

Royal FORT, is one whoſe line of defence is at leaſt 26 fathoms long.

Star Fort, is a ſconce or redoubt, conſtituted by reentering and ſaliant angles, having commonly from five to eight points, and the ſides flanking each other.

FORT BALIZE, at the mouth of Miſſiſſippi river, lies 105 miles below the city of New-Orleans.—*Morse.*

Fort Blount, ſtands on Cumberland river, in the ſtate of Tenneſſee.—*ib.*

Fort Brewington, in New-York ſtate, is ſituated at the W. end of Oneida Lake, and on the N. ſide of Onondago river, at its mouth in the lake.—*ib.*

Fort Chartres, in the N. W. territory, is ſituated on the E. bank of Miſſiſſippi river, 6 miles W. by S. of St Phillips, and 19 W. N. W. of Kaſkaſkias village. —*ib.*

Fort Dauphin, a ſmall lake, or rather arm of Little Winnipeg lake, and weſt of it.—*ib.*

Fort Edward, a pleaſant village in Waſhington co. New-York, on the E. bank of Hudſon river, 49 miles N. of Albany. It has its name from the large fort built here in 1755; of which there are no remains but large mounds of earth.—*ib.*

Fort Anne, a village on the head-waters of Wood creek, in Waſhington co. New-York, 60 miles N. E. of Albany city. It has its name from a ſmall picket fort, erected in the reign of Queen Anne, of which there is no veſtige left.—*ib.*

Fort George, lies at the S. end of lake George, 62 miles N. of Albany. Here are the remains of the old forts, George, and William Henry. The ſituation is pleaſant, but there is hardly the appearance of a village.—*ib.*

Fortroyal, in the iſland of Grenada.—*ib.*

Fortroyal, one of the principal towns in the iſland of Martinico, in the Weſt-Indies. It is the ſeat of government in the iſland; its ſtreets are regular, the houſes agreeable, and the people gay and luxurious. The citadel which defends the town coſt the French £.325,000 ſterling. The harbor here is one of the beſt in the Weſt-Indies, and the ſhips of war winter in it. —*ib.*

FORTUNE, a large bay towards the S. W. part of Newfoundland iſland; acroſs the mouth of which lies Micklon iſland, and S. of it Peters iſland. This extenſive bay is interſperſed with ſmall iſles, and within it are many bays. It has great depth of water throughout.—*ib.*

FOSSIL-Meal, otherwiſe called *lac lunæ*, mineral argaric, and guhr, is, according the M. Fabbroni, a mixed earth, which exhales an argillaceous odour, and throws out a light whitiſh ſmoke when ſprinkled with water. It is abundant in Tuſcany, where it is employed for cleaning plate. It does not effervesce with acids; is infuſible in the fire, in which it loſes an eighth part of its weight, though it becomes ſcarcely diminiſhed in bulk; and, according to the analyſis made by M. Fabbroni, conſiſts of the following component parts: ſiliceous earth 55, magneſia 15, water 14, argil 12, lime 3, iron 1. With this earth, which is found near Caſteldelpiano in the territories of Sienna, M. Fabbroni compoſed bricks, which, either baked or unbaked, floated in water. Hence he infers, that the floating bricks, which Pliny mentions as peculiar to Maſſilua and Calento, two cities in Spain, muſt have been made of foſſil-meal. Bricks made of that ſubſtance reſiſt water exceedingly well, and unite perfectly with lime; they are ſubject to no alteration either by heat or cold; and about a twentieth part of argil may be added with advantage to their compoſition, without depriving them of the property of floating. M. Fabbroni tried their reſiſtance, and found it very little inferior to that of common bricks; but it is much greater in proportion to their lightneſs. One of theſe bricks, ſeven inches in length, four and a half in breadth, and one inch eight lines in thickneſs, weighed only $14\frac{1}{4}$th ounces? whereas a common brick weighed 5 pounds $6\frac{3}{4}$ths ounces.

Bricks of foſſil-meal may be of important benefit in the conſtruction of reverberating furnaces, as they are ſuch bad conductors of heat, that a perſon may bring one half of them to a red heat, while the other is held in the hand. They may be employed alſo for buildings that require to be light; for conſtructing cooking places on board ſhips; and alſo floating batteries, the parapets of which, if made of theſe bricks, would be proof againſt red hot bullets; and, laſtly, for conſtructing powder magazines.

FOSTER, a townſhip in Providence co. Rhode-Iſland, containing 2268 inhabitants; 17 miles weſterly of Providence, and 31 N. W. of Newport.—*Morse.*

FOULAHS or Foolahs, a people in Africa, inhabiting a country on the confines of the great deſert (ſee Sahara in this *Suppl.*) along the parallel of nine degrees north. They partake much of the negro form and complexion; but have neither the *jetty* colour, *thick* lips, nor *criſped* hair of the negroes. They have alſo a language diſtinct from the Mandinga, which is the prevailing one in this quarter. The Foulahs occupy, at leaſt as ſovereigns, ſeveral provinces or kingdoms, interſperſed throughout the tract comprehended between the mountainous border of the country of Sierra Leona on the weſt, and that of Tombuctoo on the eaſt; as alſo a large tract on the lower part of the Senegal river; and theſe provinces are inſulated from each other in a very remarkable manner. Their religion is Mahomedaniſm; but with a great mixture of Paganiſm, and with leſs intolerance than is practiſed by the Moors.

The

The principal of the Foulah ſtates is that within Sierra Leona; and of which Teemboo is the capital. The next in order appears to be that bordering on the ſouth of the Senegal river, and on the Jaloffs; this is properly named Siratik. Others of leſs note are Bondou, with Foota-Torra adjacent to it, lying between the rivers Gambia and Falemé; Foola-doo and Brooko along the upper part of the Senegal river; Waſſela beyond the upper part of the Niger; and Maſſina lower down on the ſame river, and joining to Tombuctoo on the weſt.

The kingdom of the Foulahs, ſituated between the upper part of the Gambia river, and the coaſt of Sierra Leona, and along the Rio Grande, is governed by a Mahometan ſovereign; but the bulk of the people appear to be Pagans. From the circumſtances of their long hair, their lips, and comparatively light colour, Major Rennel is decidedly of opinion, that the Foulahs are the Leucæthiops of Ptolemy and Pliny. The former, as he obſerves, places the Leucæthiops in the ſituation occupied by the Foulahs; and by the name which he gave them, he evidently meant to deſcribe a people *leſs* black than the generality of the Ethiopians. Hence it may be gathered, that this nation had been traded with, and that ſome notices reſpecting it had been communicated to Ptolemy. It may alſo be remarked, that the navigation of Hanno terminated on this coaſt; and as this was alſo the term of Ptolemy's knowledge, it may juſtly be ſuſpected, that this part of the coaſt was deſcribed from Carthaginian materials.

Thoſe who have peruſed the journal of Meſſrs Watt and Winterbottom through the Foulah country in 1794, and recollect how flattering a picture they give of the urbanity and hoſpitality of the Foulahs, will be gratified on finding that this nation was known and diſtinguiſhed from the reſt of the Ethiopians at a remote period of antiquity.

The contraſt between the Mooriſh and Negro characters is as great as that between the nature of their reſpective countries, or between their form and complexion. The Moors appear to poſſeſs the vices of the Arabs without their virtues; and to avail themſelves of an intolerant religion, to oppreſs ſtrangers: whilſt the Negroes, and eſpecially the Mandingas, unable to comprehend a doctrine that ſubſtitutes opinion or belief for the ſocial duties, are content to remain in their humble ſtate of ignorance. The hoſpitality ſhewn by theſe good people to Mr Park, a deſtitute and forlorn ſtranger, raiſes them very high in the ſcale of humanity: and I know of no fitter title, ſays Mr Rennel, to confer on them than that of the *Hindoos of Africa*; at the ſame time, by no means intending to degrade the Mahomedans of India by a compariſon with the African Moors.—See *Major Rennel's Geographical Illuſtrations of Mr Park's Journey, and of North Africa at large*, printed for the African Aſſociation.

FOXBOROUGH, a townſhip in Norfolk co. Maſſachuſetts, containing 674 inhabitants, 26 miles S. of Boſton. It was formerly a part of Dorcheſter, and was incorporated in 1778.—*Morſe.*

FOX, a river in the N. W. territory, which riſes in the S. and runs about 50 miles N. where it approaches very near to, and parallel with, Ouiſconſin, a N. eaſtern branch of the Miſſiſſippi river. From the Great Carrying place here, through lake Winnebago, it runs eaſterly, then N. E. to bay Puan, about 180 miles. From the carrying place to Winnebago it is navigable for canoes 4 or 5 miles. From bay Puan its current is gentle; from thence to Winnebago lake it is full of rocks and very rapid. Its breadth is between 70 and 100 yards. The land on its borders is good, thinly wooded with hickory, oak, and hazel.—*ib.*

Fox, a northern water of Illinois river, 34 miles below the mouth of Plein river.—*ib.*

FRAMINGHAM, a townſhip in Middleſex co. Maſſachuſetts, containing 1598 inhabitants. It was incorporated in 1700, and is 24 miles W. S. W. of Boſton.—*ib.*

FRANCAIS (Port des), the name given by Perouſe to a bay, or rather harbour, which he undoubtedly diſcovered on the north-weſt coaſt of America. It is ſituated, according to him, in 58° 37. N. Lat. and in 139° 50′ W. Long. from Paris. When the two frigates which he commanded approached it, as they were ſtretching along the coaſt from ſouth to north, he perceived from his ſhip a great reef of rocks behind which the ſea was very calm. This reef appeared to be about three or four hundred toiſes in length from eaſt to weſt, and to be terminated, at about two cables length, by the point of the continent, leaving a pretty large opening; ſo that Nature ſeemed to have made, at the extremity of America, a harbour like that of Toulon, only more vaſt in her deſigns and in her means: this new harbour was three or four leagues deep.

Some officers, who had been diſpatched in boats to reconnoitre this harbour, gave a report of it extremely favourable; and on the 3d of July 1786, the two frigates entered it, and anchored near its mouth in three fathoms and a half, rocky bottom. The bay, however, was quickly ſounded, and much better anchoring ground diſcovered at an iſland in the middle of it, where the ſhips might ride in 20 fathoms water with muddy bottom. This ground was taken poſſeſſion of, an obſervatory erected on the iſland, which was only a muſket ſhot from the ſhips, and a ſettlement formed for their ſtay in the harbour. From a report made by one of the officers who had penetrated towards the bottom of the bay, Perouſe had conceived the idea of finding perhaps a channel by which he might proceed into the interior of America; but he was diſappointed. The bottom of the bay, indeed, according to him, is one of the moſt extraordinary places in the world. It is a baſon of water, of a depth in the middle that could not be fathomed, bordered by peaked mountains of an exceſſive height, covered with ſnow, without a blade of graſs upon this immenſe collection of rocks, condemned by Nature to perpetual ſterility. "I never (ſays he) ſaw a breath of air ruffle the ſurface of this water; it is never troubled but by the fall of enormous pieces of ice, which continually detach themſelves from five different glaciers and which in falling make a noiſe that reſounds far in the mountains. The air is in this place ſo very calm, and the ſilence ſo profound, that the mere voice of a man may be heard half a league off, as well as the noiſe of ſome ſea birds which lay their eggs in the cavities of theſe rocks."

It was at the extremity of this bay that he was in hopes of finding a paſſage into the interior of America. He imagined that it might terminate in a great river, of which the courſe might lie between two mountains;

Francais. and that this river might take its fource in the great lakes to the northward of Canada. Two channels were indeed found, ftretching, the one to the eaft, and the other to the weft; but both were very foon terminated by immenfe glaciers.

In Port des Français the variation of the compafs is 28° eaft, and the dip of the needle 74°. The fea rifes there feven feet and a half at full and change of the moon, when it is high water at one o'clock. The fea breezes, or perhaps other caufes, act fo powerfully upon the current of the channel, that M. Peroufe faw the flood come in there like the moft rapid river; while, in other circumftances, at the fame period of the moon, it may be ftemmed by a boat. In this channel he loft two fhallops and twenty men. In his different excurfions, he found the high water mark to be about 15 feet above the furface of the fea. Thefe tides are probably incident to the bad feafon. When the winds blow with violence from the fouthward, the channel muft be impracticable, and at all times the currents render the entrance difficult; the going out of it alfo requires a combination of circumftances, which may retard the departure of a veffel many weeks; there is no getting under way but at the top of high water; the breeze from the weft to the north-weft does not often rife till toward eleven o'clock, which does not permit the taking advantage of the morning tide; finally, the eafterly winds, which are contrary, appeared to him to be more frequent than thofe from the weft, and the vaft height of the furrounding mountains never permits the land breezes, or thofe from the north, to penetrate into the road.

As this port poffeffes great advantages, M. Peroufe thought it a duty incumbent on him to make its inconveniences alfo known. It feemed to him that this anchorage is not convenient for thofe fhips which are fent out at a venture for trafficking in fkins; fuch fhips ought to anchor in a great many bays, and always make the fhorteft ftay poffible in any of them; becaufe the Indians have always difpofed of their whole ftock in the firft week, and all loft time is prejudicial to the interefts of the owners; but a nation which fhould form the project of eftablifhing factories fimilar to thofe of the Englifh in Hudfon's Bay, could not make choice of a place more proper for fuch a fettlement. A fimple battery of four heavy cannon, placed upon the point of the continent, would be fully adequate to the defence of fo narrow an entrance, which is alfo made fo difficult by the currents. This battery could not be turned or taken by land, becaufe the fea always breaks with fuch violence upon the coaft, that to difembark is impoffible. The fort, the magazines, and all the fettlements for commerce, fhould be raifed upon Cenotaph Ifland (A), the circumference of which is nearly a league: it is capable of being cultivated, and there is plenty of wood and water. The fhips not having their cargo to feek, but being certain of having it collected to a fingle point, would not be expofed to any delay: fome buoys, placed for the internal navigation of the bay, would make it extremely fafe and eafy. The fettlement would form pilots, who, better verfed than we are in the fet and ftrength of the current at particular times of tide, would enfure the entrance and departure of the fhips. Finally, continues the author, our traffic for otters fkins has been fo very confiderable, that I may fairly prefume there could not, in any part of America, be a greater quantity of them collected.

The climate of this coaft feemed to Peroufe much milder than that of Hudfon's Bay in the fame latitude. Pines were meafured of fix feet diameter, and 140 high; while thofe of the fame fpecies at Prince of Wales's Fort and Fort York are of a dimenfion fcarce fufficient for ftudding fail-booms. Vegetation is alfo very vigorous during three or four months of the year; and our author thinks, that Ruffian corn, as well as many common plants might thrive exceedingly at Port des Français, where was found great abundance of celery, lupine, the wild pea, yarrow, and andive. Among thefe pot herbs were feen almoft all thofe of the meadows and mountains of France; fuch as the angelica, the butter cup, the violet, and many fpecies of grafs proper for fodder. The woods abound in goofeberries, rafpberries, and ftrawberries; clufters of elder trees, the dwarf willow, different fpecies of briar which grow in the fhade, the gum poplar tree, the poplar, the fallow, the horn-beam; and, finally, fuperb pines, fit for the mafts of our largeft fhips. Not any of the vegetable productions of this country are unknown in Europe. M. de Martinière, in his different excurfions, met with only three plants which he thought new; and it is well known, that a botanift might do the fame in the vicinity of Paris.

The rivers were filled with trout and falmon; and as the Indians fold thefe fifh to the French in greater quantities than they could confume, they had very little fifhing in the bay, and that only with the line. They caught fome ling, a fingle thornback, fome plaice, *fletans* or *faitans*, of which fome were more than 100 pounds in weight (B), and a fifh refembling the whiting, but a little larger, which abounds on the coaft of Provence, where it is known by the name of *poor-prieft*. Peroufe calls thefe fifh *capelans*. In the woods they met with bears, martens, and fquirrels; but they faw no great variety of birds, though the individuals were very numerous.

"If the animal and vegetable productions of this country refemble thofe of a great many others, its appearance (fays our author) can be compared to nothing. The views which it prefents are more frightful than thofe of the Alps and the Pyrenees; but at the fame time fo picturefque, that they would deferve the vifits of the curious, were they not at the extremity of the world. The primitive mountains of granite or fchiftus, perpetually covered with fnow, upon which are neither trees nor plants, have their foundation in the fea, and form upon the fhore a kind of quay; their flope is fo rapid, that after the firft two or three hundred toifes, the wild goats cannot climb them; and all the

(A) This name was given to the ifland in the bay from the monument erected on it to the memory of their unfortunate companions.

(B) This is a flat fifh, longer and not fo fquare as the turbet. Its back is covered with fmall fcales; and thofe which are taken in Europe are much lefs than the fletans of Port des Français.

Francais. the gullies which separate them are immense glaciers, of which the tops cannot be discerned, while the base is washed by the sea. At a cable's length from the land there is no bottom at less than 160 fathoms. The sides of the harbour are formed by secondary mountains, the elevation of which does not exceed from 800 to 900 toises; they are covered with pines, and overspread with verdure, and the snow is only seen on their summits: they appeared to be entirely formed of schistus, which is in the commencement of a state of decomposition; they are extremely difficult to climb, but not altogether inaccessible.

"Nature assigns inhabitants to so frightful a country, who as widely differ from the people of civilized countries as the scene which has just been described differs from our cultivated plains; as rude and barbarous as their soil is rocky and barren, they inhabit this land only to destroy its population: at war with all the animals, they despise the vegetable substances which grow around them. I have seen (says our author) women and children eat some raspberries and strawberries; but these are undoubtedly viands far too insipid for men, who live upon the earth like vultures in the air, or wolves and tigers in the forests.

"Their arts are somewhat advanced, and in this respect civilization has made considerable progress; but that which softens their ferocity, and polishes their manners, is yet in its infancy. The mode of life they pursue excluding all kind of subordination, they are continually agitated by fear or revenge; prone to anger, and easily irritated, they are continually attacking each other dagger in hand. Exposed in the winter to perish for want, because the chase cannot be successful, they live during the summer in the greatest abundance, as they can catch in less than an hour a sufficient quantity of fish for the support of their family; they remain idle during the rest of the day, which they pass at play, to which they are as much addicted as some of the inhabitants in our great cities. This gaming is the great source of their quarrels. If to all these destructive vices they should unfortunately add a knowledge of the use of any inebriating liquor, M. Perouse does not hesitate to pronounce, that this colony would be entirely annihilated."

Like all other savages, they are incorrigible thieves; and when they assumed a mild and placid appearance, the Frenchmen were sure that they had stolen something. Iron, of which they appeared to know the use, and of course the value, most excited their cupidity; and when our navigators were engaged in caressing a child, the father was sure to seize the opportunity of taking up, and concealing under his skin-garment, every thing of that metal which lay within his reach, and was not too heavy to be carried off.

M. Rollin, surgeon major of one of the frigates, thus describes these people. "They have very little similarity to the Californians; they are taller, stouter, of a more agreeable figure, and greater vivacity of expression: they are also much their superiors in courage and sense. They have rather a low forehead, but more open than that of the Southern Americans; their eyes are black and very animated; their eyebrows much fuller; their nose of the usual size, and well formed, except being a little widened at the extremity; their lips thinner; their mouth moderately large; their teeth fine and very even; their chin and ears very regular. Francais.

"The women also have an equal advantage over those of the preceding tribes; they have much more mildness in their features, and grace in their limbs—Their countenance would be even very agreeable, if, in order to set it off, they did not make use of a strange custom of wearing in the lower lip an elliptical piece of wood, lightly grooved on its circumference and both its sides, and which is commonly half an inch thick, two in diameter, and three in length.

"This singular ornament, besides being a great deformity, is the cause of a very troublesome as well as disgusting involuntary flow of saliva. This appendage is peculiar to the women; and female children are made to undergo the preparatory operations from the time of their birth. For this purpose, the lower lip is pierced with a kind of pin of copper or gold, which is either left in the opening, or its place supplied with a ring of the same material, till the period of puberty. The aperture is then gradually enlarged, by substituting first a small piece of wood of the form mentioned above, then a larger one; and so on, increasing its size by degrees till it reaches the dimensions just stated.

"This extraordinary custom shows the great power of dilatation in the lip, and may encourage medical practitioners in their attempts to remedy deformities of this part by the use of the knife.

"The general colour of these people is olive, a fainter tinge of which is apparent in their nails, which they suffer to grow very long; the hue of the skin, however, varies in different individuals, and in various parts of the same individual, according to their exposure to the action of the air and sun.

"Their hair is, in general, neither so coarse nor black as that of the South Americans. Chesnut coloured hair is by no means unfrequent among them. Their beard is also fuller, and their armpits and parts of sex better provided with hair.

"The perfect evenness of their teeth led me at first to suspect that it was the effect of art; but after an attentive and minute examination, I could perceive no wearing away of the enamel, and I saw that this regularity is natural. They tattoo and paint their face and body, and bore their ears and the cartilage of their nose.

"Some writers have imagined, that the custom of painting the face and body, so generally adopted by the Africans, Americans, and West-Indians, is only intended as a preservative against noxious insects. I think, however, that I am warranted in asserting its sole end to be ornament. I found it to prevail among the inhabitants of Easter Island and the natives of *Port des Français* without observing among them either venomous insects or reptiles. Besides, I remarked, that they wore paint only when they paid us a visit; for they made no use of it when in their own houses."

M. Perouse himself speaks not so favourably of the women as M. Rollin. "They are (he says) the most disgusting of any on the earth, covered with stinking skins, which are frequently untanned; and yet they failed not to excite desires in some persons, in fact of no small consequence: they at first started many difficulties, giving assurances by their gestures that they ran the risk of their lives; but being overcome by presents,

ſents, they had no objection to the ſun being a witneſs, and abſolutely refuſed to retire into the wood." There can be no doubt that this planet is the god of theſe people, ſince they frequently addreſſed themſelves to it in their prayers; but our voyagers ſaw neither temple nor prieſt, nor the leaſt trace of public worſhip at ſtated times. They burn their dead.

FRANCESTOWN, an interior townſhip in Hillſborough co. New-Hampſhire, on the E. ſide of Contecook river, about 21 miles to the S. W. of Concord. It was incorporated in 1772, and contained in 1775, 200 inhabitants, in 1790, 982.—*Morſe.*

FRANCISBOROUGH, a ſettlement in York co. diſtrict of Maine, containing 311 inhabitants.—*ib.*

FRANCIS, St a lake, or extenſion of the river St Lawrence, between Kingſton and Montreal, through which paſſes the line dividing Upper from Lower Canada.—*ib.*

Francis, St a river in the province of Lower Canada, which riſes from lake Memphremagog, and runs northward into the river St Lawrence. It is not all the way navigable; elſe it would afford an important communication from the northern parts of Vermont to the markets of Montreal and Quebec.—*ib.*

Francis, St a ſmall river in Louiſiana, which runs a S. E. courſe into the Miſſiſſippi, 108 miles above Arkanſas river, and 70 miles above Margot river, on the E. ſide of the Miſſiſſippi. It is remarkable for nothing but the general rendezvous for the hunters from New-Orleans, who winter there, and collect ſalt meat, ſuet, and bear's oil, for the ſupply of that city. Kappas Old fort formerly ſtood at the mouth of this river, on the ſouthern ſide. It was built by the French during their wars with the Chickaſaw Indians.

Alſo, the name of a ſmall river in the N. W. territory, which runs a S. W. by W. courſe into Miſſiſſippi, between Cold and Rum rivers, 60 miles above St Anthony's Falls. The country a little above it is hilly, and the ſoil pretty good. To the N. E. are the ſmall lakes called the Thouſand lakes. The Miſſiſſippi here is not above 90 yards wide.—*ib.*

Francis, St in Brazil, S. America, a long and large river which runs N. eaſterly, and thence S. E. till it empties into the ocean, N. E. of the town of Seregeppe del Rey. It has a number of towns and ſettlements, chiefly on its head waters.—*ib.*

FRANCOIS, Cape St a juriſdiction, city, and port in the N. weſtern part of the iſland of St Domingo. This juriſdiction is in the North diviſion of the iſland, in what was called the French part of it; and contains 13 pariſhes. Its exports from Jan. 1, 1789, to Dec. 31, of the ſame year, were as follow: 31,187,636lb. white ſugar, 7,267,531lb. brown ſugar, 32,545,524lb. coffee, 269,240lb. cotton, 245,177lb. indigo; tanned hides, molaſſes, ſpirits, &c. to the value of 21,789 livres. Total value of duties on exportation, 253,590 dollars, 37 cents. Cape François exceeds Port au Prince in the value of its productions, the elegance of its buildings, and the advantageous ſituation of its port. The city, which is the governor's reſidence in time of war, is ſituated on a cape at the edge of a large plain, 20 leagues long, and on an average 4 broad, between the ſea and the mountains. There are few lands better watered, but there is not a river that will admit a ſloop above 3 miles. This ſpace is cut through by ſtraight roads, 40 feet broad, uninterruptedly lined with hedges of lime and lemon trees, intermixed with long avenues of lofty trees, leading to plantations which produce a greater quantity of ſugar than any ſpot of the ſame ſize in the world. The town, which is ſituated in the moſt unhealthy place of this extenſive and beautiful plain, had, ſome years ſince, ſeveral elegant public buildings, as the governor's houſe, the barracks, the magazine, and two hoſpitals, called the *houſes of Providence*, founded for the benevolent and humane purpoſe of ſupporting thoſe Europeans who came thither without money or merchandize. The harbour is admirably well ſituated for ſhips which come from Europe, being only open to the N. from whence ſhips receive no damage, its entrance being ſprinkled over with reefs that break the force of the waves. Before its deſtruction in 1793, this city contained about 8000 inhabitants; whites, people of colour, and ſlaves.—*ib.*

Francois, Old Cape, the north-eaſternmoſt point of the iſland of St Domingo or Hiſpaniola; having Balſamo bay N. W. and Scotch bay S. S. E.—*ib.*

FRANCONIA, a townſhip in Grafton co. New-Hampſhire, 14 miles N. E. of Haverhill (N. H.) on Connecticut river. Incorporated in 1764, firſt called Morriſtown. It contains 72 inhabitants.—*ib.*

FRANKFORT, a townſhip in Hancock co. diſtrict of Maine, on the W. ſide of Penobſcot bay. It has a few houſes, regularly built, and lies 8 miles W. of Penobſcot, 123 W. of Paſſamaquoddy, and 238 N. E. of Boſton. The townſhip contains 891 inhabitants.—*ib.*

Frankfort, or *Frankford*, a pleaſant, thriving village, in Philadelphia co. Pennſylvania, ſeated on the N. E. ſide of a creek of the ſame name, a mile and an half from Delaware river. It contains about 50 houſes, chiefly of ſtone, an Epiſcopal and a German church; on elevated ground, about 5 miles N. E. of Philadelphia.—*ib.*

Frankfort, a new townſhip in Herkemer co. New-York, E. of Whiteſtown, adjoining.—*ib.*

Frankfort, a thriving village in Hampſhire co. Virginia, on a creek which empties into Potowmack river. It is 13 miles N. W. of Rumney, 4 miles S. of the Potowmack, and 10 S. S. E. of Fort Cumberland.—*ib.*

Frankfort, the capital of Pendleton co. Virginia, is ſituated on the W. ſide of a S. branch of Potowmack river. It contains a court-houſe, gaol, and about 30 houſes; 180 miles N. W. of Richmond.—*ib.*

Frankfort, the metropolis of Kentucky, is ſituated in Franklin co. on the N. E. bank of Kentucky river, about 50 miles from its confluence with the Ohio. It is a flouriſhing town, regularly laid out, and has a number of handſome houſes. The ſtate houſe is a handſome ſtone building. Here is alſo a tobacco warehouſe. It is 30 miles N. of Harrodſburg, 40 N. by W. of Danville, 125 from Louiſville, and 790 W. by S. of Philadelphia. N. lat. 38. 14. W. long. 95. 28.—*ib.*

FRANKLIN (Dr Benjamin), the celebrated American philoſopher and ſtateſman, was born at Boſton in 1706 of reſpectable, but not wealthy parents. The promptitude with which, from his infancy, he had learned to read was ſuch, that he ſaid he did not remember to have been ever without this acquirement.

At eight years of age he was sent to a grammar school, his father having intended him for the church, but contemplating the expence of a collegiate education, recalled him, within a year, and sent him to learn arithmetic and writing: he soon wrote well, but made no progress in arithmetic. At ten he was called home to assist his father in his business of soap boiler and tallow chandler, a business which he disliked, and two years afterwards was bound apprentice to his brother who was a printer. In this employment he made great proficiency, and having access to more books than formerly, he devoted much of his leisure time to reading. He acknowledged that the perusal of Shaftesbury and Collins made him a sceptic completely, having been previously so with respect to many doctrines of christianity, and that he found the Socratic mode of reasoning enabled him to embarrass even persons of superior understanding, and to obtain for him victories which neither his cause nor his arguments merited. During his apprenticeship he wrote several pieces for the newspaper which were approved, but kept himself unknown. After frequent disputes with his brother, he determined to leave Boston, where in consequence of his indiscreet disputes about religion he had begun to be looked upon by pious men with horror as an apostate or an atheist. He privately got on board a sloop and soon arrived in New-York, where he applied for employment to Mr Bradford, who could not employ him, but advised him to go to Philadelphia, where after a very unpleasant and dangerous journey he at last arrived, and with some difficulty got employment with one Keimer, with whom he continued for some time, till by the advice of Sir William Keith, then governor of Pennsylvania, he sailed for England, where he arrived in 1724. Disappointed by not having letters of recommendation from the governor, he applied for and obtained employment as a journeyman Printer, where he improved his knowledge and saved some money. Here he published his Dissertation on Liberty and necessity, and associated with Lyons, Mandeville and others of that class. After nearly two years residence in London he returned to Philadelphia with a Mr Denham as his clerk and assistant in a store. On Mr Denham's death Franklin returned to Keimer in capacity of foreman, which continued with little interruption till he set up a printing-office himself. In this period of the history of his life written by himself he gives the following statement of his principles.

"Before I relate the particulars of my entrance into business, it may be proper to inform you what was at that time the state of my mind as to moral principles, that you may see the degree of influence they had upon the subsequent events of my life.

My parents had given me betimes religious impressions; and I received from my infancy a pious education in the principles of Calvinism. But scarcely was I arrived at fifteen years of age, when, after having doubted in turn of different tenets, according as I found them combated in the different books that I read, I began to doubt of revelation itself. Some volumes against deism fell into my hands. They were said to be the substance of sermons preached at Boyle's lecture. It happened that they produced on me an effect precisely the reverse of what was intended by the writers; for the arguments of the deists, which were cited in order to be refuted, appeared to me much more forcible than the refutation itself. In a word, I soon became a perfect deist. My arguments perverted some other young persons; particularly Collins and Ralph. But in the sequel, when I recollected that they had both used me extremely ill, without the smallest remorse; when I considered the behaviour of Keith, another freethinker, and my own conduct towards Vernon and Miss Read, which at times gave me much uneasiness, I was led to suspect that this doctrine, though it might be true, was not very useful. I began to entertain a less favourable opinion of my London pamphlet, to which I had prefixed, as a motto, the following lines of Dryden;

> Whatever is, is right; tho' purblind man,
> Sees but part of the chain the nearest link,
> His eyes not carrying to the equal beam
> That poises all above.

and of which the object was to prove, from the attributes of God, his goodness, wisdom, and power, that there could be no such thing as evil in the world; that vice and virtue did not in reality exist and were nothing more than vain distinctions. I no longer regarded it as so blameless a work as I had formerly imagined; and I suspected that some error must have imperceptibly have glided into my argument, by which all the inferences I had drawn from it had been affected as frequently happens in metaphysical reasonings. In a word, I was at last convinced that truth, probity, and sincerity, in transactions between man and man, were of the utmost importance to the happiness of life; and I resolved from that moment, and wrote the resolution in my journal, to practise them as long as I lived.

Revelation indeed, as such, had no influence on my mind; but I was of opinion that, though certain actions could not be bad merely because revelation prohibited them, or good because it enjoined them, yet it was probable that those actions were prohibited because they were bad for us, or enjoined because advantageous in their nature, all things considered. This persuasion, Divine Providence, or some guardian angel, and perhaps a concurrence of favourable circumstances co-operating, preserved me from all immorality, or gross and *voluntary* injustice, to which my want of religion was calculated to expose me, in the dangerous period of youth and in the hazardous situations in which I sometimes found myself, among strangers, and at a distance from the eye and admonitions of my father. I may say *voluntary*, because the errors into which I had fallen, had been in a manner the forced result either of my own inexperience, or the dishonesty of others. Thus, before I entered on my new career, I had imbibed solid principles, and a character of probity. I knew their value; and I made a solemn engagement with myself never to depart from them."

He now began business in partnership with Mr Meredith which lasted till 1729, when Franklin took the whole business into his own hands. In the mean time he had united the majority of well informed persons of his acquaintance into a club, known by the name of the *Junto*, for the purpose of mutual improvement, which met every Friday evening to consider questions of morality, politicks, or philosophy, which became a very useful institution and which continued almost forty years. On entering into buſineſs by himſelf he found himſelf in embarraſſed circumſtances from which he was relieved by the generous aſſiſtance of William Coleman and Robert Grace, whoſe kindneſs made a deep impreſſion on his mind. He now opened a ſmall ſtationer's ſhop, was induſtrious, ſteady, and ſucceſsful, and in 1730 he married the daughter of Mr Read, who was now a widow. Having had frequent occaſion to quote books in the club, he ſtarted the idea of eſtabliſhing a public library, which was carried into effect in 1731 and became the foundation of that noble inſtitution which was incorporated in 1742, and now does honour to the city of Philadelphia. This inſtitution was greatly encouraged by the friends of literature in America and in Great Britain. The Penn family diſtinguiſhed themſelves by their donations, and the late Peter Collinſon, beſides liberal donations from himſelf and obtained from others, voluntarily undertook to manage the buſineſs of the company in London for which his extenſive knowledge and zeal for the promotion of ſcience eminently qualified him, recommending ſuitable books, purchaſing, and ſhipping them for thirty years, which he communicated to the directors every improvement and diſcovery in the arts, agriculture and philoſophy.

In 1732 Franklin began to publiſh Poor Richard's Almanack, remarkable for numerous and valuable conciſe maxims, tending to promote induſtry, and frugality: the demand for it was ſuch that 10,000 have been ſold in one year. Theſe maxims have been collected in an addreſs entitled, The Way to Wealth, which has appeared in various publications.

In 1736 Franklin was choſen clerk to the General Aſſembly of Pennſylvania, and in 1737 he was appointed poſt-maſter: in 1738 he formed the firſt Fire Company in Philadelphia, and ſome time after ſuggeſted the plan of an aſſociation for inſuring houſes from loſs by fire, which has been a very valuable inſtitution.

In 1744 during a war between France and Britain, ſome French and Indians had made inroads upon the frontiers of Pennſylvania, whoſe inhabitants were unprovided for ſuch an attack. The governor recommended to the Aſſembly to paſs a militia law, but owing to ſome diſputes between the governor and Aſſembly it was not done, the ſituation of the Province was alarming, and deſtitute of the means of defence. At this criſis Franklin ſtepped forth and propoſed to a meeting of the citizens of Philadelphia, a voluntary aſſociation for the defence of the Province. This was approved of and ſigned by 1200 perſons immediately, and in a ſhort time the number increaſed to 10,000. Franklin was choſen colonel of the Philadelphia regiment but choſe to decline the honour.

In the year 1745 Mr Collinſon ſent to the Library Company of Philadelphia an account of the experiments in electricity which had at that time engaged the attention of the philoſophers in Europe. Mr Kinnerſley and others applied themſelves to the ſubject, and Franklin ſoon made a diſtinguiſhed figure in this courſe, his experiments and diſcoveries are ſo numerous, and ſo well known as to render an account of them in this place ſuperfluous. The practical uſe of his diſcoveries in the application of pointed conductors for the purpoſe of ſecuring houſes from injury by lightning is well known and in general uſe in America, and in many places in Europe.

In 1747 he became a member of the General Aſſembly of Pennſylvania, where his influence was very conſiderable. He ſeldom ſpoke, and never attempted oratory, but frequently by a ſingle obſervation determined the fate of a queſtion. Perceiving that the beſt way of ſecuring permanently the rights of the people was, by the general diffuſion of knowledge and information to all claſſes, he drew up a plan of an Academy to be erected in the city of Philadelphia, not only adapted to an infant colony, but alſo as a foundation on which poſterity might erect a more extenſive ſeminary. The conſtitution was drawn up and ſigned in 1749, and in 1750 the Latin and Greek, Mathematical and Engliſh ſchools were opened, and a Charity ſchool for 60 boys and 30 girls. This inſtitution was incorporated in 1753, and an additional charter was obtained in 1755. In 1752 he had joined in the ſcheme ſuggeſted by Dr Bond, and on application to the Aſſembly obtained from the public £.2000 for eſtabliſhing the Hoſpital for the poor when viſited by diſeaſe. In 1753 he was appointed deputy poſt-maſter general for the Britiſh Colonies, and in his hands this department was ſo well adminiſtered that its annual produce was ſaid to be more than double that of Ireland.

In 1754 Franklin, as commiſſioner from Pennſylvania, met at Albany with the commiſſioners of ſeveral of the other colonies, and produced a plan which has been called the Albany Plan of Union for the defence and general government of the colonies. After ſeveral days diſcuſſion it was unanimouſly agreed to, and a copy of it tranſmitted to each colonial Aſſembly, and one to the king's Council. The fate of it was ſingular: it was rejected by the miniſtry of Great Britain, becauſe it gave too much power to the repreſentatives of the people, and it was rejected by all the aſſemblies as giving to the preſident general, the repreſentative of the Crown, an influence greater than appeared to them proper in a plan of government intended for freemen.

The defeat of Braddock ſpread a very great alarm through the colonies. Franklin introduced into the Aſſembly a bill for organizing a militia, the bill paſſed and he was appointed colonel of a regiment in Philadelphia of 1200 men; the frontier being invaded, he repaired by order of the governor, with a body of men, to the place at which their preſence was neceſſary, built a fort, and placed a garriſon in ſuch a poſture as to withſtand the inroads to which the inhabitants had been expoſed. In 1757 he was appointed agent for the province of Pennſylvania to preſent to the king a petition for redreſs from the attention of the proprietaries to their private intereſt, who would not conſent that their eſtates ſhould be taxed to bear a ſhare of the public burdens. Agreeably to the inſtructions which he had received from the legiſlature he endeavoured to prevail on the proprietaries to give up the point in conteſt, finding them obſtinate, he laid his petition before the council, where after much oppoſition it was agreed that the proprietary eſtates ſhould pay their due proportion of taxes on Mr Franklin engaging that their burdens ſhould not exceed the due proportion. After tranquillity had been re-eſtabliſhed by his abilities and integrity as agent for Pennſylvania, his extensive knowledge of the situation of the colonies occasioned his appointment as agent for Massachusetts, Maryland, and Georgia, in which situation his conduct rendered him dear to his countrymen. He had now the rewards of literary and philosophical merit abundantly bestowed on him, by being admitted fellow of many learned societies. The degree of Doctor of Laws was conferred on him by the Universities of St Andrews, Edinburgh, and Oxford, and his correspondence sought for by the most eminent philosophers of Europe. During this period he shewed in a pamphlet the advantages which would accrue from the conquest of Canada, which was shortly after accomplished. He continued his philosophical researches and experiments with great success, and after a variety of experiments on Mr Puckeridge's discoveries he formed that elegant instrument which he called the Harmonica, and in his return in 1762, observed the effect of oil on the surface of the ocean.

Having received the thanks of the Assembly of Pennsylvania, and a vote of £.5000 for his services, he resumed his seat as a member of that body, with as much popularity as before.

In 1764 he was again sent to London as provincial agent, and in 1766 was examined at the bar of the House of Commons respecting the repeal of the stamp act. The same year he visited Holland and Germany, where he was well received by men of science, as he was also in France in the following year. Several letters from Hutchinson, Oliver and others came into the hands of Dr Franklin, containing violent invectives against the leading characters in Massachusetts, and strenuously advising vigorous measures to compel the people to obedience, these he sent to the legislature, by whom they were published, attested copies were sent to Great Britain, with a petition to the king to remove the writers from office. Dr Franklin declared that he had sent the letters, but refused to give information of the manner in which they came to his hands; the petition was rejected. The measures which the ministry pursued in laying taxes on the colonies Dr Franklin used his utmost endeavours to induce them to change but without success, and finding all his efforts to restore harmony useless he returned to America in 1775. Just after the commencement of hostilities, he visited Canada to persuade the citizens to join in the common cause, but did not succeed. In 1776 he was joined with Mr Adams and Mr Rutledge to learn the extent of the powers of those commissioners who came with Lord Howe, but finding that they were only empowered to grant pardons on submission, nothing could be done. He gave his voice decidedly for independence, and had great influence in bringing over others to the same views. The public mind had been in some measure prepared for this by Paine's pamphlet *Common Sense*: there was good reason to believe that Dr Franklin had a considerable share in this work. The same year he was chosen president of the Convention which met in Philadelphia to form a new constitution for Pennsylvania. In the latter end of the year he was appointed to assist in the negociations which had been set on foot in France by Silas Deane, but nothing could be accomplished till the news of the capture of Burgoyne's army by the Americans decided the conduct of France: to this also was owing the facility with which loans in Holland and France were negociated. He was one of those who signed the provisional articles of peace in Nov. 1782, and the definitive treaty on the 30th September 1783. He was one of the commissioners appointed to examine Mesmer's Animal Magnetism in 1784. In 1785 he arrived in Philadelphia, where he was chosen member of the supreme executive council, and shortly afterward was elected President of it.

In 1787 he was appointed delegate for Pennsylvania in the grand convention and signed the constitution of the United States. He was a member of several political and benevolent societies. His infirmities increasing prevented his regular attendance in the council chamber, and in 1788 he retired from public life. He was attacked with a calculous complaint in 1781 which continued to his death, which took place on the 17th of April 1790, at the age of Eighty-four years and three months.

The following epitaph on him, was written by himself many years previous to his death;

THE BODY
of
Benjamin Franklin, Printer,
(Like the cover of an old book,
Its contents torn out
And stript of its lettering and gilding)
Lies here food for worms;
Yet the work itself shall not be lost,
For it will (as he believed) appear once more,
In a new
And more beautiful edition,
Corrected and amended
by
The Author.

Franklin, Fort, is in Alleghany co. Pennsylvania, near the post called Venango, and was erected in 1787 in order to defend the frontiers of Pennsylvania from the depredations of the neighbouring Indians. It is seated on the S. W. bank of Alleghany river, opposite the mouth of French creek. N. lat. 41. 1. 40. W. long. 79. 41.; 53 miles S. S. E. of Presque Isle, and 63 northward of Pittsburg.—*Morse.*

Franklin *Co.* the north-westernmost in Vermont, bounded N. by Lower Canada, and W. by lake Champlain. It was lately taken from Chittenden co. and contains 20 townships.—*ib.*

Franklin *Co.* in Pennsylvania, bounded N. by Mifflin, N. E. by Cumberland, E. by York, S. by Washington co. in Maryland, W. by Bedford co. and N. W. by Hunterdon. It is computed to contain 800 square miles, equal to 512,000 acres. It lies chiefly between the N. and S. Mountains, and comprehends the middle part of the beautiful and rich valley of Conegocheague; which is watered by the creek of its name, which falls into Potowmack at Williams Port in Maryland. This county exhibits a most luxuriant landscape in summer, from the top of South Mountain. Iron ore is found here sufficient already to furnish work for a furnace and forge. The county is divided into 11 townships, which contain 15,655 inhabitants, of whom 330 are slaves.—*ib.*

Franklin *Co.* in Kentucky, is bounded N. by Scott co.

co. N. W. and W. by Shelby, S. E. by Fayette, and S. by Woodford. Chief town, Frankfort.—*ib.*

FRANKLIN *Co.* in Halifax district, N. Carolina, contains 7559 inhabitants, of whom 2717 are slaves. It is bounded N. by Greenville, S. by Johnston, N. E. by Warren, S. W. by Wake, and W. by Orange co. Chief town, Lewisburg.—*ib.*

FRANKLIN *Co.* in Virginia, is bounded N. by Bedford, N. W. by Botetourt, W. by Montgomery, S. W. by Henry, S. by Patrick, and E. by Campbell co. It is about 40 miles long, and 25 broad, and contains 6842 inhabitants, including 1073 slaves. A range of the Alleghany Mountains passes through it on the N. W. It is consequently hilly in general.—*ib.*

FRANKLIN *Co.* in Georgia, is situated in the Upper District, bounded E. and N. E. by Tugulo river, which separates it from the state of S. Carolina; W. and N. W. by the country of the Cherokees; S. by the head branches of Broad river, and S. E. by Elbert co. It contains 1041 inhabitants, of whom 156 are slaves. The court-house is 17 miles from Hatton's Ford on Tugulo river, 25 from Elberton, and 77 from Washington.—*ib.*

FRANKLIN, a township in Norfolk co. Massachusetts; taken from Wrentham, and incorporated in 1778, and contains 17,000 acres of land. It has 1101 inhabitants; is bounded N. by Charles river, which separates it from Medway, and lies 30 miles S. of Boston.—*ib.*

FRANKLIN, a small isle at the mouth of St George's river in Lincoln co. Maine; 4 leagues southward of Thomaston.—*ib.*

FRANKLIN, a new township in Dutchess co. New-York. By the state census of 1796, it appears there are 210 of its inhabitants qualified to be electors.—Also, a new township in Delaware county, of whose inhabitants 239 are electors. It lies S. W. from, and borders on Harpersfield, and its W. line runs along the S. eastern bank of Susquehanna river. This town was divided by an act of the Legislature, 1797.—*ib.*

FRANKLIN, a township in Westmoreland co. Pennsylvania.—Also, 3 others in the same state, viz. in York co. Fayette co. and in Washington co.—*ib.*

FRANKLIN, a township, the northernmost in New-London co. Connecticut, 6 miles N. W. of Norwich. It contains above 1000 inhabitants, who are chiefly wealthy farmers.—*ib.*

FRANKSTOWN, a township in Huntingdon co. Pennsylvania, situated on the Frankstown branch of Juniatta river, 20 miles W. of Huntingdon.—*ib.*

FRAYLES, an island near the coast of New-Andalusia, Terra Firma.—*ib.*

FREDERICA, a village in Kent co. state of Delaware, situated between the two main branches of Mother Kill, a stream which falls into Delaware 7 miles from the town, and 3 S. E. of Jame's creek, which leads up to Dover. It contains about 40 houses, and lies 12 miles E. of Dover, and 88 from Philadelphia.—*ib.*

FREDERICA, a town of Glynn co. in Georgia, is situated on St Simon's island, in a very pleasant situation, and was built by General Oglethorpe. The fortress was beautiful and regular, but is now in ruins. The town contains but few houses, which stand on an eminence, upon a branch of Alatamaha river, which washes the W. side of this agreeable island, and forms a bay before the town, affording a safe and commodious harbor for vessels of the largest burden, which may lie along the wharf. It was settled by some Scotch highlanders, about the year 1735, who accepted of an establishment both here and at Darien, to defend the colony, if needful, against the neighbouring Spaniards. N. lat. 31. 15. W. long. 80.—*ib.*

FREDERICK *Co.* in Maryland, is bounded N. by Pennsylvania, W. and N. W. by Washington, E. by Baltimore, and S. W. by Potowmack river. On the Monocacy river and its branches are about 37 gristmills, a furnace, iron forge, and a glass manufactory, called the Etna glass works, which are in a thriving state. This county is about 30 miles each way, reckoning from the extreme parts. The Cotoctiny Mountain extends from the Potowmack in a N. direction through this county into Pennsylvania, between the South Mountain and Monocacy Creek; the eastern parts are generally level. It contains 30,791 inhabitants, including 3,641 slaves. Chief town, Frederick-town.—*ib.*

FREDERICK *Co.* in Virginia, is bounded N. by Berkley, S. by Shanandoah, W. by Hampshire, and E. by Shanandoah river, which separates it from Loudon co. It is 30 miles in length, and 20 in breadth, and contains 19,681 inhabitants, of whom 4,250 are slaves. Iron ore is found here in great plenty; and works have been erected which produce 160 tons of bar iron, and 650 tons of pig, annually. In one year 300 tons of bar iron were manufactured. Pots and other utensils, cast thinner than usual of this iron, may be safely thrown into or out of the waggon, in which they are transported. Both this and Berkley co. has a good soil. Between the waters of Opeckan creek and the Shanandoah is the richest limestone land in the eastern parts of the state.

Near the North Mountain in this county is a curious cave, by some called *Zancy's Cave*. Its entrance is on the top of an extensive ridge. You descend 30 or 40 feet as into a well, from whence the cave then extends, nearly horizontally, 400 feet into the earth, preserving a breadth of from 20 to 50 feet, and a height of from 5 to 12 feet. After entering this cave a few feet, the mercury, which, in the open air, was at 50. rose to 57. of Fahrenheit's thermometer. After this may be added the Natural Well on the lands of Mr. Lewis. It is somewhat larger than a common well, and rises as near the surface of the earth as in the neighbouring artificial wells; and is of a depth, as yet unknown. It is used with a bucket and windlass as an ordinary well. It is said there is a current in it tending sensibly downwards. Chief town, Winchester.—*ib.*

FREDERICK *House*, a trading station in Upper Canada, on the head water of Abbitibbe river. N. lat. 48. 35. W. long. 82. 6.—*ib.*

FREDERICK, a fort in Washington co. Maryland, situated on the N. E. bank of Potowmack river, near the S. line of Pennsylvania.—*ib.*

FREDERICK, a towship in Montgomery co. Pennsylvania.—*ib.*

FREDERICK, a town on the N. side of Sassafras river, in Cecil co. Maryland, and separated by that river from George Town in Kent co. It lies 6 miles S. W. of Warwick, and 14 E. of Grove point in Chesapeak bay. N. lat. 39. 22. 30.—*ib.*

FREDERICKSBURG, a post town in Spotsylvania co. Virginia; situated on the S. W. bank of Rappahannock river, 110 miles from its mouth in Chesapeak bay. It is an incorporated town, and regularly laid out into several streets, the chief of which runs parallel with the river, and in all contains upwards of 200 houses, two tobacco warehouses, and several stores of well assorted goods. Its public buildings are an Episcopal church, an academy, court-house and gaol. It is a place of considerable trade and contains about 2000 inhabitants, of whom 587 are slaves. A forge in this neighborhood made, sometime ago, about 300 tons of bar iron in a year, from pigs imported from Maryland. It is 50 miles S. S. W. of Alexandria, 68 N. by E. of Richmond, 102 S. W. of Baltimore, and 205 S. W. of Philadelphia. N. lat. 38. 22. W. long 77. 36.—*ib.*

FREDERICKSTOWN, a township in Dutchess co. New-York, which contains 5932 inhabitants, of whom 188 are qualified to be electors, and 63 are slaves.—*ib.*

FREDERICKTON, a considerable township in the province of New-Brunswick, 90 miles up St John's river, which is thus far navigable for sloops.—*ib.*

FREDERICKTOWN, a post town of Maryland, and capital of Frederick co. situated on both sides of Carrolls' creek, a small stream that empties into Monocacy river over which are two bridges. The streets are regularly laid out, intersecting each other at right angles. The dwelling-houses, chiefly of stone and brick, are about 700 in number, many of which are handsome and commodious. The public edifices are, one church for Presbyterians, two for German Lutherans and Calvinists, and one for Baptists, an elegant court-house, a gaol, and a brick market-house. It is a very flourishing town, and has considerable trade with the back country. The Etna glass works are situated 4 miles above the town, on Tuskarora creek. Fredericktown is 4 miles E. of Cotoctin mountain, 47 W. by N. of Baltimore, 24 E. of Sharpsburg, and 148 S. W. by W. of Philadelphia, N. lat. 39. 24.—*ib.*

FREEHOLD, a town in Monmouth co. New-Jersey, 15 miles W. of Shrewsbury, and 20 S. E. by S. of New-Brunswick. In this town was fought the obstinate battle called the Monmouth battle, on the 28th of June, 1778. There is an academy in this town. Freehold contains 3785 inhabitants, of whom 627 are slaves.—*ib.*

FREEHOLD, a township in Albany co. New-York, containing 1822 inhabitants, of whom 562 are qualified electors, and 5 are slaves.—*ib.*

FREEPORT, a township in Cumberland co. district of Maine, situated at the head of Casco bay; adjoining to Durham on the N. E. and to North Yarmouth on the S. W.; about 10 miles N. E. of Portland, and 140 N. by E. of Boston. It was incorporated in 1789, and contains 1330 inhabitants.—*ib.*

FREESTONE-GAP, a place so called, in Tennessee, 25 miles from Hawkin's court-house, and 35 from Cumberland mountain.—*ib.*

FREETOWN, a thriving township in Bristol co. Massachusetts, incorporated in 1683, contains 2202 inhabitants, and lies 50 miles southerly of Boston.—*ib.*

FRE'GATES FRANÇAISE *Basse de*, the name given by La Perouse to a dangerous reef of sunken rocks which he discovered in the Pacific ocean. On the north-west extremity of this reef they perceived an islet or split rock from 20 to 25 fathoms in height and about 50 toises in diameter. From this islet the reef extends more than four leagues to the south-east; and upon the extremity of the point in that direction, the frigates had almost struck before the breakers were observed. This was during a fine clear night and smooth sea. With great propriety, the Commodore returned in the morning to ascertain the geographical situation of this unknown rock; and he estimated the islet to be in 23° 45′ N. Lat. and 168° 10′ W. Long. from Paris.

FRENCH, a small river in Massachusetts, has its source in a small pond, on the borders of Leicester and Spencer, in Worcester co. and runs through Oxford and joins Quinebauge river, in Thompson township, in Connecticut. It derives its name from the French Protestants, who obtained a settlement in the town of Oxford, after the revocation of the edict of Nantz, in 1685.—*Morse.*

FRENCH BROAD, a navigable river in Tennessee, which rises on the S. E. side of the Great Iron and Bald mountains, in N. Carolina. It is formed by two main branches, which receive several streams in their course. These unite about 58 miles from the source of the Nolachucky, the eastern branch; thence it flows N. westerly about 25 miles, and joins the Holston 11 miles above Knoxville, and is 400 or 500 yards wide. The navigation of this branch is much interrupted by rocks, as is also the Tennessee branch, which joins the main river 50 miles below this.

A large, clear, medicinal spring, said to be efficacious in curing many diseases, has been lately discovered on the waters of this river, about 30 miles in a direct line from its mouth. The water is so hot, that a patient at first going into it can scarcely support it. Nearer the mouth of the river, a valuable lead mine has been discovered.—*ib.*

FRENCH *Creek*, a N. western water of Alleghany river, into which it falls along the N. side of Fort Franklin, 80 miles N. by E. of Pittsburg. It affords the nearest passage to lake Erie. It is navigable with small boats to Le Beuf, by a very crooked channel; the portage thence to Presque Isle, from an adjoining peninsula, is 15 miles. This is the usual route from Quebec to Ohio.—*ib.*

FRENCH *Lick*, in Tennessee, is the name of a salt spring, near which the town of Nashville now stands. —*ib.*

FRENCH *Town*, in Cecil co. Maryland, lies on the E. side of Elk river, a mile S. of Elkton, from which it is separated by Elk creek. Elk ferry is 6 miles below this.—*ib.*

FRENCHMAN'S *Bay*, lies on the sea coast of Lincoln co. Maine, and is formed by Mount Desert island on the westward, and the peninsula of Goldsborough township on the eastward —Round Mount Desert island it has an inland circular communication with Blue Hill bay.—*ib.*

FRENEUSE *Lake*, a large collection of water, through which St John's river in New-Brunswick, passes. In some maps this appears only as a dilatation of the river; but in others it appears as a large lake of very irregular figure, and receiving considerable streams from the circumjacent country.—*ib.*

Friction.

FRICTION, in mechanics, is a subject of great importance both to the practical engineer and to the speculative philosopher. It is therefore our duty to correct, in this Supplement, the mistakes into which we fell when treating of that subject in the *Encyclopædia.* What we have there taught of friction (see MECHANICS Sect. II. § 8.) is taken from Ferguson; but it has been shewn by Mr Vince, that the experiments from which his conclusions were drawn were not properly instituted. That eminent mathematician and philosopher therefore entered upon the investigation of the subject anew, and endeavoured, by a set of experiments, to determine the following questions:

1. Whether friction be a uniformly retarding force?
2. The quantity of friction?
3. Whether the friction varies in proportion to the pressure or weight?
4. Whether the friction be the same on whichever of its surfaces a body moves?

1. With respect to the first of these questions, the author truly observes, that if friction be a uniform force, the difference between it and the given force of the moving power employed to overcome it must also be uniform; and that therefore the moving power, if it be a body descending by its own weight, must descend with a uniformly accelerated velocity, just as when there was no friction. The spaces described from the beginning of the motion will indeed be diminished in any given time on account of the friction; but still they must be to each other as the squares of the times employed. See DYNAMICS in this *Supplement.*

2. A plane was therefore adjusted parallel to the horizon, at the extremity of which was placed a pulley, which could be elevated or depressed in order to render the string which connected the body and the moving force parallel to the plane. A scale accurately divided was placed by the side of the pulley perpendicular to the horizon, by the side of which the moving force descended; upon the scale was placed a moveable stage, which could be adjusted to the space through which the moving force descended in any given time; which time was measured by a well-regulated pendulum clock vibrating seconds. Every thing being thus prepared, the following experiments were made to ascertain the law of friction.

3. *Exp.* 1. A body was placed upon the horizontal plane, and a moving force applied, which, from repeated trials, was found to descend $52\frac{1}{2}$ inches in 4″; for by the beat of the clock, and the sound of the moving force when it arrived at the stage, the space could be very accurately adjusted to the time: The stage was then removed to that point to which the moving force would descend in 3″, upon supposition, that the spaces described by the moving power were as the squares of the times; and the space was found to agree very accurately with the time: the stage was then removed to that point to which the moving force ought to descend 2″ upon the same supposition, and the descent was found to agree exactly with the time: lastly, the stage was adjusted to that point to which the moving force ought to descend in 1″, upon the same supposition, and the space was observed to agree with the time. Now, in order to find whether a difference in the time of descent could be observed by removing the stage a little above and below the positions which corresponded to the above times the experiment was tried, and the descent was always found too soon in the former, and too late in the latter case; by which the author was assured that the spaces first mentioned corresponded exactly to the times. And, for the greater certainty, each descent was repeated eight or ten times; and every caution used in this experiment was also made use of in all the following.

Exp. 2. A second body was laid upon the horizontal plane, and a moving force applied which descended $41\frac{3}{5}$ inches in 3″; the stage was then adjusted to the space corresponding to 2″, upon supposition that the spaces descended through were as the squares of the times, and it was found to agree accurately with the time; the stage was then adjusted to the space corresponding to 1″, upon the same supposition, and it was found to agree with the time.

Exp. 3. A third body was laid upon the horizontal plane, and a moving force applied, which descended $59\frac{5}{8}$ inches in 4″; the stage was then adjusted to the space corresponding to 3″, upon supposition that the spaces descended through were as the squares of the times, and it was found to agree with the time; the stage was then adjusted to the space corresponding to 2″, upon the same supposition, and it was found to agree with the time; the stage was then adjusted to the space corresponding to 1″, and was found to agree with the time.

Exp. 4. A fourth body was then taken and laid upon the horizontal plane, and a moving force applied, which descended 55 inches in 4″; the stage was then adjusted to the space through which it ought to descend in 3″, upon supposition that the spaces descended through were as the squares of the times, and it was found to agree with the time; the stage was then adjusted to the space corresponding to 2″, upon the same supposition, and was found to agree with the time; lastly, the stage was adjusted to the space corresponding to 1″, and it was found to agree exactly with the time.

Besides these experiments, a great number of others were made with hard bodies, or those whose parts so firmly cohered as not to be moved *inter se* by the friction; and, in each experiment, bodies of very different degrees of friction were chosen, and the results all agreed with those related above; we may therefore conclude, that the *friction of hard bodies in motion is a uniformly retarding force.*

But to determine whether the same was true for bodies when covered with cloth, woollen, &c. experiments were made in order to ascertain it; when it was found, in all cases, that the retarding force increased with the velocity; but, upon covering bodies with paper, the consequences were found to agree with those related above.

4. Having proved that the retarding force of all hard bodies arising from friction is uniform, the quantity of friction, considered as equivalent to a weight without inertia drawing the body on the horizontal plane backwards, or acting contrary to the moving force, may be immediately deduced from the foregoing experiments. For let M = the moving force expressed by its weight; F = the friction; W = the weight of the body upon the horizontal plane; S = the space through which the moving force descended in the time *t* expressed in seconds; $r = 16\frac{1}{12}$ feet; then the whole accelerative

force (the force of gravity being unity) will be $\frac{M - F}{M + W}$; hence, by the laws of uniformly accelerated motions, $\frac{M - F}{M + W} \times rt^2 = S$, consequently $F = M - \frac{\overline{M \times W} \times S}{rt^2}$ To exemplify this, let us take the case of the last experiment, where $M = 7$, $W = 25\frac{3}{4}$, $S = 4\frac{7}{12}$ feet, $t = 4''$; hence $F = 7 - \frac{32\frac{3}{4} \times 4\frac{7}{12}}{16\frac{1}{12} \times 16} = 6.417$; consequently the friction was to the weight of the rubbing body as 6.4167 to 25.75. And the great accuracy of determining the friction by this method is manifest from hence, that if an error of 1 inch had been made in the descent (and experiments carefully made may always determine the space to a much greater exactness), it would not have affected the conclusion $\frac{1}{600}$dth part of the whole.

5. We come in the next place to determine, whether friction, *cæteris paribus*, varies in proportion to the weight or pressure. Now if the whole quantity of the friction of a body, measured by a weight without inertia equivalent to the friction drawing the body backwards, increases in proportion to its weight, it is manifest, that the retardation of the velocity of the body arising from the friction will not be altered; for the retardation varies as $\frac{\text{Quantity of friction}}{\text{Quantity of matter}}$; hence, if a body be put in motion upon the horizontal plane by any moving force, if both the weight of the body and the moving force be increased in the same ratio, the acceleration arising from that moving force will remain the same, because the accelerative force varies as the moving force divided by the whole quantity of matter, and both are increased in the same ratio; and if the quantity of friction increases also as the weight, then the retardation arising from the friction will, from what has been said, remain the same, and therefore the whole acceleration of the body will not be altered; consequently the body ought, upon this supposition, still to describe the same space in the same time. Hence, by observing the spaces described in the same time, when both the body and the moving force are increased in the same ratio, we may determine whether the friction increases in proportion to the weight. The following experiments were therefore made in order to ascertain this matter:

Exp. 1. A body weighing 10 oz. by a moving force of 4 oz. described in 2′ a space of 51 inches; by loading the body with 10 oz. and the moving force with 4 oz. it described 56 inches in 2″; and by loading the body again with 10 oz. and the moving force with 4 oz. it described 63 inches in 2″.

Exp. 2. A body, whose weight was 16 oz. by a moving force of 5 oz. described a space of 49 inches in 3″; and by loading the body with 64 oz. and the moving force with 20 oz. the space described in the same time was 64 inches.

Exp, 3. A body weighing 6 oz. by a moving force of $2\frac{1}{2}$ oz. described 28 inches in 2″; and by loading the body with 24 oz. and the moving force with 10 oz. the space described in the same time was 54 inches.

Exp. 4. A body weighing 8 oz. by a moving force of 4 oz. described $33\frac{1}{2}$ inches in 2″; and by loading the body with 8 oz. and the moving force with 4 oz. the space described in the same time was 47 inches.

Exp. 5. A body whose weight was 9 oz. by a moving force of $4\frac{1}{2}$ oz. described 48 inches in 2′; and by loading the body with 9 oz. and the moving force with $4\frac{1}{2}$ oz. the space described in the same time was 60 inches.

Exp. 6. A body weighing 10 oz. by a moving force of 3 oz. described 20 inches in 2″; by loading the body with 10 oz. and the moving force with 3 oz. the space described in the same time was 31 inches; and by loading the body again with 30 oz. and the moving force with 9 oz. the space described was 34 inches in 2″.

From these experiments, and many others which it is not necessary here to relate, it appears, that the space described is always increased by increasing the weight of the body and the accelerative force in the same ratio; and as the acceleration arising from the moving force continued the same, it is manifest, that the retardation arising from the friction must have been diminished, for the whole accelerative force must have been increased on account of the increase of the space described in the same time; and hence (as the retardation from friction varies as $\frac{\text{Quantity of friction}}{\text{Quantity of matter}}$) *the quantity of friction increases in a less ratio than the quantity of matter or weight of the body.*

6. We come now to the last thing which it was proposed to determine, that is, whether the friction varies by varying the surface on which the body moves. Let us call two of the surfaces A and *a*, the former being the greater, and the latter the less. Now the weight on every given part of *a* is as much greater than the weight on an equal part of A, as A is greater than *a*; if therefore the friction was in proportion to the weight, *cæteris paribus*, it is manifest, that the friction on *a* would be equal to the friction on A, the whole friction being, upon such a supposition, as the weight on any given part of each surface multiplied into the number of such parts or into the whole area, which products, from the proportion above, are equal. But from the last experiments it has been proved, that the friction on any given surface increases in a less ratio than the weight; consequently the friction on any given part of *a* has a less ratio to the friction on an equal part of A than A has to *a*, and hence the friction on *a* is less than the friction on A, that is, the smallest surface has always the least friction.

As this conclusion is contrary to the generally received opinion, Mr Vince thought it proper to confirm it by a set of experiments made with different bodies of exactly the same degree of roughness on their two surfaces.

Exp. 1. A body was taken whose flat surface was to its edge as 22 : 9, and with the same moving force the body described on its flat side $33\frac{1}{2}$ inches in 2″, and on its edge 47 inches in the same time.

Exp. 2. A second body was taken whose flat surface was to its edge as 32 : 3, and with the same moving force it described on its flat side 32 inches in 2″, and on its edge it described $37\frac{1}{2}$ inches in the same time.

Exp. 3. He took another body and covered one of its surfaces, whose length was 9 inches, with a fine rough paper, and by applying a moving force, it described 25 inches in 2″; he then took off some paper from the

Friction. the middle, leaving only $\frac{3}{8}$ of an inch at the two ends, and with the same moving force it described 40 inches in the same time.

Exp. 4. Another body was taken which had one of its surfaces, whose length was 9 inches, covered with a fine rough paper, and by applying a moving force it described 42 inches in 2″; some of the paper was then taken off from the middle, leaving only $1\frac{1}{8}$ inches at the two ends, and with the same moving force it described 54 inches in 2″; he then took off more paper, leaving only $\frac{1}{7}$ of an inch at the two ends, and the body then described, by the same moving force, 60 inches in the same time.

In the two last experiments the paper which was taken off the surface was laid on the body, that its weight might not be altered.

Exp. 5. A body was taken whose flat surface was to its edge as 30 : 17; the *flat* side was laid upon the horizontal plane, a moving force was applied, and the stage was fixed in order to stop the moving force, in consequence of which the body would then go on with the velocity acquired until the friction had destroyed all its motion; when it appeared from a mean of 12 trials that the body moved, after its acceleration ceased, $5\frac{2}{5}$ inches before it stopped. The *edge* was then applied, and the moving force descended through the same space; and it was found, from a mean of the same number of trials, that the space described was $7\frac{1}{7}$ inches before the body lost all its motion, after it ceased to be accelerated.

Exp. 6. Another body was then taken whose flat surface was to its edge as 60 : 19, and, by proceeding as before, on the flat surface it described, at a mean of 12 trials $5\frac{1}{8}$ inches, and on the edge $6\frac{1}{14}$ inches, before it stopped, after the acceleration ceased.

Exp. 7. Another body was taken whose flat surface was to its edge as 26 : 3, and the spaces described on these two surfaces, after the acceleration ended, were, at a mean of ten trials, $4\frac{1}{7}$ and $7\frac{7}{10}$ inches respectively.

From all these different experiments it appears, that the smallest surface had always the least friction, which agrees with the consequence deduced from the consideration that the friction does not increase in so great a ratio as the weight; we may therefore conclude, that *the friction of a body does not continue the same when it has different surfaces applied to the plane on which it moves, but that the smallest surface will have the least friction.*

To the experiments instituted by Mr Ferguson and others, from which conclusions have been drawn so different from these, our author makes the following objections: It was their object to find what moving force would *just* put a body at rest in motion; and having, as they thought, found it, they thence concluded, that the accelerative force was then equal to the friction. But it is manifest, as Mr Vince observes, that any force which will put a body in motion must be *greater* than the force which opposes its motion, otherwise it could not overcome it; and hence, if there were no other objection than this, it is evident, that the friction could not be very accurately obtained: but there is another objection which totally destroys the experiment so far as it tends to shew the quantity of friction, which is the strong cohesion of the body to the plane when it lies at rest; and this is confirmed by the following experiments. 1*st*, A body of $12\frac{1}{4}$ oz. was laid upon an horizontal plane, and then loaded with a weight of 8lb. and such a moving force was applied as would, when the body was just *put* in motion, continue that motion without any acceleration; in which case the friction must be just equal to the accelerative force. The body was then stopped, when it appeared, that the same moving force which had *kept* the body in motion before, would not *put* it in motion, and it was found necessary to take off $4\frac{1}{2}$ oz. from the body before the same moving force *would* put it in motion; it appears therefore, that this body, when laid upon the plane, at rest, acquired a very strong cohesion to it. 2*dly*, A body whose weight was 16 oz. was laid at rest upon the horizontal plane, and it was found that a moving force of 6 oz. would just *put* it in motion; but that a moving force of 4 oz. *would*, when it was just put in motion, continue that motion without any acceleration, and therefore the accelerative force must *then* have been equal to the friction, and not when the moving force of 6 oz. was applied.

From these experiments therefore it appears, how very considerable the cohesion was in proportion to the friction when the body was in motion; it being, in the latter case, almost $\frac{1}{3}$d, and in the former it was found to be very nearly equal to the whole friction. All the conclusions therefore deduced from the experiments, which have been instituted to determine the friction from the force necessary to *put* a body in motion, have manifestly been totally false; as such experiments only shew the resistance which arises from the cohesion and friction conjointly.

Our author concludes this part of his subject with the following remark upon n° 5: "It appears from all the experiments (says he) which I have made, that the proportion of the increase of the friction to the increase of the weight was different in all the different bodies which were made use of; no general rule therefore can be established to determine this for *all* bodies, and the experiments which I have hitherto made have not been sufficient to determine it for the *same* body."

He then proceeds to establish a theory upon the principles which he has deduced from his experiments. That theory is comprehended in five propositions, of which the object of the first is "to find the time of descent, and the number of revolutions made by a cylinder rolling down an inclined plane in consequence of its friction.

II. "To determine the space through which a body, projected on an horizontal plane with a given velocity, will move before it stops, or before its motion becomes uniform.

III. "To find the centre of friction.

IV. "To determine, from the given velocity with which a body begins to revolve about the centre of its base, the number of revolutions which that body will make before all its motion be destroyed.

V. "To find the nature of the curve described by any point of a body affected by friction when it descends down any inclined plane."

To give the solutions of these problems, with the corollaries deduced from them, would swell this article to very little purpose; for they would be unintelligible to the mere mechanic, and the mathematician will either solve them for himself, or have recourse to the original

 memoir,

memoir, where he will find solutions at once elegant and perspicuous.

FRIEDBURG, a Moravian settlement in Wachovia, or Surry co. N. Carolina.—*Morse.*

FRIEDENSHUETTEN, a Moravian settlement, whose name signifies *Tents of Peace*, situated on Susquehanna river, in Pennsylvania, about 24 miles below Tioga point; established by the United Brethren in 1765. It then consisted of 13 Indian huts, and upwards of 40 houses, built after the European manner, with a neat chapel. Next to the houses the ground was laid out in gardens; and between the settlement and the river about 250 acres were divided into regular plantations of Indian corn.—*ib.*

FRIEDENSTADT, or *Town of Peace*, a Moravian settlement which was established between Great Beaver and Yellow creeks; about 40 miles N. W. of Pittsburg. It was abandoned in 1773.—*ib.*

FRIGORIFIC MIXTURES, are those which experience has taught philosophers to employ for the purpose of producing artificial cold. Some of these mixtures are enumerated under the title COLD (*Encycl*), and a much more accurate list of them is given, together with the principle upon which they produce their effect, in the article CHEMISTRY, n° 282. (*Suppl.*) There is one mixture, however, not mentioned in that list, which was employed by Seguin, and seems, on many accounts, to be the most eligible that has yet been proposed. Considering the muriats (see CHEMISTRY-*Index-Suppl.*) as a class of salts best suited for the purpose, he gave the decided preference to muriat of lime in chrystals; and his method was to mix the crystals, previously pulverised, with an equal weight of uncompressed snow.

By means of this mixture Mr W. H. Pepys junior, of the London Philosophical Society, with the assistance of some friends, froze, on the 8th of February 1799, 56 lbs. averdupoise of mercury into a solid mass. The mercury was put into a strong bladder and well secured at the mouth, the temperature of the laboratory at the time being + 33°. A mixture consisting of muriat of lime 2 lb. at + 33°, and the same weight of snow at + 32° gave — 42° (A). The mercury was put as gently as possible into this mixture (to prevent a rupture of the bladder), by means of a cloth held at the four corners. When the cold mixture had robbed the mercury of so much of its heat as to have its own temperature thereby raised from — 42° to + 5, another mixture, the same in every respect as the last, was made, which gave, on trial with the thermometer, — 43°. The mercury was now received into the cloth, and put gently into this new mixture, where it was left to be cooled still lower than before.

In the mean time five pounds of muriat of lime, in a large pail made of tinned iron, and japanned inside and outside, was placed in a cooling mixture in an earthenware pan. The mixture in the pan, which consisted of 4lb. of muriat of lime and a like quantity of snow, of the same temperature as the former, in one hour reduced the 5 lb. of muriat in the pail to — 15°. The mixture was then emptied out of the earthen pan, and four large corks, at proper distances, placed on its bottom, to serve as rests for the japanned pail which was now put into the pan. The corks answered the purpose of insulating the inner vessel, while the exterior one kept off the surrounding atmosphere, and preserved the air between the two at a low temperature.

To the 5 lb. of muriat of lime which had been cooled, as already noticed, to — 15°, and which still remained in the metallic vessel, was now added snow, uncompressed and free from moisture, at the usual temperature of + 32°. In less than three minutes the mixture gave a temperature of — 62° : a degree of cold which perhaps was never before produced in this country, being 94° below the freezing point of water.

The mercury, which by immersion in the second cooling mixture to which it was exposed, was, by this time reduced to — 30°, was now, by the means employed before, cautiously put into the last made mixture of the temperature of — 62°. A hoop, with net-work fastened to its upper edge, and of such a breadth in the rim that the net work, when loaded with the bladder of mercury could not reach its lower edge, was at the bottom of the mixture, to prevent the bladder from coming in contact with the vessel; by which means the mercury was suspended in the middle of the mixture. As soon as the bladder was safely deposited on the net-work, the vessels were carefully covered over with a cloth, to impede the passage of heat from the surrounding atmosphere into the freezing materials. The condensation of moisture from the atmosphere by the agency of so low a temperature was greater than could have been expected: It floated like steam over the vessels, and, but for the interposed covering, would have given the mixture more temperature than was desirable.

After one hour and forty minutes they found, by means of a searcher introduced for the purpose, that the mercury was solid and fixed. The temperature of the mixture at this time was — 46, that is 16° higher than when the mercury was put into it.

Our young philosophers having neglected to sling the hoop and net-work in such a manner as might have enabled them to lift it out of the mixture at once, with the bladder and its contents, were obliged to turn out the whole contents of the pail into a large evaporating capsule made of iron. This was not effected without the mercury striking against its bottom and being fractured, though it received a considerable increase of temperature from the capsule. The fracture was similar to that of zinc, but with parts more cubical. The larger pieces were kept for some minutes before fusion took place, while others were twisted and bent into various forms, to the no small gratification and surprise of those who had never witnessed or expected to see such an effect produced on so fusible a metal.

In experiments of the kind here described, all the exterior vessels should be of earthen-ware or wood, which being bad conductors of heat, prevent the ingredients from receiving heat from the atmosphere and surrounding objects with the same facility that they would through metals; and, for a similar reason, the interior vessels are best of metal, that they may allow the

(A) The thermometer made use of in this experiment was filled with tinged alcohol, and accurately divided according to Fahrenheit's scale.

the heat to paſs more readily from the ſubſtance to be cooled into the frigorific mixture employed for that purpoſe.

Muriat of lime is certainly the moſt powerful, and at the ſame time the moſt economical ſubſtance that can be employed for producing artificial cold; for its firſt coſt is a mere trifle, being a reſiduum from many chemical proceſſes, as the diſtillation of pure ammonia, &c. and often thrown away: beſides, it may be repeatedly uſed for ſimilar experiments, nothing being neceſſary for this purpoſe but filtration and evaporation to bring it to its firſt ſtate. The evaporation ſhould be carried on till the ſolution becomes as thick as a ſtrong ſyrup, and upon cooling the whole will be cryſtalliſed: it muſt then be powdered, put up in dry bottles, well corked, and covered with bladder or cement to prevent liquefaction; which otherwiſe would ſoon take place, owing to the great affinity the muriat has for moiſture.

The powerful effects produced by the frigorific mixture of muriat of lime and ſnow, preſent a wide field for experiments to determine the poſſibility of fixing ſome of the gaſes by intenſe cold. And we are happy to be informed by Mr Pepys, that, as ſoon as an opportunity offers, he and his friends mean to make ſome experiments with that view, and to communicate the reſult of them to the editor of the valuable miſcellany* from which we have taken this account of his experiment on mercury.

* *The Philoſophical Magazine.*

FRIO, a ſmall iſland on the coaſt of the Brazils, ſituated in 32° 2′ ſouth lat. and 41° 31′ 45″ weſt lon. The land of Frio is high, with a hollow in the middle, which gives it, at a diſtance, the reſemblance of two ſeparate iſlands. The paſſage between the iſland and the continent is about a mile broad, and ſeemed to Sir Eraſmus Gower to be clear from ſhoals.

FRONTINAC, Fort, a fortreſs in Canada, ſituated at the head of a fine bay or harbor, on the N. W. ſide of the outlet of Lake Ontario, where all ſorts of veſſels may ride in ſafety. It is a league from the mouth of the lake, and a ſhort diſtance S. of Kingſton, and about 300 miles from Quebec. The winter about this place is much ſhorter than at Quebec; and the ſoil is ſo well cultivated, as to produce all ſorts of European and Indian corn, and fruits. Here is one of the moſt charming proſpects in the world, during ſpring and ſummer. The St Lawrence and the mouth of Lake Ontario, contain a number of beautiful and fertile iſlands of different magnitudes, and well wooded, and the bay often preſents to the view veſſels at anchor, and others paſſing to and from the lake. But the misfortune is, that the advantageous communication between this lake, Montreal and Quebec, is ſomewhat difficult and dangerous, on account of the river being full of rocks and water falls. This, together with the ambuſcades of the Iroquois Indians, induced the French to abandon and deſtroy the ſtrong works they had erected here. This happened in 1689. After this they retook and repaired the place. At length the Britiſh, under col. Bradſtreet, took it in 1759, to whom it was confirmed at the peace in 1763.

A river has lately been ſurveyed by the deputy ſurveyor general of Canada, from its entrance into the lake at Kenty, near Cadaraqui, to its ſource in lake St Clie; from which there is an eaſy and ſhort portage acroſs N. W. to the N. E. angle of Lake Huron, and another that is neither long nor difficult, to the ſouthward, to the old ſettlement of Toronto. This is a ſhort route from Fort Frontenac to Michillimackinack. —*Morſe.*

FROST, as is well known in Scotland, is particularly deſtructive to the bloſſom of fruit trees; and the following method of ſecuring ſuch trees from being damaged by early froſts may be acceptable to many of our readers. A rope is to be interwoven among the branches of the tree, and one end of it brought down ſo as to be immerſed in a bucket of water. The rope, it is ſaid, will act as a conductor, and convey the effects of the froſt from the tree to the water. This idea is not new, for the following paſſage may be found in Colerus: "If you dig a trench around the root of a tree, and fill it with water, or keep the roots moiſt till it has bloomed, it will not be injured by the froſt. Or, in ſpring, ſuſpend a veſſel filled with water from the tree. If you wiſh to preſerve the bloom from being hurt by the froſt, place a veſſel of water below it, and the froſt will fall into it." *Philoſophical Magazine*, n° 11.

FROWSAC *Channel*, or the Gut of Canſo, a ſtrait between Nova-Scotia and Cape Breton Iſland, 5 French leagues long, and one broad.—*Morſe.*

FRYDUFFRIN, a townſhip in Cheſter co. Pennſylvania.—*ib.*

FRYING PAN, a dangerous ſhoal ſo called from its form. It lies at the entrance of Cape Fear river, in North Carolina; the S. part of it is in N. lat. 33. 32. 6 miles from Cape Fear pitch, and 24 S. E. by S. from the light-houſe on Bald Head.

FRYSBURGH, or *Fryburg*, a townſhip pleaſantly ſituated in York co. in the diſtrict of Maine, in a bow formed by the N. branch of Great Oſſipee river. It was incorporated in 1777, has a flouriſhing academy, and contains 447 inhabitants. This is the ancient Indian village Peckwalket, through which the upper part of Saco meanders; 60 miles from the ſea, and 120 N. by E. of Boſton. N. lat. 44. 2. W. long. 70. 47. 30.—*ib.*

FUCA, Straits of Juan de, lie on the N. W. coaſt of N. America. The entrance lies between Cape Flattery on the S. ſide, in N. lat. 48. 25. W. long. 124. 52. to the oppoſite coaſt of the Quadras iſles, in N. lat. 48. 53. 30. It communicates with Pintard's ſound, and thus forms Quadras iſles; in the S. eaſtern coaſt of which lies Nootka ſound. The Spaniards, jealous of their right to the American coaſt, eſtabliſhed a ſettlement at this place.—*ib.*

FUEL, whatever is proper to burn, or make a fire, either for warming a room or dreſſing victuals. The fuel moſt generally uſed in Great Britain is pit coal, which is a very expenſive article; and that expence is greatly increaſed by the waſte of coal occaſioned by the injudicious manner in which fires in open chimneys are commonly managed. The enormous waſte of fuel in London, for inſtance, may be eſtimated by the vaſt dark cloud which continually hangs over that great metropolis, and frequently overſhadows the whole country far and wide; for this denſe cloud is certainly compoſed almoſt entirely of unconſumed coal, which has eſcaped by the chimneys, and continues to ſail about in the air, till, having loſt the heat which gave it volatility, it falls in a dry ſhower of extremely fine black duſt to the ground, Fuel.

ground, obscuring the atmosphere in its descent, and frequently changing the brightest day into more than Egyptian darkness.

"I never (says Count Rumford) view from a distance, as I come into town, this black cloud which hangs over London, without wishing to be able to compute the immense number of chaldrons of coals of which it is composed; for could this be ascertained, I am persuaded so striking a fact would awaken the curiosity, and excite the astonishment of all ranks of the inhabitants; and perhaps turn their minds to an object of economy to which they have hitherto paid little attention."

The object to which the benevolent author more particularly wishes to direct the public attention, is the lighting of a coal fire, in which more wood should be employed than is commonly used, and fewer coals; and as soon as the fire burns bright, and the coals are well lighted, and not before, more coals should be added to increase the fire to its proper size.

Kindling balls, composed of equal parts of coal,—charcoal,—and clay, the two former reduced to a fine powder, well mixed and kneaded together, with the clay moistened with water, and then formed into balls of the size of hens eggs, and thoroughly dried, might be used with great advantage instead of wood for kindling fires. These kindling balls may be made so inflammable as to take fire in an instant and with the smallest spark, by dipping them in a strong solution of nitre and then drying them again: and they would neither be expensive nor liable to be spoiled by long keeping. Perhaps a quantity of pure charcoal, reduced to a very fine powder, and mixed with the solution of nitre in which they are dipped, would render them still more inflammable.

The Count thinks that the fires which are made in the open chimneys of elegant apartments might be greatly improved by preparing the fuel; for nothing (says he) was ever more dirty, inelegant, and disgusting than a common coal fire.

Fire balls, of the size of goose eggs, composed of coal and charcoal in powder, mixed up with a due proportion of wet clay, and well dried, would make a much more cleanly, and in all respects a pleasanter fire than can be made with crude coals; and, he believes, would not be more expensive fuel. In Flanders, and in several parts of Germany, and particularly in the duchies of Juliers and Bergen, where coals are used as fuel, the coals are always prepared before they are used, by pounding them to a powder, and mixing them up with an equal weight of clay, and a sufficient quantity of water to form the whole into a mass, which is kneaded together and formed into cakes; which cakes are afterwards well dried, and kept in a dry place for use. And it has been found, by long experience, that the expence attending this preparation is amply repaid by the improvement of the fuel. The coals, thus mixed with clay, not only burn longer, but give much more heat than when they are burnt in their crude state.

It will doubtless appear extraordinary to those who have not considered the subject with some attention, that the quantity of heat produced in the combustion of any given quantity of coals should be increased by mixing the coals with clay, which is certainly an incombustible body; but the phenomenon may be explained in a satisfactory manner.

The heat generated in the combustion of any small particle of coal existing under two distinct forms, namely, in that which is combined with the flame and smoke which rise from the fire, and which, if means are not found to stop it, goes off immediately by the chimney and is lost, and the radiant heat which is sent off from the fire in all directions in right lines:—It is therefore reasonable to conclude, that the particles of clay, which are surrounded on all sides by the flame, arrest a part at least of the combined heat, and prevent its escape; and this combined heat, so arrested, heating the clay red hot, is retained in it, and being changed by this operation to radiant heat, is afterwards emitted, and may be directed and employed to useful purposes. In the composition of fire balls, the Count thinks it probable that a certain proportion of chaff, of straw cut very fine, or even of saw dust, might be employed with great advantage.

Fulling.

FULLING OF WOOLLEN CLOTHS (see the method of performing the operation under the article FULLING, *Encycl.*) depends, like FELTING, so entirely upon the structure of wool and hair, that the following observations, which are not unimportant, will be intelligible to every reader who has perused that article in this *Supplement*.

The asperities with which the surface of wool is every where surrounded, and the disposition which it has to assume a progressive motion towards the root, render the spinning of wool, and making it into cloth, difficult operations. In order to spin wool, and afterwards to weave it, we are obliged to cover its fibres with a coating of oil, which, filling the cavities, renders the asperities less sensible; in the same way as oil, when rubbed over the surface of a very fine file, renders it still less rough. When the piece of cloth is finished, it must be cleansed from this oil; which, besides giving it a disagreeable smell, would cause it to soil whatever it came in contact with, and would prevent its taking the colour which is intended to be given to it by the dyer. To deprive it of the oil, it is carried to the fulling-mill, where it is beat with hammers in a trough full of water, in which some clay has been mixed; the clay combines with the oil, which it separates from the cloth, and both together are washed away by the fresh water which is brought to it by the machine; thus, after a certain time, the oil is entirely washed out of the cloth.

But the scouring of the cloth is not the only object in fulling it; the alternate pressure given by the mallets to the piece of cloth, occasions, especially when the scouring is pretty far advanced, an effect analogous to that which is produced upon hats by the hands of the hatter; the fibres of wool which compose one of the threads, whether of the warp or the woof, assume a progressive movement, introduce themselves among those of the threads nearest to them, then into those which follow; and thus, by degrees, all the threads, both of the warp and the woof become felted together. The cloth, after having, by the above means, become shortened in all its dimensions, partakes both of the nature of cloth and of that of felt; it may be cut without being subject to ravel, and, on that account, we are not obliged to hem the edges of the pieces of which clothes are made. Lastly, As the threads of the warp and those of the woof are no longer so distinct and separated from each other, the cloth, which has acquired a greater degree of thickness, forms a warmer clothing. Knit worsted

also

also is, by fulling, rendered less apt to run, in case a stitch should drop in it.

FULMINATING GOLD. } See CHEMISTRY *Suppl.*
FULMINATING Silver. } nos 849 and 850.

Mr Berthollett, the inventor of fulminating silver, having contented himself with a general and concise description of this subject, many practical chemists have failed in their attempts to prepare it; and others, forming their opinions from the specimens which they had made, have been exposed to great danger: as will appear from the following relation:

An ounce of fine silver was dissolved in the course of eight hours in an ounce of pure nitrous acid, of the London Pharmacopœia, diluted previously with three ounces of distilled water in a glass matrass. The solution being poured off, the residuary black powder and the matrass were washed with seven or eight ounces of warm distilled water, and this was added to the solution. The black powder, being gold, was rejected; some gold being thus separable from any silver of commerce.

To the foregoing diluted solution, pure lime-water prepared with distilled water was added gradually; for the solution ought not to be poured into the lime water. When about thirty pints of lime-water had been expended, and the precipitate had subsided, more lime-water was added, by successive pints, as long as it caused any precipitation. For it was deemed fitter that the precipitation should not be perfected, than that an excess of lime-water should be used; the earthy pellicle of the excessive lime-water being apt to mix with the precipitate. The clear liquor being poured away, the precipitate was poured off, and washed into a filter.

When the saline liquor had drained from it, two ounces of distilled water were poured on the magma; and when this water had passed, fresh portions were successively added and passed, until the whole quantity of water thus expended in washing away the nitrous calcareous salt amounted to a quart.

The filter being then unfolded, to let the magma of oxyd of silver spread on the flattened paper, it was placed on a chalk-stone to accelerate the exsiccation, and was gradually dried in the open air; a cap of paper being placed loosely over it to exclude the dust.

When the weather served, the cap was removed, to expose the oxyd to the rays of the sun; although this was not deemed neccessary; and exsiccation was promoted by cutting the oxyd into thin slices. When perfectly dry it weighed 1 oz. 4 dwts. and about one-fifth of it was considered as oxygen.

When aqua ammoniæ puræ of any pharmacopœia is used with this oxyd, either in the small quantity which blackens it completely, or in a greater quantity, the black matter which subsides, and which has been represented by systematic writers as the fulminating compound, has no such property, any farther than may be owing to the matter deposited from the alkaline solution during the exsiccation.

The alkaline liquor containing the fulminating silver ought to be poured off from the insoluble powder, and exposed in a shallow vessel to the air. In consequence of the exhalation, black shining crystals form on the surface only, and soon join to form a pellicle. As this pellicle adheres a little to the sides of the vessel, or maintains its figure, the liquor may be poured off by a gentle inclination of the vessel.

This liquor will yield another pellicle in the same way; but the third or fourth pellicle will be paler than the former, and weaker in the explosion. The first pellicles, when slowly dried, explode by the touch of a feather, or by their being heated to about 96°.

The quantity of water in the ordinary aqua ammoniæ puræ renders it less active in the solution of the oxyd, and is an impediment to the speedy formation and separation of the fulminating silver; and an experimenter who has often used twenty grains of the oxyd to produce successive pellicles of fulminating silver, which may be separately exploded with safety, and who has perceived that the pellicles never explode whilst wet, if they be not heated, would, in all probability, resolve on the following improvement, and expose himself to the unforeseen danger of it.

Distilled water was impregnated with as much pure ammoniac, as it could easily retain under the ordinary temperature of the air. A quantity of this strong ammoniacal liquor, equal in bulk to a quarter of an ounce of water, was placed in a small bottle, and 24 grains of the oxyd of silver, ground to fine powder, were added. The bottle, being almost filled, was corked, to prevent the formation of that film which usually appeared in consequence of the exhalation of the ammoniac in other experiments.

During the solution of the oxyd, bubbles of the gaseous kind arose from it, and the solution acquired a blue colour. As no film appeared, the bottle was agitated three or four times in the course of as many hours, in order to promote the solution of a small quantity of blackened oxyd which remained at the bottom. The experimenter considering this as an ample provision for twenty different charges, to be exploded in different circumstances, in the presence of the society, intended to pour off the solution into as many small vessels, and to weigh the residuary black powder, after allowing two hours more for the solution.

On the sixth hour he took his usual precaution of wearing spectacles; and observing that a small quantity of black powder still remained undissolved, and that no film was yet formed at the surface, he took the bottle by the neck to shake it, knowing that it might explode by the heat of his hand, if he were to grasp it, and that the explosion in this circumstance might wound him dangerously.

In the instant of shaking, it exploded with a report that stunned him. The bottle was blown into fragments so small as to appear like glass coarsely powdered. The hand which held it was impressed as by the blow of a great hammer, and lost the sense of feeling for some seconds; and about 52 small grains of glass were lodged, many of them deeply, in the skin of the palm and fingers. The liquor stained his whole dress, and every part of the skin that it touched. Thus it appeared that fulminating silver may be made which will explode even when cold and wet, by the mere disturbance of the arrangement of its parts, in the aqueous fluid.

In subsequent experiments, privately and carefully conducted, it seemed that the property of exploding in the cold liquor, by mere commotion, depended on the unusual quantity or proximity of the explosive molecules in a given bulk of the liquor. And the flat bottoms, as well as the sides, of the thick vessels of glass or pot-

ters-

ters-ware, whether they ſtood on boards or iron plates, were always beaten to ſmall fragments.

This afforded a curious inſtance of the poſſible equilibrium between the powers tending to retain the caloric and thoſe which effect the expulſion of it; and experiments and conſiderations of this kind ſeemed to promiſe a true ſolution of the phenomena of Rupert's drops.

FUNCTION, a term uſed in analytics for an algebraical expreſſion any how compounded of a certain letter or quantity with other quantities or numbers; and the expreſſion is ſaid to be a function of that letter or quantity. Thus $a - 4x$, or $ax + 3x^2$, or $2x - a\sqrt{a^2 - x^2}$, or x^c, or c^x, is each of them a function of the quantity x.

FUNDY, a large bay in N. America, which opens between the iſlands in Penobſcot bay, in Lincoln co. Maine, and Cape Sable, the S. weſtern point of Nova-Scotia. It extends about 200 miles in a N. E. direction; and with Verte bay, which puſhes into the land in a S. W. direction from the ſtraits of Northumberland, forms a very narrow iſthmus, which unites Nova-Scotia to the continent; and where the diviſion line runs between that province and New-Brunſwick. From its mouth up to Paſſamaquoddy bay, on its N. W. ſide, ſituated between the province of New-Brunſwick and the diſtrict of Maine, are a number of bays and iſlands on both ſides, and thus far it contracts its breadth gradually. It is 12 leagues acroſs from St John's, in New-Brunſwick, to the Gut of Annapolis, in Nov-Scotia; where the tides are rapid, and riſe 30 feet. Above this it preſerves nearly an equal breadth, until its waters are formed into two arms, by a peninſula, the weſtern point of which is called Cape Chignecto. At the head of the N. eaſtern arm, called Chignecto channel, which, with bay Verte forms the iſthmus, the tides riſe 60 feet. In the Baſin of Minas, which is the E. arm or branch of this bay, the tides riſe 40 feet. Theſe tides are ſo rapid as to overtake animals feeding on the ſhore.—*Morse.*

FURD-Y-HUCKEECUT, in Bengal, ſignifies a paper of deſcription.

Furd-y-Sowal, paper of requeſt.

FUST, in architecture, the ſhaft of a column, or the part comprehended between the baſe and the capital, called alſo the naked.

G.

GABORI, a bay on the S. E. coaſt of Cape Breton iſland. The entrance into it, which is not more than 20 leagues from the iſles of St. Pierre, is between iſlands and rocks about a league in breadth. The bay is 2 leagues deep, and affords good anchorage.—*Morse.*

GABRIEL, ST an iſland in the great river La Plata, S. America, diſcovered by Sebaſtian Cabot, in the year 1526.—*ib.*

GAGE's *Town*, a ſettlement in Sunbury co. New-Brunſwick; on the lands granted to general Gage, on the W. ſide of St John's river, on the northern ſhore of the bay of Fundy. The general's grant conſiſts of 20,000 acres of land; the up-land of which is in general very bad. There is ſome intervale on the river ſide, on which are a few ſettlers; excluſive of theſe ſettlements, there is very little good land of any kind.—*ib.*

GAGUEDI, a tree peculiar to Lamalmon, in Abyſſinia, is thus deſcribed by Mr Bruce. The leaves are long, and broader as they approach the end. The point is obtuſe. They are of a dead green, not unlike the willow, and placed alternately one above the other on the ſtalk. The calix is compoſed of many broad ſcales lying one above the other, which operates by the preſſure upon one another, and keeps the calix ſhut before the flower arrives at perfection. The flower is monopetolous, or made of one leaf; it is divided at the top into four ſegments; where theſe end, it is covered with a tuſt of down, reſembling hair, and this is the caſe at the top alſo. When the flower is young and unripe, they are laid regularly ſo as to incloſe one another in a circle. As they grow old and expand, they ſeem to loſe their regular form, and become more confuſed, till at laſt, when arrived at its full perfection, they range themſelves parallel to the lips of the calix, and perpendicular to the ſtamina, in the ſame order as a roſe. The common receptacle of the flower is oblong, and very capacious, of a yellow colour, and covered with ſmall leaves like hair. The ſtile is plain, ſimple, and upright, and covered at the bottom with a tuſt of down, and is below the common receptacle of the flower.

Our author ſays that he has obſerved, in the middle of a very hot day, that the flowers unbend themſelves more, the calix ſeems to expand, and the whole flower to turn itſelf towards the ſun in the ſame manner as does the ſun-flower. When the branch is cut, the flower dries, as it were inſtantaneouſly, ſo that it ſeems to contain very little humidity.

GALEN, a military townſhip in the ſtate of New-York, ſituated on Canadaque creek, 12 miles N. W. of the N. end of Cayuga lake, and 13 S. by E. of Great Sodus. It is bounded S. by Junius.—*Morse.*

GALETS, an iſland at the E. end of lake Ontario, and in the ſtate of New-York, 5 miles S. weſtward of Roebuck iſland, 5 northerly of Point Gaverſe, and 31 S. E. of Point au Goelans.—*ib.*

GALETTE, LA, a neck of land in the river St. Lawrence, in Canada. From the point oppoſite to l'iſle de Montreal, a road might be made to Galette, ſo as to ſave 40 leagues of navigation, which the falls

Galibis || Gallan.

render almoſt impracticable, and always very tedious. The land about La Galette is very good; and in two days time a barque may ſail thence to Niagara, with a good wind. La Galette is a league and a half above the fall called les Galots.—*ib.*

GALIBIS, or *Charaibes*, a nation of Indians inhabiting near New-Andaluſia, in S. America; from which the Charaibes of the Weſt-Indies are thought to be deſcended.—*ib.*

GALICIA, an audience in Old Mexico or New-Spain, containing 7 provinces. Guadalaxera is the capital city.—*ib.*

GALIPAGO *Iſles*, the name of ſeveral uninhabited iſles in the South Sea, on both ſides the equator, not far from the coaſt of Terra Firma; belonging to Spain. They lie between 3. N. and 4. S. lat. and between 83. 40. and 89. 30. W. long. There are only 9 of them of any conſiderable ſize; ſome of which are 7 or 8 leagues long, and 3 or 4 broad. Dampier ſaw 14 or 15 of them. The chief of theſe are Norfolk, neareſt the continent, Wenmore among the N. weſternmoſt and Albemarle the weſternmoſt of all. A number of ſmall iſles lie W. from theſe, on both ſides the equator; one of which, Gallego iſland lies in the 1ſt degree of N. lat. and 102 of W. long. Many of theſe iſles are well wooded, and ſome have a deep black mould. Vaſt quantities of the fineſt turtle are to be found among theſe iſlands, where they live the greateſt part of the year; yet they are ſaid to go from thence over to the main to lay their eggs, which is at leaſt 100 leagues diſtant.—*ib.*

GALLAN, St a ſmall iſland on the coaſt of Peru, in lat. 14. S. 5 miles N. of the high land *Morro Veijo*, or Old Man's Head; between which iſland and the high land, is a moſt elegible ſtation to cruize for veſſels bound for Callao, N. or S.—*ib.*

Galliopolis || Galloway.

GALLIOPOLIS, a poſt town in the N. W. territory, ſituated on a bend of the Ohio, and nearly oppoſite to the mouth of the Great Kanhaway. It is ſaid to contain about 100 houſes, all inhabited by French people. It is 140 miles eaſtward of Columbia, 300 S. W. of Pittſburg, and 559 S. W. of Philadelphia. N. lat. 39. 2. W. long 83. 9.

This town is ſaid to be on the decline, their right to the lands not being ſufficiently ſecured.—*ib.*

GALOTS, the loweſt of the falls on the river St Lawrence in Canada. Between the neck of land La Galette and les Galots is an excellent country, and no where can there be ſeen finer foreſts.—*ib.*

Galots, l'isle aux, an iſland in the river St Lawrence, in Canada; 3 leagues beyond l'iſle aux Chevres, in N. lat. 43. 33.—*ib.*

GALLO, an iſland in the province of Popayan, S. America, in N. lat. 2. 40. Captain Dampier ſays it is ſituated in a deep bay, and that off this iſland there is not above 4 or 5 fathom water; but at Segnetta, which is on the N. ſide, a veſſel may ride in deep water, free from any danger. The iſland is high, provided with wood and good water, and having good ſandy bays, where a ſhip may be cleaned.——Alſo, the name of an iſland of the S. ſea, near the coaſt of Peru, which was the firſt place poſſeſſed by the Spaniards, when they attempted the conqueſt of Peru.—*ib.*

GALLOWAY, a townſhip in Glouceſter co. New-Jerſey.—*ib.*

GALVANISM.

1 Galvaniſm improperly called *animal electricity*.

GALVANISM, is the name now commonly given to the influence diſcovered nearly eight years ago by the celebrated Galvani, profeſſor of anatomy at Bologna, and which, by him and ſome other authors, has been called *animal electricity*. We prefer the former name, becauſe we think it by no means proved, that the phenomena diſcovered by Galvani depend either upon the electric fluid, or upon any law of animal life. While that is the caſe, it is ſurely better to diſtinguiſh a new branch of ſcience by the name of the inventor, than to give it an appellation which probably may, and, in our opinion, certainly does, lead to an erroneous theory.

M. Galvani was engaged in a ſet of experiments, the object of which was to demonſtrate, if poſſible, the dependence of muſcular motion upon electricity. In the courſe of this inveſtigation, he had met with ſeveral new and ſtriking appearances which were certainly electrical; ſoon after which, a fortunate accident led to the diſcovery of the phenomena which conſtitute the chief ſubject of this article. The ſtrong reſemblance which theſe bore to the electrical facts which he had before obſerved, led almoſt irreſiſtibly to the concluſion that they all depended upon the ſame cauſe. This opinion he immediately adopted; and his ſubſequent experiments and reaſonings were naturally directed to ſupport it. The ſplendor of his diſcovery dazzled the imaginations of thoſe who proſecuted the enquiry; and for ſome time his theory, in ſo far at leaſt as it attributed the whole to the agency of the electric fluid, was ſanctioned by univerſal approbation. Of late, however, this opinion has rather loſt ground; and there are now many philoſophers who conſider the phenomena as totally unconnected with electricity.

2 Diſcovery of galvaniſm.

3 Object of this article

We propoſe, in the *firſt* place, to enumerate the chief facts which have been aſcertained on the ſubject; we ſhall then enquire, whether or not the cauſe of the appearances be the electric fluid; and, *thirdly*, we ſhall examine how far it has been proved, that this cauſe is neceſſarily connected with animal life.

Whilſt Galvani was one day employed in diſſecting a frog, in a room where ſome of his friends were amuſing themſelves with electrical experiments, one of them having happened to draw a ſpark from the conductor at the ſame time that the profeſſor touched one of the nerves of the animal, its whole body was inſtantly ſhaken by a violent convulſion. Aſtoniſhed at the phenomenon, and at firſt imagining that it might be owing to his having wounded the nerve, he pricked it with the point of his knife, to aſſure himſelf whether or not this was the caſe, but no motion of the frog's body was produced. He now touched the nerve with the inſtrument as at firſt, and directed a ſpark to be taken at the ſame

same time from the machine, on which the contractions were renewed. Upon a third trial, the animal remained motionless; but observing that he held his knife by the handle, which was made of ivory, he changed it for a metallic one, and immediately the movements took place, which never was the case when he used an electric substance.

After having made a great many similar experiments with the electrical machine, he resolved to prosecute the subject with atmospheric electricity. With this view he raised a conductor on the roof of his house, from which he brought an iron wire into his room. To this he attached metal conductors, connected with the nerves of the animals destined to be the subjects of his experiments; and to their legs he fastened wires which reached the floor. These experiments were not confined to frogs alone. Different animals, both of cold and warm blood, were subjected to them; and in all of them considerable movements were excited whenever it lightned. These preceded thunder, and corresponded with its intensity and repetition; and even when no lightning appeared, the movements took place when any stormy cloud passed over the apparatus. That all these appearances were produced by the electric fluid, was obvious.

Having soon after this suspended some frogs from the iron palisades which surrounded his garden, by means of metallic hooks fixed in the spines of their backs, he observed that their muscles contracted frequently and involuntarily as if from a shock of electricity. Not doubting that the contractions depended on the electric fluid, he at first suspected that they were connected with changes in the state of the atmosphere. He soon found, however, that this was not the case; and having varied, in many different ways, the circumstances in which the frogs were placed, he at length discovered that he could produce the movements at pleasure by touching the animals with two different metals, which, at the same time, touched one another either immediately or by the intervention of some other substance capable of conducting electricity.

All the experiments that have yet been made may be reduced to the following, which will give the otherwise uninformed reader a precise notion of the subject.

Lay bare about an inch of a great nerve, leading to any limb or muscle. Let that end of the bared part which is farthest from the limb be in close contact with a bit of zinc. Touch the zinc with a bit of silver, while another part of the silver touches, either the naked nerve, if not dry, or, whether it be dry or not, the limb or muscle to which it leads. Violent contractions are produced in the limb or muscle, but not in any muscle on the other side of the zinc.

Or, touch the bared nerve with a piece of zinc, and touch, with a piece of silver, either the bared nerve, or the limb; no convulsion is observed, till the zinc and silver are also made to touch each other.

4 Has engaged much scientific attention.

A fact so new, illustrated by many experiments and much ingenious reasoning, which Professor Galvani soon published, could not fail to attract the attention of physiologists all over Europe; and the result of a vast number of experiments, equally cruel and surprising, has been from time to time laid before the public by Valli, Fowler, Monro, Volta, Humboldt, and others.

Frogs, unhappily for themselves, have been found the most convenient subjects for these experiments, as they retain their muscular irritability and susceptibility of the galvanic influence very long. Many hours after they have been decapitated, or have had their brain and spinal marrow destroyed, strong convulsions can be produced in them by the application of the metals. A leg separated from the body will often continue capable of excitement for several days. Nay, very distinct movements have been produced in frogs pretty far advanced in the process of putrefaction. Different kinds of fishes, and many other animals both of cold and warm blood, have been subjected to similar experiments, and have exhibited the same phenomena; but the warm blooded animals lose their susceptibility of galvanism, as of every other stimulus, very soon after death.

5 The metals.

Almost any two metals will produce the movements; but, it is believed, the most powerful are the following, in the order in which they are here placed: 1. Zinc; 2. Tin; 3. Lead; in conjunction with, 1. Gold; 2. Silver; 3. Molybdena; 4. Steel; 5. Copper. Upon this point, however, authors are not perfectly agreed.

6 Animal and excitatory arcs.

The process by which these singular phenomena are produced, consists in effecting, by the use of the exciting apparatus, a mutual communication between any two points of contact, more or less distant from one another, in a system of nervous and muscular organs. The sphere of this mutual communication may be regarded as a complete circle, divided into two parts. That part of it which consists of the organs of the animal under the experiment, has been called *the animal arc*; that which is formed by the galvanic instruments has been called *the excitatory arc*. The latter usually consists of more pieces than one; of which some are named *stays*, *braces*, &c. others *communicators*, from their respective uses.

7 Experiments of the French Institute.

A very numerous train of experiments on galvanism has been made by a committee of the Physical and Mathematical Class of the National Institute of France; and as their report comprehends a vast number of the most important facts which are yet known on the subject, we shall present our readers with the substance of it (A).

The immense mass of matter which resulted from the experiments of the committee, is, in their report, presented, not in the order in which the experiments were made, but in a sort of classification, by means of which a more distinct knowledge of the subject is obtained at one view. The facts are arranged under these six heads. *1st*, Results of the different combinations and dispositions of the parts of the *animal arc*. *2d*, Account of what has been observed of the nature and the different dispositions of the *excitatory arc*. *3d*, Circumstances not entering into the composition of the galvanic circle, which, nevertheless, by their influence, modify, alter, or entirely prevent the success of the experiments. *4th*, Means proposed for varying, diminishing, or restoring the sensibility to galvanism. *5th*, Attempts to compare the

(A) The members of the committee were, M. M. Coulomb, Sabbatier, Pelletan, Charles, Fourcroy, Vauquelin, Guyton, *alias* Morveau, and Hallé. M. M. Venturi, De Modene, and M. Humboldt, assisted in the experiment.

the phenomena of galvaniſm with thoſe of electricity. *6th*, Additional experiments, performed by M. Humboldt, in the preſence of the members of the committee; which have a reference to ſeveral of the proofs ſtated in the foregoing articles.

8 On the animal arc.

I. To the number of twenty experiments were made on the *animal arc*. The firſt ſeven of theſe were directed to aſcertain the relations between the nerves and thoſe muſcles over which they are diſtributed. In the laſt thirteen, the nerves were cut aſunder, or ſubjected to ligatures; the ſection or ligature being always between the extremities of the arc. Nerves taken from different animals, or from different parts of the ſame animal, and joined in one and the ſame arc, were among the particular ſubjects of theſe experiments; as were alſo the ſolitary nerve, and the ſolitary muſcle, included between the extremities of the *excitatory arc*. There were interpoſed, too, in the courſe of theſe experiments, portions of nerves, and of muſcles, diſtinct from thoſe parts. And, in ſome of the experiments, the animal was without the ſkin and the epidermis.

The following are inferences which have been deduced from theſe experiments:

9 Inferences.

1. The animal arc may conſiſt either of nerves and muſcles together, or of nerves alone, without muſcles. (B).

2. Nerves are, therefore, the eſſential part of the animal arc; for the muſcles are always more or leſs interſected by the nerves; and are, conſequently, in part, a nervous organ.

3. All the parts of the animal arc muſt be either mutually continuous, or at leaſt contiguous to one another. But even contiguity is ſufficient to enable the galvanic phænomena to take place.

4. The ſection or ligature of a nerve interrupts not the galvanic phænomena, if the parts which are cut aſunder or bound up ſtill remain in cloſe contiguity to one another.

5. No diverſity of the parts forming the animal arc, though theſe be taken from different parts of the ſame animal, or even from different animals, will have power to impair its galvanic ſuſceptibility, provided only that theſe parts be ſtill mutually contiguous.

6. If the *integrity* or galvanic ſuſceptibility of the animal arc be ſuſpended by the ſeparation of any of its parts to ſome diſtance from one another, it may be reſtored by the interpoſition of ſome ſubſtances, not of an animal nature, between the divided parts. Metallic

ſubſtances

(B) We are ſtrongly inclined to doubt the truth of this propoſition. Dr Fowler was at firſt led to think that contractions could be excited in a limb without the metals having any communication with it, except through the medium of the nerve. Recollecting, however, that a very ſmall quantity of moiſture ſerves as a conductor of galvaniſm, he ſuſpected, and our opinion perfectly coincides with his, that in every caſe where contractions are produced in a limb, without any apparent communication between the metals and the muſcles, except through the medium of a nerve, the communication is in fact completed by the moiſture upon the ſurface of the nerve. In this caſe, the animal arc may be conſidered as conſiſting of three pieces, diſpoſed in the following order; the nerve, the muſcle, and the water adhering to the ſurface of the nerve. The latter, indeed, ought rather to be conſidered as a part of the excitatory arc. "When a nerve (ſays Dr Fowler,), which for ſome time has been detached from ſurrounding parts, is either carfully wiped quite dry with a piece of fine muſlin, or (leſt this ſhould be thought to injure its ſtructure) ſuffered to remain ſuſpended till its moiſture has evaporated, no contractions can be excited in the muſcles, to which it is diſtributed, by touching it alone with any two metals in contact with each other; but if it be again moiſtened with a few drops of water, contractions inſtantly take place. And, in this way, by alternately drying and moiſtening the nerve, contractions may at pleaſure be alternately ſuſpended and renewed for a conſiderable time. It may, indeed, be contended, that the moiſture ſoftened, and thus reſtored elaſticity and free expanſion to the dried cellular membrane ſurrounding the fibres, of which the trunk of a nerve is compoſed; and thus, by removing conſtraint, gave free play to their organization.

"But from obſerving, that in every other inſtance where contractions are produced by the mutual contact of the metals, a conducting ſubſtance is interpoſed between them and the muſcles as well as between them and the nerve; I think it would be unphiloſophical not to allow, that, in the inſtance in queſtion, the moiſture, adhering to the ſurface of the nerve, formed that requiſite communication between the metals and the muſcles." We know of no accurate experiment by which it has ever been ſhewn, that contractions can be produced in a limb without a communication being eſtabliſhed between the metals and nerve, and again between the muſcles and the metals, either directly, or through ſome medium capable of conducting galvaniſm.

To remove the only objection which can be made to Dr Fowler's experiment, and of which we have ſeen that he was himſelf aware, namely, that the nerve while dry is incapable of performing its functions, we repeated it in the following manner: A ſmall, but vigorous and lively, male frog was decapitated, and the ſciatic nerve being laid bare from the knee upwards, was cut through where it paſſes out of the pelvis. Fifteen minutes after the head was cut off, the nerve having been cautiouſly ſeparated from the ſurrounding parts, and coated with tinfoil in the uſual manner, a ſilver probe was applied to it and its coating, without any other communication with the muſcles, and ſtrong contractions took place in the leg. The nerve was now very carefully dried with a piece of fine linen, and the probe was applied as before to the tinfoil and the nerve; no movement whatever took place. Things remaining preciſely in this ſituation, one end of the probe being ſtill in contact with the nerve and its coating, the other end was applied to the muſcles of the thigh, and the leg immediately contracted as ſtrongly as ever. Upon moiſtening the nerve, the contractions were again produced by applying the probe to the nerve and tinfoil alone. We find from this experiment, which we have ſeveral times repeated with the utmoſt care, and with the ſame reſult, that the dry nerve retained its functions completely. This appears to us perfectly deciſive of the queſtion.

subſtances are in particular fit for this uſe. But the mutual contiguity of all the ſubſtances entering into the compoſition of the arc muſt ever be carefully preſerved. Mr Humboldt diſcovered that a bit of freſh morel'e *Helvella mitra Linn.*) will ſupply the place of a part of the nerve.

7. The muſcular organs which indicate, by contraction, the preſence of the galvanic influence, are always thoſe in which the nerves of a complete animal arc have their ultimate termination.

From this it follows, that the muſcles affected by galvaniſm are always thoſe correſponding to that extremity of the arc which is the moſt remote from the origin of the nerves of which it is compoſed.

8. When all the nerves of the animal arc originate towards one of its extremities, then only theſe muſcles which correſpond with the oppoſite extremity are ſuſceptible of galvanic convulſions.

9. When an animal arc conſiſts of more than one ſyſtem of different nerves, which have all their origin about the middle of the arc, then will the muſcles of theſe ſeveral ſyſtems of nerves be moved alike at both the extremities of the arc.

10. It ſeems likewiſe to appear, from a variety of theſe experiments, that the opinion of thoſe is inadmiſſible, who aſcribe the phænomena of galvaniſm to the concurrence of two different and reciprocally correſponding influences, one belonging to the nerve, the other to the muſcle, and who compare the relations between the nerve and the muſcle, in theſe phænomena, to thoſe between the interior and the exterior coating of the Leyden phial.

11. It appears, laſtly, that the covering of the epidermis, in the entire animal body, acts as an obſtacle to the deciſive diſplay of the effects of galvaniſm; and that, though from its extreme tenuity, it may not altogether prevent theſe effects, yet it cannot but very materially diminiſh them.

10 Experiments on the excitatory arc.

II. The *Excitatory Arc* is uſually formed of three different pieces made of different metals. Of theſe, one muſt be in contact with the nerve; the other muſt touch the muſcle; and the third muſt form the mean of communication between theſe two. This arrangement, though not indiſpenſably neceſſary, is at leaſt the moſt convenient.

In reſpect to the excitatory arc, the committee examined, 1ſt, The application of metallic ſubſtances to form it: in reſpect to which they endeavoured to aſcertain the number and the diverſity of the pieces of metal, of which this arc may be compoſed; the metallic mixtures or alloys which are capable of being employed for this uſe; the particular degree of the friction of one metal upon another, which is favourable to the exhibition of the phænomena, the different ſtates, in reſpect to galvaniſm, of metals differently mineralized. 2dly, The effects of the uſe of carbonic ſubſtances in forming the excitatory arc. 3dly, The effects in the ſame formation, of bodies, which are either non-conductors, or elſe very imperfect conductors of electricity, ſuch as jet, aſphaltus, ſulphur, amber, ſealing-wax, diamond, &c. 4thly, The conſequences of the interpoſition of water, and of ſubſtances moiſtened with water, between the different parts of the excitatory arc. In forming their excitatory arcs, too, they made themſelves the chord of the arc; they introduced into it animal ſubſtances which had loſt their vitality; they rubbed the ſupporters with the dry fingers, ſo as to mark them with nothing but the traces of the perſpiration from the ſkin. They made, likewiſe, ſome experiments for the purpoſe of aſcertaining the relations between, on the one hand, the extent and magnitude of the ſurfaces of the parts compoſing the arc, and on the other, the effects produced by its energy. From their experiments they have alſo drawn ſome inferences concerning the relative efficiencies of the ſeveral conſtituent parts of the exciting arc. It is impoſſible for us here to relate in detail all this train of experiments. The following corollaries expreſs the ſubſtance of thoſe general truths, which their authors were led to infer from them.

11 Inferences.

1. The excitatory arc poſſeſſes the greateſt power of galvaniſm, when it is compoſed of at leaſt three diſtinct pieces; each of a peculiar nature: the metals, water, and humid ſubſtances, carbonaceous matters, and animal ſubſtances, ſtripped of the epidermis, being the only materials out of which theſe pieces may be formed.

2. Nevertheleſs the excitatory arc appears to be not deſtitute of exciting energy, even when it conſiſts but of one piece or of ſeveral pieces, all of one proper ſubſtance (c). In general it muſt be owned, identity of nature in the conſtituent pieces, and particularly in the ſupports

---

(c) We do not think it has ever been proved, that one piece of metal, or ſeveral pieces of the ſame metal, are capable of forming the excitatory arc. It is admitted on all hands, that the ſlighteſt alloy communicates galvanic energy to a piece of metal; that is, renders it capable of forming the excitatory arc. It is alſo known, that metallic oxyds are much leſs perfect conductors of galvaniſm than their correſponding reguli, to make uſe of an antiquated expreſſion. It appears to us, that in all caſes where one metal appears to act, more eſpecially where friction with the fingers, or breathing on a piece of metal formerly inert, give it galvanic powers; in all theſe caſes, we think it probable that a ſlight degree of oxydation, produced in ſome part of the ſurface of the metal, gives it activity by deſtroying the homogeneity of its nature. We do not find that this circumſtance has been in general ſufficiently attended to. Dr Wells having diſcovered that charcoal acts powerfully as an exciter when applied along with a metal, found that by friction it alſo can be rendered capable of acting ſingly. What change is thus produced in it we can only conjecture; but that it is ſomething which deſtroys the identity of its ſtructure, rendering it in ſome meaſure a heterogeneous ſubſtance, muſt be admitted.

Candour forces us to acknowledge, that in one of M. Humboldt's experiments, it ſeems very difficult to point out any want of homogeneity in the exciting arc. He put into a china cup ſome mercury exactly purified; he placed the whole near a warm ſtove, in order that the entire maſs might aſſume an equal temperature: the ſurface was clear, without the appearance of oxydation, humidity, or duſt. A thigh of a frog, prepared in ſuch a manner supports forming the extremities of the arc, diminishes, in a very sensible manner, its galvanic energy.

3. The slightest difference of nature induced upon the parts, whether by any feeble alloy, or by friction with extraneous substances, is at any time sufficient to communicate to the excitatory arc that full power in which the identity of its composition may have made it defective.

4. As the animal arc is susceptible of being in part made up of metallic substances, or such others as are adapted to enter into the composition of the excitatory arc; so, on the other hand, the excitatory arc admits of being in part formed of these substances which are the proper components of the animal arc.

5. The energies of both the excitatory and the animal arcs are alike suspended by the separation of their component parts, or at least by the separation of these parts to a certain distance.

6. Even the smallest degree of moisture is sufficient to join the parts of the excitatory arc, and to determine their effects upon the animal arc.

7. The influence of the state of the atmosphere, and of surrounding circumstances, upon the success of the experiments of galvanism, is, consequently, very great. In order, therefore, to perform these experiments with due accuracy, the state of the hygrometer, and of other meteorological instruments, must be vigilantly inspected during their progress; and the influence of the persons making the experiment upon the sphere within which it is made, must likewise be carefully attended to.

8. The experiments which were made to ascertain the nature of the animal arc, together with those made upon the excitatory arc, with a view to the comparison of the effects of the flesh of animals, with or without the epidermis, and of the different effects of this epidermis, when it is wet, and when it is dry, appear to suggest to us, that the epidermis is one of those substances which diminish or interrupt the efficacy of the excitatory arc. The epidermis is, as well as the hairs and bristles of animal bodies, among the number of those substances which deserve the appellation of *idioelectrics*.

9. Examine the substances which are fit for the formation of the excitatory arc, and you will find that the greater part of those which have been successfully put to this use are substances capable of acting as conductors of the electrical fluid; but that the substances which interrupt the operation of galvanism are generally such as are well known also to resist the transmission of electricity.

10. Lastly, it appears, that the galvanic energy depends, not only upon the nature and arrangement of the component parts of the excitatory arc, but on their extent too, and on the magnitudes of their transmitting surfaces.

12 Experiments relating to circumstances different from the arcs.

III. The committee appear to have used no less care and discernment in experiments upon those circumstances which, though different from the structure of the galvanic circle and its two constituent arcs, have, however, *a decisive influence upon the exhibition of the phænomena of galvanism*. Some curious observations were made on the differences in the state of the parts exposed to the galvanic action. It was ascertained, that frogs fresh from the ditches did by no means exhibit the same phænomena as those which had been during some days preserved in the house; nor did the limbs of animals, when recently stripped of the skin, present the same appearances as after they had been subjected to a variety of galvanic experiments; nor were the same effects to be produced upon the parts of animal bodies which, after a certain number of trials, had been left for a while at rest, and then taken up again, as upon those which had been subjected to one continued train of experiments. The committee next examined the variations in the success of the experiments upon a strong lively frog, which may be produced by varying the mode in which the *communicator* is carried from the one *supporter* to the other: when the communicator is brought into contact with the supporter, or is withdrawn from actual contact with it; when the *communicator* is brought slowly, or when it is brought rapidly, into contact with the *supporter*; the effects are nearly the same: and a smart convulsion is, in all these cases produced at the moment of the commencement of the mutual contact, or of its cessation. But when the frog is fatigued, the effects are different. These successive experiments likewise affect the results of one another, by means even of their succession solely. And they are also naturally subject to be influenced by the nature of the media amidst which they are performed; such as common air, water, an electrical atmosphere. The following are the inferences which have been deduced from this class of these experiments.

13 Inferences.

1. In many cases the galvanic energy is excited by exercise, is exhausted by continued motion, is renovated by rest.

2. The multiplicity of the causes by which the experiments of galvanism are liable to be influenced to success or failure, is so great, that we cannot, as yet, be too cautious in either rejecting or believing these accounts which we hear of the success of any such experiments; unless when we are able accurately to appreciate all the influencing circumstances.

3. This is remarkably confirmed by a fact, which the committee have related in their paper, and which respects the continuation of the galvanic spasm.

The communicator being supported by the hand, and resting, seemingly, without change of position, still upon

a manner that a crural nerve and a bundle of muscular fibres of the same length hung down separately, was suspended by two silken threads above the mercury. When the nerve alone touched the surface of the metal, no irritation was manifested; but as soon as the muscular bundle and the nerve touched the mercury together, they fell into convulsions so brisk, that the skin was extended as in an attack of tetanus. This is by far the most decisive experiment which has been tried on the same side of the question; but as it must be admitted, that in most cases two metals are absolutely necessary, and that a single metal often derives activity from circumstances so slight, that we could not *a priori* have expected that they were capable of producing any change: we feel ourselves compelled to conclude, that in M. Humboldt's experiment some similar very slight circumstance had escaped unobserved; perhaps some gilding, or ornaments with metallic colours, in a state of oxydation.

upon the same point of contact, there is known to take place a real change in the galvanic contact, although the communicator have remained thus apparently motionless.

From this, it may be farther inferred, that the smallest possible change in the relative situations of the parts of the galvanic circle and the excitatory arc, is capable of producing an effect upon the susceptible animal, and of occasioning mistakes in regard to the success of the experiment, if the utmost care be not taken to notice and estimate every variation that can happen.

4. The truth of the foregoing proposition is farther confirmed by the experiments upon the manner in which the galvanic movements are affected by the advancing or the withdrawing of the communicator. For these experiments fully evince the necessity for the most vigilant observation of every movement in the process of an experiment, not only collectively, but in their succession, and at the different periods of the operation.

5. It should seem that there are, in the formation of the excitatory arc, independently of its modes of acting in the galvanic operations, certain enervating, and certain exciting dispositions; of which some not only augment or diminish the energy in the present instance, but, besides, dispose the animal to a greater or a smaller susceptibility, under subsequent experiments.

6. In order to accuracy of experiment, and to the correct ascertaining of the effects of an experiment, it is of great importance to know the precise state of the animal, the manner in which it has been preserved and sustained to the present moment, the state of the atmosphere, particularly as it is indicated by the hygrometer, by the barometer, the thermometer, and the electrometer.

7. It were to be wished, that in making a statement of experiments of different sorts, these should be arranged in the order of their efficacy, and that there might thus be formed a *galvanic scale*, which should help us to determine the precise degree of the galvanic susceptibility of any animal in this or that particular state or position, should direct us in subjecting every such animal only to experiments suitable to its particular susceptibility; should enable us to estimate, from the *efficacy* or *inefficacy* of our experiments, the galvanic value of the circumstances in which we every day find ourselves, and should enable us to judge when the success or miscarriage of an experiment can afford room for certain conclusions absolutely negative or affirmative.

14 Experiments on the galvanic susceptibility of animal bodies, &c.

IV. In their experiments upon *the means of varying, diminishing, and removing the susceptibility of animal bodies* to the influence of galvanism, the committee examined, 1st, the influence of electricity upon that susceptibility; 2d, the effects of the muscular organs, and of certain liquors, such as alcohol, the oxygenated muriatic acid, the solutions of potash and opium, upon the galvanic properties; 3d, and at the medical school of Paris they made a number of experiments, in order to ascertain what new modifications the galvanic energy undergoes in various cases of suffocation or asphyxia. These last-mentioned experiments were made upon hot-blooded animals, of which some were reduced into the state of asphyxia by submersion, some by strangulation, some by the action of gases, while others were killed *in vacuo* by the discharge of the electric spark. In that suffocation which was produced by sulphurated hydrogenous gas, by carbonic vapours, and by submersion, in which the animal was suspended by the hinder feet, the galvanic susceptibility was entirely destroyed. The galvanic susceptibility was only suspended by suffocation produced by the pure carbonic acid confined under mercury. It was diminished, but not destroyed, in those cases of suffocation, which were occasioned by sulphurated hydrogenous gas that had lost a portion of its sulphur by gas ammoniac, gas azote, or such gases as had been exhausted of their pure air by respiration; and the same thing was found to take place in animals which had perished by total submersion. But the galvanic susceptibility survived unaltered in suffocations brought on by submersion in mercury, by pure hydrogenous gas, by carbonated hydrogenous gas, by oxygenated muriatic acid, by sulphureous acid; as also when the suffocation was occasioned by strangulation, by the abstraction of the air in the air-pump, or by discharges from an electrical battery. The results of the experiments at the medical school suggested the following reflections:

15 Reflections

1. Though it be true that all cases of suffocation resemble one another in the privation of respirable air, and in the suspension of the functions of respiration, and of the circulation of the blood; yet, in their other circumstances, they are subject to great differences, arising from diversity of nature in the substances by which they are occasioned.

2. Of these causes, some appear to act with a more thorough efficacy, penetrating at once all parts of the nervous and muscular systems. Others again seem to act but superficially, producing only pulmonary asphyxia, with its immediate effects.

3. One of the most remarkable changes not confined to the organs of respiration, consists in the alterations produced on the galvanic susceptibility. In that respect the various cases of asphyxia differ greatly one from another.

4. The state of the irritability of the muscles, when examined by means of bodies, the mechanical action of which causes the muscles to contract by irritating them, is far from always corresponding to the state of their galvanic susceptibility.

5. Lastly, the causes of suffocation or asphyxia, do not act upon all parts of the muscular system in the same manner; but the heart is very often found in a state extremely different from that of the other muscles.

16 Comparison of the phenomena of galvanism with those of electricity.

V. *The comparison between the phænomena of galvanism and those of electricity* is perhaps one of the most interesting objects of attention in the whole body of animal physiology. It is well known that Galvani was accidentally led to his discovery by observing the motions of some frogs, at a certain distance from an electrical machine discharging sparks. The committee from the institute made, therefore, some attempts to ascertain the relations between electricity and galvanism. Having first paid due attention to the susceptibility of animals toward the influence of electricity, they then sought to discover to what precise degree animals divested of the natural covering of the epidermis were liable to be affected by the variations of the electrical fluid in the atmosphere around them. Next, comparing the susceptibility of electricity with the susceptibility of of galvaniſm, they perceived that quantities of the electrical fluid, ſuch as are ſtill capable of being very accurately meaſured by the electrometer, are, however, often too weak to act upon a frog that retains the moſt perfect ſenſibility to all the energy of galvaniſm. The members of the committee purpoſe to proſecute farther their experiments upon this part of the ſubject.

17 Reſults of ſome experiments by Humboldt.

VI. The following are the general reſults of the experiments made by M. Humboldt in the preſence of the committee:

1. There is no truth in the aſſertion of certain phyſiologiſts, that the experiments of galvaniſm fail when tried upon the heart and thoſe other muſcles of which the contractions depend not upon volition; for theſe organs have been found to be actually ſubject to the influence of galvaniſm (D).

2. The effects of galvaniſm are liable to be interrupted by the conſtriction of a nerve, whenever both the nerve and the conſtricting ligature are enveloped in the fleſh of the animal body (E).

3. The powers of the exciting arc may be renovated or deſtroyed, even though its ſupporters remain the ſame, and although the extremities of the arc be unchanged. Only the relations of the intermediate matters require to be altered.

4. There are atmoſpheres of galvaniſm.

5. There are ſubſtances which, though in an eminent manner conductors of electricity, yet interrupt the motions of galvaniſm.

M. Humboldt had performed alſo other experiments, which, when he attempted to repeat them before the committee, could not be brought to ſucceed, on account, as was ſuppoſed, of the ſeaſon of the year.

Such are the principal reſults of this valuable train of experiments upon galvaniſm. From them, our readers will perceive that this intereſting ſubject is ſtill very imperfectly underſtood, and will form ſome idea of the importance of the diſcoveries which a diligent proſecution of it promiſes to the philoſopher and the phyſician.

18 Effects of galvaniſm upon ſome of the organs of ſenſe.

The effects of galvaniſm upon ſome of the organs of ſenſe are no leſs ſtriking than thoſe which we have ſeen it capable of producing upon the muſcles.

If the upper and under ſurfaces of the tongue be coated with two different metals, and theſe be brought into contact with each other, a peculiar ſenſation, reſembling taſte, is produced in the tongue the moment that the metals touch each other. With the greater number of metals this ſenſation is ſcarcely perceptible; but with zinc and gold, zinc and ſilver, or zinc and molybdena, it is very ſtrong and diſagreeable. Dr Fowler thinks it is ſtrongeſt with zinc and gold; to us it appears a good deal ſtronger with zinc and ſilver. It is ſenſibly ſtronger when the zinc is applied to the upper, and the ſilver to the under ſurface of the tongue, than when this order is inverted. The ſenſation is moſt diſtinct when the tongue is of the ordinary temperature, and the metals of the ſame temperature with the tongue, Any conſiderable increaſe or diminution of heat in either greatly leſſens the effect. Mr Sulzer of Berlin, in his *Theorie des Plaiſirs*, p. 155 (publiſhed in 1767), takes notice of the diſagreeable taſte produced by ſilver and lead in contact upon the tongue. This is the firſt inſtance of galvaniſm that has been made public.

To enſure complete ſucceſs to the experiment, the metals ought to be allowed to remain ſome time in contact with the tongue before they are made to touch each other, that the taſte of the metals themſelves may not be confounded with the ſenſation produced by their mere contact. Whatever has a tendency to blunt the ſenſibility of the tongue, as opium, alcohol, acids, and the like, diminiſhes the effect of the metals.

It is difficult to deſcribe the ſenſation thus produced accurately. It has been called *ſubacid*; but we think it more nearly reſembles the effect produced by allowing a grain or two of nitre to lie upon the tongue for ſome time, than any other taſte with which we are acquainted. Joined to this, there is evidently a metallic taſte, which varies with the metal employed; but we are inclined to conſider this as the ordinary effect of the metals upon the tongue, which cannot be perfectly diſtinguiſhed from that occaſioned by their mutual contact.

This taſte can alſo be produced by applying one of the metals to the tongue, and the other to any part of the Schneiderian membrane. Profeſſor Robiſon has made many experiments of this kind, the reſult of which is contained in a letter to Dr Fowler. "I find (ſays he), that if a piece of zinc be applied to the tongue, and be in contact with a piece of ſilver which touches any part of the lining of the mouth, noſtrils, ear, urethra, or anus, the ſenſation reſembling taſte is felt on the tongue. If the experiment be inverted, by applying the ſilver to the tongue, the irritation produced by the zinc is not ſenſible, except in the mouth and the urethra, and is very ſlight. I find the irritation by the zinc ſtrongeſt when the contact is very ſlight, and confined to a narrow ſpace, and when the contact of the ſilver is very extenſive, as when the tongue is applied to the cavity of a ſilver ſpoon. When the zinc touches in an extenſive ſurface, the irritation produced by a narrow contact of the ſilver is very diſtinct, eſpecially on the upper ſide of the tongue, and along its margin. This irritation ſeems to be mere pungency, without any reſemblance to taſte, and it leaves a laſting impreſſion like that made by cauſtic alkali.

"When a rod of zinc, and one of ſilver, are applied to the root of the mouth, as far back as poſſible, the irritations produced by bringing their outer ends into contact are very ſtrong, and that by the zinc reſembles taſte in the ſame manner as when applied to the tongue."

M. Volta found, that when a tin cup, filled with an alkaline liquor, is held in one or both hands previouſly moiſtened with water, if the point of the tongue is dipped in the liquor, an acid taſte is perceived. This is at firſt diſtinct and pretty ſtrong, but gradually yields to the alkaline taſte of the liquor. The acid taſte is ſtill more remarkable, when, inſtead of an alkaline liquor, an inſipid mucilage is made uſe of. The ſame philoſopher found, that when a cup made of tin, or what is better, of zinc, was filled with water, and placed upon a ſilver ſupport, if the point of the tongue was applied to the water, it was found quite inſipid, till he laid hold of the ſilver ſupport, with the hand well

(D) This was demonſtrated ſix years ago by Dr Fowler.

(E) Dr Valli made this obſervation ſoon after the diſcovery of galvaniſm.

well moistened, when a very distinct and very strong acid taste was immediately perceived.

If one of the metals be applied to the tongue, and the other to the ball of the eye, a pale luminous flash is perceived when they are brought into contact with each other, and the sensation resembling taste is at the same time produced in the tongue. A flash is, in like manner, produced when one of the metals is applied to the eye, and the other to any part of the palate, fauces, or inside of the cheek. This experiment requires a good deal of attention in the performance; care must be taken not to press the piece of metal against the ball of the eye, lest a flash should be produced by the mere mechanical pressure. It should be cautiously introduced between the eye-lids, till it just touch any part of the ball; and it should be allowed to remain in that situation for some time before it is brought into contact with the other piece of metal, that the parts may be so far accustomed to it as to admit of the sensations produced being properly attended to. The experiment succeeds very well with tin and silver; but the flash is more bright when zinc and gold are used. The piece of metal which is applied to the ball of the eye must be finely polished, otherwise the mechanical irritation is sometimes so great as to prevent the flash from being perceived. Dr Robison has observed, that the brightness of the flash corresponds with the extent of contact of the metal with the tongue, palate, fauces, or cheek.

If a piece of one of the metals be placed as high up as possible between the gums and the upper lip, and the other in a similar situation with respect to the under lip, a very vivid flash of light is observed at the moment that they are brought into contact, and another at the instant of their separation. While they remain in contact, no flash is observed.

When a rod of silver is thrust as far as possible up one of the nostrils, and then brought into contact with a piece of zinc placed upon the tongue, a very strong flash of light is produced in the corresponding eye at the instant of contact. We have sometimes imagined, that the flash in this experiment was produced before the metals actually touched; but in this we may have been deceived.

The following curious experiment was first made by Professor Robison: "Put a plate of zinc into one cheek, and a plate of silver (a crown piece) into the other, at a little distance from each other. Apply the cheeks to them as extensively as possible. Thrust in a rod of zinc between the zinc and the cheek, and a rod of silver between the silver and the other cheek. Bring their outer ends slowly into contact, and a smart convulsive twitch will be felt in the parts of the gums situated between them, accompanied by bright flashes in the eyes. And these will be distinctly perceived before contact, and a second time on separating the ends of the rods, or when they have again attained what may be called *the striking distance*. If the rods be alternated, no effect whatever is produced."—The flashes produced in this last experiment are rather more vivid than any which we have been able to excite by the other methods. The convulsive twitches are very distinct, and somewhat painful, but quite different from the sensation produced by an electric shock. If the edges of the tongue be allowed to touch the plates of metal in the cheeks, the sensation resembling taste is felt very strongly; but this does not in the least impair the other effects of the experiment.

No method has yet, we believe, been discovered of applying the galvanic influence so as to affect the senses of smelling or hearing. We have tried many experiments with this view, chiefly on the organs of smelling, but hitherto without any success (F). Neither has the sense of touch been affected by it, unless, indeed, the following experiment be considered in that view: Let a small portion of the cuticle be removed from any part of the body by a sharp knife, and carry the incision to such a depth that the blood shall just begin to ooze from the cutis vera. Let a piece of zinc be applied here, and a piece of silver to the tongue; when they are brought into contact, a very smart irritation will be felt at the wound.

Some very singular facts of this kind have been discovered by M. Humboldt, who had the resolution to make himself the subject of many well-devised experiments. One of the most remarkable of these is the following: He caused two blistering plasters to be applied on the deltoid muscle of both his own shoulders. When the left blister was opened, a liquor flowed out, which left no other appearance on the skin than a slight varnish, which disappeared by washing. The wound was afterwards left to dry up: this precaution was necessary, in order that the acrid humour which the galvanic irritation would produce, might not be attributed to the idiosyncrisis of the vessels. This painful operation was scarcely commenced on the wound, by the application of zinc and silver, before the serous humour was discharged in abundance; its colour became visibly dark in a few seconds, and left on the parts of the skin where it passed traces of a brown inflamed red. This humour having descended towards the pit of the stomach, and stopped there, caused a redness of more than an inch in surface. The humour, when traced along the epidermis, left stains, which, after having been washed, appeared of a bluish red. The inflamed places, having been imprudently washed with cold water, increased so much in colour and extent, that M. Humboldt, as well as his physician, Dr Schalleru, who assisted at these experiments, entertained some apprehension for the consequences.

Having now taken notice of the principal facts that are hitherto known in galvanism, we proceed to consider some of the leading opinions on the subject.

19 Phenomena of galvanism supposed to result from electricity;

The first writers upon the discovery of Galvani seem almost universally to have taken it for granted, that the phenomena

(F) Professor Robison has long ago observed, that the flavour of a pinch of snuff taken from a box made of tin-plate, which has been long in use, so that the tin coating is removed in many places, is extremely different from that of snuff when taken from a new box, or a box lined with tinfoil. The same difference is observed when we rub a piece of pure tin, or of pure iron and a half worn tinned plate, with the finger. Also, if we rub a cast-steel razor, and a common table knife consisting of iron and steel welded together. This is surely owing to a cause of the same kind.

phenomena depend on the electric fluid; and leaving this very important queſtion behind them, proceeded to explain how this fluid produces ſuch effects. The celebrated diſcoverer of this influence himſelf conſiders a muſcle as the perfect prototype of a Leyden phial. When a muſcle contracts, upon a connection being formed, by means of one or more metals between its external ſurface and the nerve which penetrates it, M. Galvani contends, that, previouſly to this effect, the inner and outer parts of the muſcle contain different quantities of the electric fluid; that the nerve is conſequently in the ſame ſtate, with reſpect to that fluid, as the internal ſubſtance of the muſcle; and that, upon the application of one or more metals between its outer ſurface and the nerve, an electrical diſcharge takes place, which is the cauſe of the contraction of the muſcle. Thus the nerve is ſuppoſed to perform the office of the wire connected with the internal ſurface of the phial; and the excitatory arc is conſidered merely as a conductor.

This theory appears to us juſt as incapable of explaining the phenomena of galvaniſm as it is inconſiſtent with the known laws which regulate the motions of the electric fluid. We ſhall not conſider it minutely; for we hope it will ſoon appear highly probable, if not certain, that the electric fluid has no ſhare in the production of the phenomena in queſtion. If this be the caſe, all the different modifications of that theory muſt of courſe fall to the ground. At preſent we ſhall content ourſelves with aſking the following queſtions:

20 This ſuppoſition ill founded.

1. How is it poſſible for the electric fluid to be condenſed in a muſcle, which is wholly ſurrounded by ſubſtances capable of conducting that fluid?

2. If we ſuppoſe there is ſome non-deſcript non-conducting ſubſtance placed between the external and internal parts of a muſcle, which may admit of the one being poſitively, and the other negatively electrified at the ſame time; how comes it to paſs that a diſcharge does not take place, and a conſequent contraction enſue, when any ſubſtance whatever, capable of conducting the electric fluid, is interpoſed between the nerve and the external ſurface of the muſcle? For example, when the nerve and muſcle are laid bare, and the animal thrown into water; or when the nerve is cut through, and the end applied to the external ſurface of the muſcles.

3. How does it happen, when one diſcharge actually takes place, in conſequence of the application of the excitatory arc, that the balance is not inſtantly reſtored? That this does not happen, appears by the ſame muſcle and nerve being capable of producing many hundreds of ſimilar, and equally ſtrong diſcharges, without any apparent means of the equilibrium being again diſturbed.

We have never ſeen any anſwers to theſe queſtions which appeared to us at all ſatisfactory; and till we have ſeen them anſwered, we muſt be excuſed for diſbelieving M. Galvani's theory.

One of the earlieſt writers, and one of the moſt aſſiduous inveſtigators of the phenomena of galvaniſm, is Dr Valli. He differs in opinion from Galvani upon ſeveral points; but agrees with him in thinking electricity and galvaniſm the ſame. Let us conſider the proofs by which he ſupports this doctrine.

"I have aſſerted (ſays he) that the nervous fluid is the ſame with electricity, and with good reaſon; for

"Subſtances which conduct electricity are conductors likewiſe of the nervous fluid. 21 Proofs by which Valli endeavours to ſupport it,

"Subſtances which are not conductors of electricity do not conduct the nervous fluid.

"Non-conducting bodies, which acquire by heat the property of conducting electricity, preſerve it likewiſe for the nervous fluid.

"Cold, at a certain degree, renders water a non-conductor of electricity, as well as of the nervous fluid.

"The velocity of the nervous fluid is, as far as we can calculate, the ſame with that of electricity.

"The obſtacles which the nerves, under certain circumſtances oppoſe to electricity, they preſent likewiſe to the nervous fluid.

"Attraction is a property of the electric fluid, and this attraction has been diſcovered in the nervous fluid.

"We here ſee the greateſt analogy between theſe fluids; nay, I may even add, the characters of their identity."

That there is a conſiderable analogy between ſome of the effects of the electric fluid and ſome of the phenomena of galvaniſm, we readily admit; but that "the characters of their identity" are any where to be found, we abſolutely deny. In the above paſſage, Dr Valli conſiders it as certain, that the nervous fluid is the cauſe of the phenomena diſcovered by Galvani. But it has never been demonſtrated irrefragably, that any ſuch thing as a nervous fluid exiſts, and ſtill leſs that this is the ſame with the influence diſcovered by Galvani.

That bodies are, in general, conductors or non-conductors of galvaniſm, according as they are conductors or non-conductors of electricity, we believe to be true: but this rule is by no means without exception, as it certainly would be, if galvaniſm and electricity were the ſame. There is an experiment of Dr Fowler's, which ſeems to ſhew, that water is a more powerful conductor of galvaniſm than mercury; though the reverſe is generally allowed as to electricity. 22 Inconcluſive and

If the abdomen of a frog be filled with water, and a ſilver probe paſſed through it ſo as to touch the ſciatic nerves, no contractions are produced; neither do they appear when the probe is touched above the ſurface of the water with a piece of zinc. But if the zinc be applied to the probe at the ſurface of the water, contractions are produced as vigorous as if both the metals touched the nerve. Here the water ſerves as a conducting medium between the nerves and the point where the metals touch each other: but if the abdomen be filled with mercury inſtead of water, no contractions are produced by applying the ſilver probe to the nerves, and touching the probe with the zinc at the ſurface of the mercury. We do not ſee how this experiment can be accounted for, except by allowing that water is a more powerful conductor of galvaniſm than mercury.

If this experiment ſhould be thought inconcluſive, we have the authority of M. Humboldt, and of the committee of the National Inſtitute of France, for ſaying, that there are ſubſtances which, though in an eminent manner conductors of electricity, yet interrupt the motions of galvaniſm. This is certainly ſufficient to take away all weight from Dr Valli's two firſt reaſons for conſidering theſe two fluids as the ſame, viz. that all conductors of electricity are likewiſe conductors of galvaniſm; and that all bodies which do not conduct the former are alſo non conductors of the latter. Theſe two are by far the most important of his reasons; and if they were true in their full extent, they would certainly shew a very striking analogy, though they would by no means deserve the appellation of "characters of identity."

As to the Doctor's two next propositions, which regard the effects of heat and cold in rendering bodies conductors or non-conductors, they are, in fact, only branches of the two first; and as we have seen that these are not universally true, we might admit that they are correct in this particular without weakening our argument. For this reason we shall not consider them minutely; but we may observe that Dr Fowler's experiments shew, that boiling water, and water cooled down to the freezing point, both conduct this influence as well as water at the ordinary temperature of the atmosphere. If any change in the conducting power takes place beyond these points, it may with greater probability be ascribed to the changes of form which the water undergoes than to the increase or diminution of its temperature.

We confess ourselves perfectly ignorant of any data upon which Dr Valli could found a calculation, the result of which could shew that the velocity of the nervous fluid is the same with that of electricity. Suppose we should take it into our heads to assert that the velocity of galvanism is the same with that of light, we apprehend our author could not easily demonstrate the contrary. Neither, in all probability, would he consider this assertion of ours as a sufficient proof that galvanism and light are the same.

With regard to the next proposition, that "the obstacles which the nerves, under certain circumstances, oppose to electricity, they present likewise to the nervous fluid;" we may remark, that any obstacle which destroys the functions of a nerve completely, will prevent the muscles which are supplied by that nerve from contracting upon the application of any stimulus whatever (G). It does not, however, by any means follow, that the passage of either the galvanic or the electric fluid is prevented. The nerves may still be very good conductors of both, though the muscle is deprived of all power of contracting. That there are obstacles, however, which the nerves, under certain circumstances, present to the passage of electricity, but which they do not under the same circumstances present to galvanism, we think abundantly demonstrated by Dr Valli's own experiments.

23 Inconsistent with his own experiments,

"I have frequently observed (says he) that the legs, of which the nerves had been tied at a certain distance from the muscles, did not feel the action of a certain quantity of artificial electricity, although they were violently convulsed by exciting that which was inherent and peculiar to them." What then was the cause of the difference observed in these cases between the effects of galvanism and electricity? Was it, that the quantity or degree of the former exceeded that of the latter? Be it so.

Dr Valli informs us, that in his experiments, an electric charge which could flash through a thickness of air equal to .035 of an inch, produced no movement in the leg of a frog of which the crural nerve was tied, while the other leg, of which the nerve was left free, underwent considerable movements.

That the influence discovered by Galvani can pass through an exceeding thin plate of air, is certain, as it is transmitted from link to link of a chain, where no considerable force is used to bring the links into contact. Dr Robison's experiment, too, in which the flashes of light are distinctly observed before the rods of silver and zinc touch each other, is another proof of the same fact; and, if we be not deceived, the same thing takes place when a rod of silver thrust up the nostril is applied to a piece of zinc in contact with the tongue. But that it will only pass through an exceeding thin plate of air, any man may convince himself by an experiment, first tried by Dr Fowler, which is easily repeated. If a stick of sealing-wax be coated with tinfoil, it will be found a very good conductor; but if, with a sharp pen knife, an almost imperceptible division be made across the tinfoil, even this interruption of continuity in the conductor will be found sufficient effectually to bar the passage of galvanism.

We find, then, that a quantity of the electric fluid which can pass through a plate of air of the thickness of .035 of an inch, is obstructed by a ligature upon a nerve, while the galvanic influence passes readily along a nerve included in a ligature, but is obstructed completely by making an almost imperceptible division in a good conductor. The plate of air in this case surely is not near .035 of an inch in thickness. It results incontestibly, from a comparison of these two experiments, that there is, between these two agents, some other difference besides the mere degree of intensity.

We come now to the last reason which our author assigns for his belief that galvanism, or, as he chooses to call it, the *nervous fluid*, is the same with electricity. It will be found a very important one. That property by which bodies charged with the electric fluid attract or repel other bodies, according as they are in the same or the opposite state of electricity from themselves, is so striking, and at the same time so universal, that it has been very properly adopted as the measure of this fluid. If it were true, then, that the galvanic influence possessed the same properties of attraction and repulsion as the electric fluid, this circumstance would certainly increase the analogy between them very much. As we have already seen, however, that they differ in other essential points, even if it were true that they agreed in this, it could constitute no proof of their identity. But if, on the other hand, we should find, that this assertion of our author is founded on error, and that the galvanic influence possesses in no degree whatever those properties of attraction and repulsion which have always been justly considered as essential characteristics of the electric fluid, we shall then be fully justified in asserting, that these two agents, however much they may resemble each other in some less important particulars, are in their nature totally distinct and unconnected.

Let

(G) We do not here mean that contraction which muscles are susceptible of long after death, upon having their fibres mechanically irritated, which is produced by what physiologists have called the *vis insita*, and which is perfectly known to our cooks, as it was to their predecessors in the Roman kitchens, as the foundation of the art of crimping. We at present confine ourselves to contraction produced through the medium of the nerves.

24 And with the knowledge of electricity. Let us examine the proofs by which Dr Valli's assertion is supported. He tells us, that he observed the hairs of a mouse, attached to the nerves of frogs, by the tinfoil with which he surrounded them, alternately attracted and repelled by each other, whenever another metal was so applied as to excite contractions in the frogs. We are very far from meaning to insinuate that Dr Valli did not see, or think he saw, what he thus describes; but that the motion of the hairs must have arisen from some cause, different from that to which he ascribed it, cannot admit of a doubt; for hairs, in such a state of electricity as he supposes, never attract, but always repel each other.

Dr Fowler, who has paid particular attention to this part of his subject, has many times repeated this experiment, both in the manner described by Dr Valli and with every variation in the disposition of the hairs which he could devise: but whether they were placed on the metals, the nerves, or the muscles, or upon all at the same time, he has never in any instance been able to observe them agitated in the slightest degree. He has made similar experiments upon a dog, and upon a large and lively skate, by disposing, in the same way that Valli did the hairs of a mouse, flakes of the finest flax, swan-down, and gold leaf: but although the contractions produced in the skate, by the contact of the metals, were so strong as to make the animal bound from the table, not the least appearance of electricity was indicated. He next suspended from a stick of glass, fixed in the cieling of a close room, some threads, five feet in length, of the flax used in the former experiment; and brought some frogs recently killed, and insulated upon glass, as near to them as possible without touching: but the threads were in no wise affected by the contractions produced in the frogs.

25 Reasoning of Dr Wells on the same subject, In a very ingenious paper upon galvanism by Dr Wells, which is published in the London Philosophical Transactions for 1795, that gentleman maintains the opinion, that the influence discovered by Galvani is electrical. He admits, that it is not attended with those appearances of attraction and repulsion which are held to be the tests of the presence of electricity; but he contends, that "neither ought signs of attraction and repulsion to be in this case presented on the supposition that the influence is electrical; since it is necessary, for the exhibition of such appearances, that bodies, after becoming electrical, should remain so during some sensible portion of time; it being well known, for example, that the passage of the charge of a Leyden phial, from one of its surfaces to the other, does not affect the most delicate electrometer, suspended from a wire, or other substance, which forms the communication between them."

26 Inconclusive likewise. That the charge of a Leyden phial does not, in passing along a wire, affect an electrometer, is certain; and it is equally true, that we have no means of applying an electrometer to a quantity of galvanism in a state of rest in a body. If this influence ever exists in such a state, we have no test by which we can discover its presence; and it is only from the effects which it produces *in transitu* that we know of its existence. But the electric fluid, in passing from link to link of a chain, sensibly affects an electrometer; and in Dr Fowler's experiment with the skate, for example, as more than one piece of metal is employed as an exciter, the fluid, in passing from one piece to another, should have affected the light substances which were placed upon them. This appears to us a sufficient answer to the objection started by Dr Wells: but the same objection having been lately made to us by a gentleman from whom we shall always receive every suggestion with uncommon deference, we thought it worth while to try the following experiment:

Three hours after a frog had been decapitated, it shewed strong signs of galvanic susceptibility. One of the sciatic nerves being coated with tinfoil in the usual manner, the leg was laid upon a plate of zinc. A gentleman was desired to lay hold of the nerve and its coating with the fingers of one hand, which had been previously dipped in water, while with the other hand, also wet, he held the end of a small brass chain about two inches in length. Another gentleman now took hold of the other end of the chain, and with a silver probe, held in his other hand, touched the plate of zinc. The influence being thus made to pass through the chain, the leg contracted vigorously; but a very sensible electrometer, held so near to the chain as almost to touch it, was neither attracted nor repelled. In performing this experiment, it was necessary to have the hands wet, as the dry cuticle tends much to obstruct the passage of galvanism; but the utmost care was taken that the chain should be perfectly dry, otherwise the influence might have been transmitted by the moisture upon its surface without passing through the chain itself.

To avoid the possibility of this happening, the experiment was varied in the following manner: The frog's leg was laid upon a plate of zinc, and the nerve upon a plate of silver. A gentleman now took a silver probe, and one end of the brass chain in contact with it, in one hand; and in the other hand he held the other end of the chain in contact with a rod of zinc. He now touched the silver plate with the rod of silver, and the zinc plate with the rod of zinc. As the influence was not now to be made to pass through his body, there was no necessity for his hands being wet; the whole excitatory arc was therefore made completely dry. In this way very strong contractions were excited in the leg, and still the electrometer was not affected in the smallest degree when brought near the chain.

It is proper to observe, that Dr Valli, in his assertion that attraction is a property of galvanism, does not rest entirely upon his own observation; a committee of the Academy of Sciences at Paris performed the following experiment along with him: "They placed a prepared frog in a vessel which contained the electrometer of M. Coulomb, charged negatively and positively by turns. In both cases, in exciting the animal in the common way, the ball of the electrometer was attracted." It appears to us that Dr Valli and the committee have been deceived, by the friction produced by the motion of the animals under their experiments having excited so much electricity as to affect the electrometer. The first time we tried the experiment abovementioned with the brass chain, we were almost misled by a similar circumstance. Instead of an artificial electrometer, which we happened not to have at hand, we made use of a very long and slender human hair; and we found that it was strongly attracted by the chain. Upon an attentive examination, however, we found that this did not arise from the action of the influence passing through the chain, but from the state of the hair itself, which was ſo highly electrical as to be ſtrongly attracted by every conducting ſubſtance which it approached. Upon ſubſtituting another hair, which ſhewed no mark of being either poſitively or negatively electrified, it was neither attracted nor repelled by the chain. From the above, or ſome ſimilar circumſtance, it is probable that Dr Valli's miſtake has originated; but we are confident, that whoever will repeat the experiment with ſufficient attention, will find the reſult preciſely as we have deſcribed it.

Perhaps it may ſtill be ſaid, that although we have never been able to diſcover attraction and repulſion as properties of galvaniſm, this may ariſe from our not being able to accumulate this influence in ſufficient quantity. To this reaſoning, if reaſoning it can be called, we oppoſe the following conſiderations, which ſtate a diſſimilarity in the phenomena of electricity and galvaniſm, that ſeems abſolutely irreconcilable with the identity of the cauſe.

27 Demonſtration, that the phenomena of galvaniſm and of electricity reſult not from the ſame cauſe.

Nothing is more completely eſtabliſhed in the ſcience of electricity than this, that all thoſe appearances which we call *attractions*, *repulſions*, *abſtractions*, and *accumulation of electric fluid*, are preciſely ſimilar to what would be the appearances, if electricity were a fluid, whoſe particles repel each other, and attract the particles of other matter, according to a certain law (See Electricity, *Suppl.*). Of all thoſe phenomena, the moſt remarkable is the accumulation of electric energy (to give it no more definite name), by means of thin idio-electrics, coated with non-electrics; ſuch, namely, as are exhibited by the Leyden phial, the condenſer, the doubler, &c.

If the phenomena of galvaniſm are produced by the paſſage of electric fluid from one extremity of the excitatory arc to the other, this paſſage will be regulated by the known laws of electricity. It may therefore be accumulated (*in tranſitu*) by means of an apparatus ſimilar to the coated pane, or to the condenſer. Profeſſor Robiſon, with this view, made the following experiments:

1. He made a part of the conductor to his condenſer, or collector of atmoſpheric electricity, conſiſt of a long glaſs rod, on one ſide of which was faſtened (with varniſh) a very narrow ſlip of tinfoil; there was a fine point at one end of this rod, and a gold leaf electrometer at the other. This apparatus was inſulated at one end of a room 19 feet long, having a window in the middle of each ſide. A ſmall electric machine was placed at the other end. On a dry day, with a gentle breeze in a direction acroſs the room, both windows were opened a little way, ſo that there was a continual ſtream of air acroſs the room. The machine was worked; and after a ſhort time had elapſed, the electrometer began to diverge, gradually opened, and at laſt ſtruck the conducting ſlips on each ſide, and then collapſed, and again began to diverge. The windows were ſhut; and immediately, without working the machine, the electrometer diverged rapidly, and touched the ſides of the phial every minute and half. This continued ſo long, that there ſeemed to be no end to it. The Profeſſor now made a cut acroſs the tinfoil with a very ſharp knife; the electrometer now diverged very feebly, and 7½ minutes elapſed before it touched the ſides. He paſſed the knife a ſecond time through the cut. This widened it (though ſcarcely ſenſible to the eye), becauſe the knife had been blunted by the glaſs in the firſt operation. All divergency of the electrometer was now at an end; and although the machine was worked till the electric ſmell was ſenſible at the door to a perſon who happened to come in at this time, no tendency to divergence was obſerved. (*N. B.* the top of the electrometer had no conducting ſubſtance about it, except the ſlip of tinfoil).

The cut, being examined with a microſcope furniſhed with a micrometer, was $\frac{31}{1000}$th of an inch. It was now filled up, by binding over it another ſlip of tinfoil. A plate of talc, whoſe thickneſs did not exceed the 900th of an inch, was coated on one ſide in a circle of 1½ inch diameter. The electrometer was removed, and the coated ſide of the talc was put into cloſe contact with the ſlip of tinfoil on the glaſs rod. A ſtand of tin, whoſe top was a plate of 1½ inch diameter, ſmeared over with mercury, was placed in contact with the other ſide of the talc, and they were preſſed into very cloſe and continuous contact.

The machine being now worked, the coated talc received a charge in about 5 minutes ſufficient to give a very ſmart ſhock: and this was repeated with great regularity every five or ſix minutes. The windows were now thrown open, and the room cleared of its former contents of air, till none of thoſe preſent could perceive any electric ſmell. The machine was now worked again. But after half an hour, only a very faint twitch was felt; but enough to ſhew that an accumulation was taking place. The windows were now half ſhut. After working the machine about five minutes, a faint twitch was obtained; after a quarter of an hour more, there was a moderate ſhock.

In this ſtate of things, the apparatus was examined as a condenſer, by firſt taking out the ſharp point by an inſulating handle, and then removing the tin ſtand. Examined in this way, it appeared plainly that, even when all the windows were open, the accumulation began almoſt as ſoon as the machine was worked. Nay, it was found, on another day equally favourable, that a plate of talc $\frac{47}{1000}$ or $\frac{50}{1000}$ of an inch thick, took a charge, although a cut of $\frac{31}{1000}$ wide did not allow the electricity to fly acroſs it. This is perfectly ſimilar to all our experiments on coated glaſs. The thickneſs which admits an accumulation is almoſt incomparably greater than the diſtance to which a ſpark will fly, or a concuſſion is producible, in the ſame intenſity of electricity.

2. The above deſcribed apparatus was inſulated, and a wire connected with each end. To one wire was joined a thin plate of lac, coated on the ſide next the wire; and to the other a piece of moiſt leather covered with tin-foil. Theſe plates were rubbed together by means of inſulating handles. The plate of coated talc quickly took a charge.

The ſame plate of talc, and afterwards another plate not more than half as thick, was now made part of the excitatory arc, and ſometimes part of the animal arc. Sometimes plates of varniſh, incomparably thinner than either of theſe, were employed. But all Profeſſor Robiſon's attempts to produce an accumulation of galvanic energy in this way were fruitleſs. The ſecond form of the electrical experiment was adopted, as having a ſomewhat greater reſemblance to the ſuppoſed procedure of galvaniſm; but the well-informed electrician will eaſily perceive,

perceive, that the firſt form is far more delicate and deciſive.

The internal procedure in the electric and galvanic convulſions is therefore ſo different, nay, oppoſite, that we cannot bring ourſelves to think that the appearances are operations of the ſame agent (H).

We have now gone over all the points of reſemblance which, in Dr Valli's opinion, conſtitute the characters of the identity of galvaniſm and electricity. We think that, without going farther, we might ſafely reſt our aſſertion, that theſe two agents are perfectly diſtinct and unconnected with each other. But there are ſeveral other circumſtances which merit attention.

28 Farther conſiderations on electricity and galvaniſm.

No electrical phenomenon can take place between two bodies, unleſs theſe bodies be in oppoſite ſtates of electricity with regard to each other. Now, how are we to account for the accumulation of electricity in any body, or part of a body, ſurrounded on all hands by conducting ſubſtances? The experiments of Galvani ſucceed equally well, whether the ſubjects of them be inſulated or ſurrounded by conductors; whether performed in the drieſt air or under water (I); whether, by means of an electrical machine, we charge the animal and the metals till every part of them ſtrongly affect the electrometer, or whether we reverſe the experiment and electriſy them negatively, ſtill no change is produced in the force or frequency of the actions excited by the application of the metals. Is there any electrical experiment which could continue to give the ſame reſult in ſuch oppoſite circumſtances? or is there any poſſibility of accounting for it conſiſtently with the known laws of the electric fluid?

The writers on this ſubject who adopt the electric theory, inſtead of attempting to explain how the electric fluid can be condenſed in a body ſurrounded by conducting ſubſtances, have recourſe to the analogy of the gymnotus, torpedo, and other fiſhes of the ſame kind. Here, ſay they, we have in fact the electric fluid accumulated in ſuch a ſituation, and there is no reaſoning againſt facts. We anſwer, that theſe animals are all furniſhed with organs of a very peculiar ſtructure, which may poſſibly be fitted for the purpoſe of ſuch a condenſation. Beſides, we apprehend it has never been inconteſtibly proved that theſe ſingular animals derive their powers from the electric fluid. Without wiſhing to enter into this queſtion, which is foreign to our preſent ſubject, we may remark, that Mr Walſh diſcovered, that the ſhock of the torpedo would not paſs through a ſmall braſs chain; a circumſtance in which it differs remarkably both from electricity and from the influence diſcovered by Galvani.

It were worth while to try Profeſſor Robiſon's methods of accumulation in the examination of the convulſions occaſioned by the torpedo. The Profeſſor ſuſpects that the popular horror at the lamprey, and the accounts of cramps and pains produced by it, have their ſource in ſome ſimilar powers of that animal.

Dr Valli's reaſoning on this part of the ſubject is very curious. He takes it for granted that the gymnotus owes its influence to the electric fluid. Then, though the gymnotus gives ſhocks and emits ſparks, while the torpedo only gives ſhocks without emitting ſparks, he ſays it would be abſurd to aſſert that the torpedo derives its influence from a cauſe different from the gymnotus. Again, though the influence diſcovered by Galvani neither gives ſhocks nor emits ſparks, it would ſtill be abſurd to maintain that it is not the ſame as the electric fluid, and as the influence of the gymnotus and torpedo. To diſſent from any part of this very logical deduction, he declares would be contrary to the laws of philoſophiſing! *Riſum teneatis?*

Afraid, probably, that his readers might be tempted to offend againſt theſe new laws, he proceeds to ſtrengthen them by the analogy of animals and vegetables retaining an uniform temperature *in media*, warmer or colder than their own bodies; from which he argues that they may alſo have a power of accumulating electricity, and retaining it in a particular part, though their whole bodies are conductors. But the caſes are in no reſpect ſimilar. Neither animals nor vegetables accumulate caloric in any particular part of their bodies in preference to any other part. They have no power of *retaining* caloric in their bodies more ſtrongly than any other bodies do; for if they are placed in a medium colder than themſelves, they are continually imparting caloric to that medium. Neither is there the ſmalleſt proof, from any experiments yet publiſhed, that when placed in a medium warmer than themſelves, they do not continually abſorb caloric from it. The exiſtence of a frigorific power in animals appears to us exceedingly problematical; but if it were proved to exiſt, it would by no means demonſtrate that animals or vegetables have a faculty of declining to abſorb caloric from bodies warmer than themſelves. It is readily admitted, that animals and vegetables have a power, within certain limits, of preſerving their temperature higher than that of the ſurrounding medium; nor is there any thing ſurpriſing in this, as the caloric, which they are continually receiving by the decompoſition of oxygenous gas, is diſſipated ſlowly. But if we ſhould allow that animals have a ſimilar faculty of generating the electric fluid; from the nature of that fluid it muſt be continually communicated, not only to every part of the bodies of the animals themſelves, the whole of which are conductors, but to every conducting ſubſtance contiguous to them: and this muſt take place, not ſlowly, like the diſſipation of caloric, but inſtantaneouſly, ſo as to render any ſenſible accumulation impoſſible.

29 Difference in their mode of excitement,

Galvaniſm differs from electricity in nothing more remarkably than in the mode of its excitement and diſcharge.

(H) What if it were called *metallorgaſm*, which tranſlates exactly metallic irritation, or metallegerſiſm, from μεταλλον, and εγερσις *excitatio*.

(I) Dr Fowler mentions an exception to this. "When the ſeparated leg of a frog was held under water, and formed part of the circuit through which this influence had to paſs in order to excite another leg, it never contracted; although it did, and ſtrongly, when held above the ſurface." In this caſe it is plain, that the frog's leg had in fact formed no part of the circuit through which the influence paſſed; the influence had been tranſmitted by the water in which the leg was held.

charge. To produce the phenomena discovered by Galvani, no operation at all similar to the friction of an electric upon a conducting substance is necessary (I). The nerves and muscles have only to be laid bare, and a communication formed between them by means of the excitatory arc, when the contractions immediately ensue. In the case of electricity, a single discharge having restored the equilibrium, no farther effects can be produced till this has been again destroyed by some means capable of producing a condensation in one quarter, and a comparative rarefaction in another. The fact is very different with regard to galvanism; for with it the number of shocks which may be given appears to be infinite. Nay, they frequently become stronger in proportion as they have been longer continued: this influence differing extremely in this particular, too, from the electric fluid, which, besides being itself exhausted, never fails in a remarkable manner to exhaust the contractile power of the muscles.

30 And in the duration of their effects.

The permanence of the effects of galvanism is still more striking in the experiments upon the organ of taste. When the metals are applied to the tongue, the sensation produced is not sudden and transient; but so long as the metals are in contact with the tongue and with each other, so long does the taste continue; and, after some time, it becomes insufferably disagreeable. M. Volta, who adopts the electric theory with various modifications, sensible of the permanence of the effect, in his curious experiments abovementioned supposes, that a stream of electricity passes from the tin cup to the liquor, from this to the tongue of the person making the experiment, then through his body, and returns through the water upon his hands to the cup; and thus he supposes the fluid to move perpetually in a circle. It is surely unnecessary for us to observe, that the supposition of a stream of electricity, continually moving in a circle in this manner, is wholly inconsistent with the laws which appear in every case to regulate the motions of that fluid. The same observation applies to the manner in which he explains most of the other phenomena of galvanism.

The electric fluid cannot be put in motion but by destroying the equilibrium to which it perpetually tends; but whenever this is destroyed, all that is required to produce a discharge is, that a single conducting substance be placed between the two points in which it is unequally distributed. Here again there is a very wide distinction between this fluid and the influence discovered by Galvani. M. Volta divides all conductors of galvanism into two classes; 1st, Dry conductors, comprehending metals, pyrites, some other minerals, and charcoal; and, 2d, Moist conductors. He asserts, that it is absolutely necessary, in order to the production of the phenomena, that two conductors of the first class touch each other immediately on one hand, while at their other extremities they touch conductors of the second class. Whether this be admitted or not, we have already stated our opinion that the action of two different substances is absolutely necessary in order to excite contractions: and although it is contended by some writers that a single piece of metal has sometimes been found sufficient, yet even they must allow that, in by far the greater number of cases, it has been found necessary to make use of two metals, and that the effect is even heightened in general by employing three. In the whole science of electricity, we do not know a single fact which bears the slightest analogy to this. Never in a single instance has it been found, that the effects of a Leyden phial have been increased by using a conductor formed of two or more metals in procuring the discharge.

31 Some men non-conductors of galvanism.

Before leaving the subject of conductors, we may take notice of a very curious and important fact mentioned by Dr Valli. "Amongst men," says he, "there are some individuals who are good conductors, others who are less so; and some again who appear to be almost non-conductors. I was one day carrying on, with three of my friends, some experiments upon frogs. A frog was put in water, and we each by turn essayed its power. Two of us excited strong convulsions, the third only feeble ones, and the fourth none at all. This experiment was repeated frequently with the same result. This is not the only example I could adduce of the reality of this fact, but I do not think it necessary to dwell any longer upon it." We have met with one individual who is not sensible of any peculiar sensation when the metals are applied to his tongue. This seems in some measure to corroborate Dr Valli's observation. It is apprehended, however, that all men are equally good conductors of electricity.

There is still another very marked distinction between the effects of galvanism and electricity. No shock at all resembling that produced by the electric fluid has ever been felt by any person whose body was made a part of the chain conducting the galvanic influence, while a very small quantity of the electric fluid is immediately felt (K). In Dr Robison's experiment with the plates of zinc and silver in the cheeks, there is no doubt a convulsive twitch distinctly felt in the gums; but, as we have already observed, the sensation thus produced

---

(I) It is true, as we have noticed above, that galvanic energy is sometimes communicated to a conducting substance by rubbing it upon some other substance; but this has no resemblance to the excitement of electricity by friction. The galvanic energy is communicated in this case to a *conducting* substance, and it succeeds as readily when both the bodies are of this class as when one of them is an idio-electric. But no electric phenomenon has ever been produced by the friction of two conducting bodies upon each other; one of them must be an idio-electric, and it is in this one that the excitement takes place.

(K) There is an exception to this rule which ought to be taken notice of. M. Cotugno informs us, that when he was one day employed in dissecting a live mouse, he received a sensible shock from the animal. But as neither he nor any other person has ever been similarly affected in any other instance, it seems pretty certain that he was deceived into the belief of a shock from the sensation produced by the struggles of the animal he dissected.

produced is quite different from that which is felt from an electric shock (L).

There is an experiment related by Dr Valli, which seems to shew that nothing like an electric shock is felt, even when this influence is transmitted through a nerve so as to excite convulsions. Having laid bare the nerves of a fowl's wing, without cutting them, and without killing the fowl, upon applying the metals very smart movements were produced, but the animal remained perfectly tranquil. Nor was this owing to the fowl being in a state of insensibility; for when the nerves were pricked or irritated it screamed violently. But all animals shew signs of great uneasiness from an electric shock.

In general, it must be confessed, that animals under experiments of this kind seem restless and uneasy. The great distinction of which we speak at present, consists in this, that the electric fluid produces a shock and uneasy sensation when any part of the body is introduced into the conducting chain; while the influence discovered by Galvani, on the contrary, when merely transmitted through the body in this manner, gives no shock, nor any sensation whatever, insomuch that we are not sensible of its passage. If this influence be made to act directly on a nerve, there is, no doubt, some kind of irritation produced, as appears from the effect of the metals upon the tongue, the eye, and other nervous parts: but still this action bears no analogy to that of the electric fluid; as the application of the metals to the organs of sense, produces in each organ the peculiar sensation for which it is constructed, as taste in the tongue, light in the eye, &c. so when nerves intended merely for muscular motion are subjected to the action of galvanism, the effect produced is motion in the muscles on which they are distributed.

If this view of the matter be just, it will explain why no shock is felt when the human body is made a part of the conducting chain. In that case the influence does not, in all probability, act directly upon any nerve; and we see that this influence possesses no power, like the electric fluid, of producing a convulsive shock, when merely passed through any part of the body; but it has this peculiar property, when passed directly through a nerve, it excites that nerve to perform the function for which it was intended by nature. To this it will no doubt be objected, that contractions may be excited in different parts of a frog without any division being made in its skin; and here it may be supposed that the influence is not made to pass directly through a nerve. But it ought to be recollected that the skin of these animals is abundantly supplied with nerves, whose trunks communicate at different places with those which supply the muscles; and that the contractions are always strong and easily excited, in proportion as they are applied near to the course of any of the nerves which go to the muscles. But though we had no doubt that the influence might be transmitted through the bodies of these animals, as well as through the human body, without any contractions being produced, we have thought it worth while to ascertain the fact by the following experiment.

A frog was prepared in the usual manner by coating its sciatic nerve with tinfoil, and laying the leg upon a plate of zinc. Another frog, in a very vigorous state had its fore legs and chest attached to a rod of silver, and its posterior extremities to a rod of zinc. The silver rod was applied to the tinfoil and nerve of the prepared frog, and the zinc rod to the plate of zinc upon which the leg was laid. Immediately very strong contractions took place in the leg; but no motion, nor the slightest mark of uneasiness, appeared in the other frog, through the body of which the influence must have passed. It is necessary in this experiment to dry the body of the frog which is to serve as a conductor very carefully, otherwise the influence might be transmitted by the water upon its surface without passing through its body.

There is an experiment mentioned by Dr Fowler, which shews a striking difference between electricity and galvanism. It was instituted with a view to ascertain the effects of the latter upon the blood vessels. The Doctor relates it as follows: "Having laid bare and separated from surrounding parts and from each other, the crural artery and nerve in the thigh of a full grown frog, I cut out the whole of the nerve between the pelvis and the knee: I then insinuated beneath the artery a thin plate of sealing-wax, spread upon paper, and broad enough to keep a large portion of the artery completely apart from the rest of the thigh. The blood still continued to flow through the whole course of the artery in an undiminished stream. The artery, thus partially insulated, was touched with silver and zinc, which were then brought into contact with each other; but no contraction whatever was produced in any muscle of the limb. This experiment was frequently repeated upon several different frogs, both in whom the nerve was, and in whom it was not divided. The result was uniformly the same. But vivid contractions were produced in the whole limb when an e-

lectric

(L) "No one (says M. Humboldt) can speak more decidedly on this subject than myself, having made several experiments on my own person, the seat of which, in some instances, was the socket of a tooth which I had caused to be extracted; in others, certain wounds which I made in my hand; and in others, the excoriations produced by four blistering plasters." The following is the result of these painful experiments. The galvanic irritation is always painful, and the more so in proportion as the irritated part is more injured, and the time of irritation more prolonged. The first strokes are felt but slightly; the five or six following are much more sensible, and even scarcely to be endured, until the irritated nerve becomes insensible from continued stimulus. The sensation does not at all resemble that which is caused by the electric commotion, and the electric bath; it is a peculiar kind of pain which is neither sharp, pungent, penetrating, nor by intermissions, like that which is caused by the electric fluid. We may distinguish a violent stroke, a regular pressure, accompanied by an unintermitting glow, which is incomparably more active when the wound is covered with a plate of silver and irritated by a rod of zinc, than when the plate of zinc is placed on the wound, and the silver pincers are used to establish the communication.

lectric spark, or even a full stream of the aura was passed into the artery."

Before taking leave of this branch of our subject, it may be proper to take notice of one fact, which may be thought to militate against the doctrine we have endeavoured to establish. It is said that a frog, exhausted and brought near to a charged electrophorus, has been found to resume its susceptibility. We think this fact may be accounted for without admitting any connection between galvanism and electricity, merely by supposing that the irritability of the muscles, which had been exhausted, was restored by the application of a moderate stimulus, (the electric fluid), of a kind different from those by which it had been exhausted. Such of our readers as are acquainted with the writings of modern physiologists on the subject of muscular irritability, will know that facts of this kind are very common. Thus it has been found by M. Humboldt, that the oxygenated muriatic acid has often restored irritability. To this explanation it will no doubt be objected, that the application of other stimuli, as alcohol and a solution of potash, instead of restoring, totally destroy the susceptibility of galvanism. Suspecting, that although these substances in a concentrated state destroy the susceptibility, yet that when sufficiently diluted, they might be found to have the opposite effect, we tried the following experiment, which confirmed our conjecture.

A frog, 57 hours after it had been decapitated, had ceased for above an hour to be capable of excitement by the application of the metals in any way that could be devised. A few drops of alcohol being diluted with about a tea-spoonful of water, the nerve and the muscles which had been laid bare, as well as the whole skin of the animal, were wet with it. Upon the application of an excitatory arc, composed of four pieces, gold, zinc, silver, and tinfoil, a few very slight contractions of the toes were distinctly observed. After this, no means that we could think of produced the smallest excitement. Alcohol was now applied in a more concentrated state, but without any effect. The same four pieces of metal which produced the contractions of the toes, had been used before the diluted alcohol was applied, but without effect. We have not tried the application of potash much diluted.

From what has been said, we think we are fully warranted in saying, that although some of the phænomena discovered by Galvani bear a striking resemblance to some of those produced by the electric fluid; yet there are others, and these not the least important, which differ so widely from any effects which have ever been seen to arise from that fluid, that they must derive their origin from some other cause. Our readers may probably think that we have dedicated too much time to this question; but as we conceive it to be the most important point which can be discussed on this subject, we thought it worth while to consider it at some length; and we were the more convinced of the necessity of doing so, from this consideration, that there are still some writers of high authority who maintain the hypothesis, that galvanism and electricity are the same.

32 The galvanic influence probably foreign from animals.

The next question that occurs to us with regard to the nature of galvanism is, whether or not it depends upon any law of animal life? To us it appears rather more probable, that the influence which incites the muscles of animals to contract in the experiments of Galvani, is something quite foreign to the animals themselves; as much so as the electric fluid of the Leyden phial is to the animal which receives a shock from it, in both cases the body of the animal acting as a mere conductor. Upon this question, however, we confess that we have neither facts nor arguments to adduce sufficient to warrant our drawing any certain conclusion. It will doubtless be asked, if this influence be something foreign to the bodies of animals, why do we never find it acting anywhere but in their bodies? why is it not, like the electric fluid, capable of being made evident to the senses by its effects upon inanimate matter? The only answer which we are in a condition to give to this question is, that it may very possibly be capable of producing important effects upon inanimate matter, nay, these effects may be the subject of our daily observation; but for want of our being sufficiently acquainted with galvanism to point out the relation between these effects and their cause, the effects themselves are either not explained at all, or ascribed perhaps to some other power, with which they have no connection. In like manner, the electric fluid has doubtless been producing most important effects from the beginning of time; but, prior to the discovery of that fluid, these were either not explained at all, or considered as originating from some cause which, in fact, had no share in their production.

The great difficulty is to obtain some test by which we may detect the galvanic influence when actually present in inanimate matter. Hitherto we have no such test; nor should we know that such an influence exists, but for the effects which it produces upon the bodies of animals through the medium of their nerves. If we had any means of ascertaining its existence, either in a separate state, or conjoined with inanimate matter, the science would make a rapid progress, as it would be easy to diversify experiments so as to discover its nature and effects. To detect it in a separate state is, in all probability, impossible; but that the zeal and ingenuity of philosophers will one day be able to discover some test of its presence in inanimate matter, there seems no reason to doubt.

We have made many experiments with a view to discover such a test, but hitherto without the smallest success. In the trials we have already made, our views have been chiefly confined to the discovery of some chemical effects of this influence upon inanimate matter. M. Volta and other writers, having considered the sensation produced by it upon the tongue as similar to that occasioned by acids, we were not without hopes that it would be found to resemble that class of substances in some of its other properties. We have therefore transmitted it through liquids tinged with the most delicate vegetable colours; but no change in these colours has been effected by the transmission of many galvanic shocks. We have also tried, in the same way, alkaline liquors, without any effect. We next dissolved in water different neutral salts, and other compound bodies, of which the parts are held together by the weakest affinities; but no change has been observed to be produced in them by the transmission of this influence. Our want of success, however, shall not deter us from continuing our efforts; we shall vary the nature of our experiments

in

in every way that ſhall occur to us as likely to be attended with advantage; and if we ſhould ultimately fail, we truſt that others will be more fortunate. Every new fact which is diſcovered upon the ſubject tends to facilitate this inveſtigation, by furniſhing us with new guides to direct the courſe of our experiments.

33
Dr Fowler heſitates on this point,

Dr Fowler is of opinion, that this influence, whatever it may be, is not derived from the metals alone, but that the animals at leaſt contribute to its production, as well as indicate its preſence; and he ſeems to have been led to adopt this theory chiefly from two conſiderations, neither of which appears to us to have much weight. They are the following: The neceſſity of a communication between the metals and the muſcles, as well as between the metals and the nerves; and the obſervation, that animals have a more complete controul over its effects than one would expect them to have over an influence wholly external to them. But the communication between the metals and the muſcles may be neceſſary to the contraction of the latter, tho' not to the production of galvaniſm; which, however, for want of any obvious effect, is not obſerved. That animals have ſome controul over the effects of galvaniſm upon themſelves, may be very true; but this circumſtance does not appear to us capable of proving any thing, as they have a controul over the effects of other ſtimuli in the ſame way. Thus, an animal of any reſolution can bear, without betraying any uneaſy ſenſation, a blow which, inflicted unexpectedly, would have produced a convulſive ſtart. The will does not in any degree controul the effects produced by galvaniſm upon our ſenſes of taſte, ſeeing, &c.; that is, the ſenſations are produced, though we may have reſolution not to betray them. But, ſays Dr Fowler, the will is not able to controul the effects of electricity, when the electricity is otherwiſe ſufficiently ſtrong to excite muſcles to contraction. This argument may tend to ſhew, that galvaniſm differs from electricity; but as it muſt be admitted, that we can reſiſt the contractions naturally produced by the application of other foreign ſtimuli, it by no means proves that animals have any power of preventing the excitement or tranſmiſſion of galvaniſm. Beſides, though we cannot prevent an involuntary contraction of our muſcles from taking place when an electric ſhock of conſiderable ſtrength is paſſed through them, yet any man may with his hand draw ſparks from the prime conductor of an electric machine without ſhrinking, though even theſe ſparks would, if he were off his guard, produce a convulſive ſtart.

34
We think without reaſon.

If the galvanic influence exiſted ready formed in the muſcles or nerves of animals, the only thing requiſite to the production of the contractions would be to make a communication between the nerves and muſcles, by means of any ſingle ſubſtance capable of conducting this influence; as water, for example: but the reverſe is known to be true. It may be ſaid, however, that, although there is no proof that any influence naturally reſides in the nerves or muſcles capable of producing the effects mentioned by M. Galvani, theſe ſubſtances may ſtill, by ſome power independent of the properties they poſſeſs in common with dead matter *contribute* to the excitement of the influence, which is ſo well known to exiſt in them after a certain application of metals. Upon this part of the ſubject, the obſervations of Dr Wells will be found to merit conſiderable attention.

"It is known (ſays that gentleman), that if a muſcle and its nerve be covered with two pieces of the ſame metal, no motion will take place upon connecting thoſe pieces by means of one or more different metals. After making this experiment one day, I accidentally applied the metal I had uſed as the connector, and which I ſtill held in one hand, to the coating of the muſcle only, while with the other hand I touched the ſimilar coating of the nerve, and was ſurpriſed to find that the muſcle was immediately thrown into contraction. Having produced motions in this way ſufficiently often to place the fact beyond doubt, I next began to conſider its relations to other facts formerly known. I very ſoon perceived, that the immediate exciting cauſe of theſe motions could not be derived from the action of the metals upon the muſcle and nerve to which they were applied; otherwiſe it muſt have been admitted, that my body, and a metal formed together a better conductor of the exciting influence than a metal alone; the contrary of which I had known, from many experiments, to be the caſe. The only ſource, therefore, to which it could poſſibly be referred, was the action of the metals upon my own body. It then occurred to me, that a proper opportunity now offered itſelf of determining whether animals contribute to the production of this influence by means of any other property than their moiſture. With this view, I employed various moiſt ſubſtances, in which there could be no ſuſpicion of life to conſtitute, with one or more metals, different from that of the coatings of the muſcle and nerve, a connecting medium between theſe coatings, and found that they produced the ſame effect as my body. A ſingle drop of water was even ſufficient for this purpoſe; though in general, the greater the quantity of the moiſture which was uſed, the more readily and powerfully were contractions of the muſcle excited. But if the mutual operation of metals and moiſture be fully adequate to the excitement of an influence capable of occaſioning muſcles to contract, it follows, as an immediate conſequence, that animals act by their moiſture alone in giving origin to the ſame influence in M. Galvani's experiments, unleſs we are to admit more cauſes of an effect than what are ſufficient for its production." We do not quote the above reaſoning as perfectly concluſive, for it by no means appears to us to be ſo; but it certainly gives ſome probability to the opinion, that galvaniſm is, as M. Volta ſuppoſes, the reſult of the action of two dry conductors, which touch each other immediately on one hand, while at their other extremities they touch conductors of what he calls the ſecond claſs, (that is, moiſture, for all the conductors of the ſecond claſs contain water), and that the bodies of animals act merely as moiſture.

One of M. Humboldt's experiments related above, appears to us to ſtrengthen the concluſion, that the influence diſcovered by Galvani is ſomething perfectly foreign to the bodies of animals. Can it be ſuppoſed that any ſubſtance which naturally reſides in our bodies, ſhould, in a few ſeconds after it is put in motion, convert the ſimple ſerous diſcharge of a bliſter into a dark coloured fluid, of a nature ſo acrid as to irritate and violently inflame the ſkin wherever it touches it? We do not ſay that this is impoſſible, for we are too little acquainted with the laws of ſecretion to ſay with certainty

tainty what may, or what may not, produce such a change; but we know no similar alteration produced *in a few seconds*, by a mere change of action in the vessels themselves.

35 The cause which produces the galvanic effects unknown.

We shall not undertake to determine the nature of the cause which produces such astonishing effects. We think it is certainly not the electric fluid, and probably something which resides or is formed in the excitatory arc, but we consider our knowledge of galvanism as still in its infancy, and our stock of facts as infinitely too small to admit of our forming a just theory on the subject. Fortunately, however, the discovery of Galvani has attracted so much the attention of philosophers in every part of Europe, that new facts may be expected to come to light every day; and we hope the time is not very distant, when these may be so classed, as to entitle the subject to be ranked among the sciences.

While this article was in the press, we were favoured by a friend with an account of some German dissertations on the subject, which we are obliged to insert in this irregular manner.

Mr Creve, surgeon in Wurtzburg, had an opportunity of observing the galvanic irritation on the leg of a boy, which had been amputated far above the knee in the hospital of that city. Immediately after the amputation, Mr Creve laid bare the crural nerve (kniekehlnerven) and surrounded it with a slip of tinfoil. He touched, at once the tinfoil and the nerve with a French crownpiece. In that instant the most violent convulsions took place in the leg both above and below the knee. The remainder of the thighbone bent with force toward the calf; the foot was more bent than extended. All these motions were made with much force and rapidity. None were produced when the tinfoil was taken away, or when a steel pincer was used in place of a piece of silver, or when the tin or silver was covered with blood: but they were renewed when these obstacles were removed. These phenomena continued till 38 minutes after the amputation, when the limb became cold.

Dr Christopher Heinrich Pfaff (*in Dissertatione de Electricitate Animali*, Stutgardt, 1793: see also Gren's *Journal der Physik*, T. viii. p. 196, &c.) has classed the phenomena in a very orderly and perspicuous manner; and the result of the numerous experiments made by himself and others corresponds very nearly with our inferences in the preceding pages.

I. *Phenomena of muscular contraction.*

The general form of his experiments is the same with that which we have placed at the beginning of this article; but the following varieties were observed:

The nerve being coated with tinfoil, it was always observed that the contractions were stronger when the silver first touched the muscle, and then the coating. If it touched the coating first, the effects were always, and very sensibly, weaker.

They were still stronger when the silver did not touch the muscle at all, but only the nerve and its coating.

When the contractions were weaker at the beginning, they also ceased sooner.

No contraction ensued from touching the coating only, or the nerve only, or the muscle only, with the silver.

Continuing the contact did not occasion any repetition of the contractions, except in some cases, where the silver was drawn along different parts of the coating, while its other end remained in contact with the nerve.

The contractions took place only in the muscles to which the nerve led.

Their strength and duration were greater when the surfaces of contact were greater, and when the two metals touched each other in points or sharp edges.

A ligature, with a silk thread below the coating (that is, between the coating and the muscle, or part of the nerve touched by the silver), prevented all contraction; but not if the ligature was between the coating and the brain. If the nerve was cut through below the coating, and the parts separated a quarter of an inch, no contraction followed by touching the coating and the nerve or muscle: but it took place, if the parts were brought into contact; or even if a piece of any other nerve was put between the parts.

If a considerable part of a bared nerve was insulated and coated, partly with tinfoil and partly with silver, contractions were produced in the muscle to which it led whenever the two metals were brought into contact.

If one crural nerve be coated with tin, and the other with silver, contractions are produced in both legs by bringing the metals into contact.

If the nerve be dry under the coating, or when the silver touches it, or in both places, we have no contractions; but they begin as soon as we moisten the nerve.

Dr Pfaff infers from these phenomena, that the nerve alone is subject to the irritation produced by the two metals.

If the prepared frog be immersed in water, so that the coating touches the water, contractions are produced by touching the coating above water with the silver, while another part of the silver touches the nerve, or the muscle, or even dips pretty deep in the water.

No such thing happens in oil; or, at best, the contractions are very slight.

Dr Pfaff could not produce contractions without employing two metals, or a metal and charcoal.

A very thin covering of muscular flesh on the nerve did not altogether prevent the contractions, and in many cases did not sensibly diminish them.

If a piece of silver be laid on the muscles of the breast or belly, and be brought into contact with the tin-coating on the lumbal region, only the muscles of the breast or belly are affected, but not those of the legs.

Dr Pfaff says, that the involuntary muscles are not affected by galvanism; and refers for convincing proofs to a dissertation by Dr Ludwig, shewing that the heart is not furnished with nerves, (*Scriptor. neurolog. minor. select.* vol. 2.).

II. *Irritation of the Organs of Sense.*

Here Dr Pfaff's dissertation contains nothing remarkable.

III.

III. *Conjectures as to the Cause.*

Dr Pfaff uses the same arguments that we have employed to refute the opinion of a similarity between the animal organs and the Leyden phial, and the opinion that electricity is the agent. He mentions the opinion of those who maintain that the agent is a fluid put into motion by means of its relation to the metals only, in their action on each other, and who consider the animal as merely serving as a conductor; and also serving, by its irritability, to give us the information of the presence of such a fluid, in the same manner as another kind of irritation, somewhat analogous to it, indicates the presence and agency of the electric fluid. It may therefore be called the Metallic Irritation; a term which will sufficiently distinguish it.

But Dr Pfaff seems rather to think that the agent resides in the animal, and that the metals are the conductors (See a dissertation, entitled, *Farther Contributions to the Knowledge of Animal Electricity*, in *Gren's Journal der Physik*, T. viii. p. 377). This fluid he conceives to be intimately blended with the *principle of life*; nay, perhaps, to be the same. He mentions a thought of Professor Kielmayer, "that it may resemble the magnetic fluid in its manner of acting, giving connection to the distant particles of a nerve, as we observe a magnet give an instantaneous connection to each of a parcel of iron filings; all of which it would arrange in a certain precise manner, if they were sufficiently moveable, by giving momentary polarity to each." This somewhat resembles Newton's hypothetical whim read to the Royal Society, describing what may be done by means of an æther (See *Birche's History of the Royal Society*).

But all this is vague conjecture, and merits little attention. This will be better bestowed on an observation of M. Humboldt of Jena, "that a bit of fresh morelle (the *Helvella mitra* of Linnæus) may be substituted for a bit of nerve in the animal arc in these experiments." This is the only vegetable substance yet discovered to have this property. If the nerve be laid on the morelle, we have only to touch the morelle with the zinc, and the muscular contractions immediately follow.

GALWAY, a township in the new county of Saratoga, in New-York. By the state census of 1796, it appears that 491 of its inhabitants are qualified to be electors.—*Morse.*

GAMBLE's *Station*, a fort about 12 miles from Knoxville, in Tennessee.—*ib.*

GAMMON, Point, anciently called Point Gilbert, by Gosnold, forms the eastern side of the harbor of Hyanis or Hyennes, in Barnstable co. Massachusetts. —*ib.*

GARAZU, a town in Brazil, and province of Pernambuco, 25 miles N. of Olinda.—*ib.*

GARDECAUT, or Guard du Cord, in a watch, is that which stops the fusee when wound up, and for that end is driven up by the spring. Some call it Guard-cock; others Guard du Gut.

GARDEN (Francis), better known to the public by the title of *Lord Gardenstone*, was born at Edinburgh June 24th, in the year 1721. His father was Alexander Garden of Troup; an opulent landholder in Aberdeenshire; his mother was Jane, daughter of Sir Francis Grant of Cullen, S.C.I.

After passing through the usual course of liberal education at the school and the university, he betook himself to the study of law for his profession. In the year 1744 he was admitted a member of the Faculty of Advocates, and called to the Scottish bar.

In his practice as an advocate he soon began to be distinguished, by a strong, native rectitude of understanding; by that vivacity of apprehension and imagination, which is commonly denominated *Genius*; by manly candour in argument, often more persuasive than subtlety and sophistical artifice; by powers which, with diligence, might easily attain to the highest eminence of the profession. But the same strength, openness, and ardour of mind, which distinguished him so advantageously among the pleaders at the bar, tended to give him a fondness for the gay enjoyments of convivial intercourse, which was unfavourable to his progress in juridical erudition. Shining in the social and convivial circle, he became less solicitously ambitious than he might otherwise have been, of the character of an eloquent advocate, or of a profound and learned lawyer. The vivacity of his genius was averse from austere and plodding study, while it was captivated by the fascinations of polite learning, and of the fine arts. Nor did he always escape those excesses in the pursuit of pleasure into which the temptations of opening life are apt, occasionally, to seduce the most liberal and ingenuous youth. But his cheerful conviviality, his wit, humour, taste, good-nature, and benevolence of heart, rendered him the delight of all his acquaintance. He became his Majesty's Solicitor July 3d, 1764.

At length the worth of his character, and his abilities as a lawyer, recommended him to the office of a Judge in the Courts of Session and Justiciary, the supreme judicatures, civil and criminal, for Scotland. His place in the Court of Session he continued to occupy till his death; but had, some years before, resigned the office of a Commissioner of Justiciary, and in recompence got a pension of 200l. per annum. Clear discernment, strong good sense, conscientious honesty, and amiable benevolence, remarkably distinguished all his opinions and conduct as a judge.

We not unfrequently see the gay young men of the present age, to turn, as they advance towards middle life, from the headlong pursuit of pleasure to a sordid and contracted selfishness, which excludes even those few good qualities that seemed to accompany their first thoughtless days. Their life is divided between sensuality and that anxious *inhumane* avarice and ambition whose ultimate object is, to provide gratifications to sensuality and pride. The kindling light of rectitude, and the first sparks of generous humanity, are extinguished in their hearts, as soon as those ebullitions of youthful passion and inexperience are over, by which

Garden.

the useful efficiency of their early good qualities was prevented. Hardly have they become tolerably well acquainted with mankind, when the milk of human kindness is turned into gall and venom in their hearts.

It was far otherwise with Lord Gardenstone. As he advanced in years, humanity, taste, public spirit, became still more and more eminently the predominant principles in his mind.—He pitied the condition of the peasantry, depressed rather by their ignorance of the most skilful modes of labour, and by their remoteness from the sphere of improvement, than by any tyranny or extortion of their landlords. He admired, protected, and cultivated the polite arts. He was the ardent votary of political liberty, and friendly to every thing that promised a feasible amelioration of public economy, and the principles of government.

In the year 1762 he purchased the estate of Johnston, in the county of Kincardine. Within a few years after he began to attempt a plan of the most liberal improvement of the value of this estate, by an extension of the village of Laurencekirk, adjoining. He offered leases of small farms, and of ground for building upon, which were to last for the term of one hundred years; and of which the conditions were extremely inviting to the labourers and tradesmen of the surrounding country. These offers were eagerly listened to. More desirous to make the attempt beneficial to the country than to derive profit from it to himself, he was induced, within a few years, to reduce his ground-rents to one-half of the original rate.—Weavers, joiners, shoe-makers, and other artisans in a considerable number, resorted to settle in the rising village. His Lordship's earnestness for the success of his project, and to promote the prosperity of the good people whom he had received under his protection, led him to engage in several undertakings by the failure of which; he incurred considerable losses. Projects of a print-field, and of manufactures of linen and of stockings, attempted with sanguine hopes in the new village, and chiefly at his Lordship's risk and expence, misgave in such a manner as might well have finally disgusted a man of less steady and ardent philanthropy with every such engagement. But the village still continued to advance. It grew up under his Lordship's eye, and was the favourite object of his care. In the year 1779, he procured it to be erected into a burgh of barony; having a magistracy, an annual fair, and a weekly market. He provided in it a good inn for the reception of travellers; and with an uncommon attention to the entertainment of the guests who might resort to it, furnished this inn with a library of books for their amusement. He invited an artist for drawing, from the continent, to settle at Laurencekirk. He had the pleasure of seeing a considerable linen manufacture at length fixed in it. A bleachfield was also established as a natural counterpart to the linen-manufacture. Before his Lordship's death, he saw his plan of improving the condition of the labourers, by the formation of a new village at Laurencekirk, crowned with success beyond his most sanguine hopes. He has acknowledged, with an amiable frankness, in a memoir concerning this village, "That he had tried, in some measure, a variety of the pleasures which mankind pursue; but never relished any so much as the pleasure arising from the progress of this village."

Garden.

In the year 1785, upon the death of his elder brother Alexander Garden of Troup M. P. for Aberdeenshire, Lord Gardenstone succeeded to the possession of the family estates, which were very considerable. Until this time his Lordship's income had never been more than adequate to the liberal expence into which his rank and the generosity of his nature, unavoidably led him. But the addition of a fortune of about three thousand pounds a-year to his former revenue, gave him the power of performing many acts of beneficence with which he could not before gratify his good heart. It was happy, likewise, that his succession to this ample income, at a period when the vigour of his constitution was rapidly yielding to the infirmities of old age, enabled him to seek relief, by a partial cessation from business, by travel, and by other means, which could not have been easily compatible with the previous state of his fortune.

In the month of Sept. 1786, he set out from London for Dover, and passed over into France. After visiting Paris, he proceeded to Provence, and spent the winter months in the genial climate of Hieres. In the spring of 1787 he returned northwards, visiting Geneva, Switzerland, the Netherlands, and the Dutch provinces, and passing through Germany into Italy. With a fond curiosity, attentive alike to the wonders of nature, to the noble monuments of the arts, and to the awful remains of ancient grandeur, with which Italy abounds, he visited all its great cities, and surveyed almost every remarkable and famous scene that it exhibits.

His first object, in these travels, was to obtain the restoration of his declining health by the influence of a milder climate, by gentle, continued, and varied exercise; by that pleasing exhilaration of the temper and spirits which is the best medicine to health, and is most successfully produced by frequent change of place, and of the objects of attention. But the curiosities of nature and art, in those countries through which he travelled, could not fail to attract, in a powerful manner, the curiosity of a mind cultivated and ingenious as his. He, whose breast glowed with the most ardent philanthropy, could not view the varied works and manners of a diversity of nations of his fellow men, without being deeply interested by all those circumstances which might appear to mark their fortunes as happy or wretched. He eagerly collected specimens of the spars, the shells, the strata of rocks, and the veins of metals, in the several countries through which he passed. He amassed also cameos, medals, and paintings. He enquired into science, literature, and local institutions. He wrote down his observations, from time to time; not indeed with the minute care of a pedant, or the ostentatious labour of a man travelling with a design to publish an account of his travels; but simply to aid memory and imagination in the future remembrance of objects useful or agreeable.

After an absence of about three years, he returned to his native country. The last years were spent in the discharge of the duties of his office as a judge; in social intercourse with his friends, among whom was the venerable Lord Monboddo, and others of the most respectable characters which that country has to boast of; in the performance of a thousand generous offices of benevolence and humanity; in cherishing those fine arts, of which he was an eminent admirer and judge;

and

Garden.

and above all, in promoting the comfort, and encouraging the induſtry of his dependants, and in lending his aid to every rational attempt at the improvement of public economy and public virtue.

St Bernard's Well, in the neighbourhood of Edinburgh, had been, long ſince, diſtinguiſhed for the medicinal virtues of its waters. But various circumſtances had alſo concurred of late to throw it into neglect. Yet its waters being ſtrongly mineralized by a ſulphurated hydrogenous gas, were, by this means, unqueſtionably qualified to operate, with highly beneficial effects, in the cure of various diſeaſes. The qualities of this mineral water falling under Lord Gardenſtone's notice, he was induced to purchaſe the property of the well, to direct it to be cleared from ſurrounding obſtacles, which contaminated the virtues of the water, or made it inacceſſible; to erect a beautiful and commodious edifice over it; and to appoint proper perſons to diſtribute the water, for a very trivial compenſation, to the public. The well lies at a diſtance from Edinburgh, which is very convenient for a ſummer morning's walk. Within the few years which have paſſed ſince Lord Gardenſtone's benevolent care brought it into notice, it has attracted many of the inhabitants of that city to viſit in the mornings of ſpring and ſummer. And, undoubtedly, the agreeable exerciſe to which they have thus been allured, and the ſalutary effects of the water, have contributed, in no mean degree, to diſpel diſeaſe, and to confirm or re-eſtabliſh health. Such monuments are worthy to preſerve the memory of a patriotic and a good man!

As an amuſement for the laſt two or three years of his life, when his increaſing infirmities precluded him from more active exerciſe, and from mingling ſo frequently in the ſociety of his friends as was agreeable to his ſocial and convivial temper, he bethought himſelf of reviſing ſome of the *jeux d'eſprit*, and light fugitive pieces, in which he had indulged the gaity of his fancy in his earlier days; and a ſmall volume of poems was publiſhed, in which the beſt pieces are, upon good authority, aſcribed to Lord Gardenſtone. He reviſed alſo the memorandums which he had made upon his travels, and permitted them to be ſent to preſs. The two former volumes were publiſhed one after another while his Lordſhip was yet alive; the third after his death. They met with a very favourable reception in the world, and were honoured with the high approbation of the moſt reſpectable writers of periodical criticiſm. They convey much agreeable information, and beſpeak an elegant, enlightened and amiable mind. The laſt volume is filled chiefly with memorandums of his Lordſhip's travels in Italy; and contains many intereſting criticiſms upon ſome of the nobleſt productions of the fine arts of painting and ſculpture.

His Lordſhip's health had long been declining; and he died a bachelor on the 22d of July 1793, lamented by his relations and friends, by his tenants and humble dependants, and by all true patriots and good men to whom his merits and virtues were known.

Such is the account of Lord Gardenſtone's life, which was prefixed to the third volume of his travelling memorandums; and though it was no doubt an effuſion of fond friendſhip, we believe that the praiſe which it beſtows on his Lordſhip is not much exaggerated. In the latter years of his life, it muſt indeed be confeſſed, that he contracted intimacies with men unworthy of his regard; and that his attachment to liberty made him form expectations from the French revolution, which even the events which he ſaw ought to have repreſſed. But his mind was by that time weakened by diſeaſe; and it would be very unjuſt to balance the imprudencies of one or two years againſt the meritorious actions of a whole life. Beſides his travelling memorandums and his poems, his Lordſhip publiſhed *a Letter to the Inhabitants of Laurencekirk*, the moſt valuable, in our opinion, of all his publications; for it contains perhaps the moſt ſalutary advices which were ever offered to the inhabitants of a manufacturing town, for the regulation of their conduct towards each other. That the people of Laurencekirk have followed theſe advices, it would give us pleaſure to learn on good authority.

Gardner || Gaſpee.

GARDNER, a townſhip in Worceſter co. Maſſachuſetts, incorporated in 1785. It contains about 14,000 acres, well watered, chiefly by Otter river. The road from Connecticut river, through Peterſham, Gerry, and Templeton on to Boſton, paſſes through it. It contains 531 inhabitants, and is 26 miles N. by W. of Worceſter, and 60 N. W. of Boſton.—*Morſe.*

GARDNER'*s Iſland*, or *Iſle of Wight*, lies at the E. end of Long-Iſland, in New-York ſtate, ſheltered within Oyſter Pond and Montauk points; 10 miles N. W. of the latter, and as far S. W. of Plumb Iſland. It contains about 3000 acres of fertile land, the property of one perſon, and yields excellent graſs, wheat and corn. Fine ſheep and cattle are raiſed on it. It is annexed to Eaſt Hampton, and lies 40 miles ſouth-weſterly of Newport, Rhode Iſland.—*ib.*

GAS. See that article, *Encycl.* and CHEMISTRY—*Index* in this *Supplement*. We have introduced the word here, to notice ſome experiments made by Profeſſor Jacquin of Vienna, at the deſire of Dr Chladni, on the different gaſes as the vehicle of ſounds. A glaſs bell was furniſhed with a metallic ſtopper cemented to a neck at the top: and in the bore of this cock, within the glaſs, a ſmall flute or pewter (etain) about ſix inches in length was fixed. The glaſs being then placed on the ſhelf of the pneumatic veſſel, and filled with any particular kind of gas, a bladder alſo filled with the ſame gas, and provided with a cock, was adapted to the external aperture of the cock belonging to the bell-glaſs. In this diſpoſition of the apparatus, the flute was made to ſound by gently preſſing the bladder. Comparative experiments were made with atmoſpheric air, oxygen, hydrogen, carbonic acid, and nitrous gas. The intenſity of the ſound did not vary; but when compared with that produced by atmoſpheric air, the oxygen gas gave a ſound half a tone lower; azotic gas, prepared by different methods conſtantly gave a ſound half a tone lower; hydrogen gas gave nine or eleven tones higher; carbonic acid gas gave one-third lower, and nitrous gas alſo very nearly a third lower. A mixture of oxygen gas and azote, in the proportions of the atmoſpheric air, afforded the tone of this laſt: that is to ſay, it was half a tone higher than each of the component parts alone. When the two gaſes were not uniformly mixed, the ſound was abominably harſh. Chladni intends to give a fuller account of theſe intereſting experiments. *Journal de Phyſique*, Vol. IV. N. S. p. 57.

GASPEE, or *Nanquit Point*, 7 miles S. of Providence

Gaspesia || Geneva.

dence (Rhode Island) projecting from the western shore of Providence river, remarkable as being the place where the British armed schooner, called the Gaspee, was burnt, June 10, 1772, by about 60 men from Providence, painted like Narraganset Indians. For the cause of this transaction, see Gordon's Hist. of the Amer. Rev. vol. I. p. 311.—*Morse.*

GASPESIA, a tract of country on the S. side of the mouth of St Lawrence river, and on the N. side of Chaleurs bay, in Lower Canada. Its E. extremity is Cape Rosiers. The Indians called Gaspesians inhabit here.—*ib.*

GATES *Co.* in Edenton eastern district, N. Carolina, is bounded N. by the state of Virginia, S. by Chowan co. It contains 5392 inhabitants, including 2219 slaves. Chief town, Hertford.—*ib.*

GAY *Head*, is a kind of peninsula on Martha's Vineyard, between 3 and 4 miles in length and 2 in breadth, and almost separated from the other part of the island by a large pond. The Indians inhabiting this part, when lately numbered, amounted to 203. The soil is good, and only requires cultivation to produce most vegetables in perfection. There are evident marks of there having been volcanoes formerly on this peninsula. The marks of 4 or 5 craters are plainly to be seen. The most southerly and probably the most ancient, as it is grown over with grass, now called the Devil's Den, is at least 20 rods over at the top, 14½ at the bottom, and full 130 feet at the sides, except that which is next the sea, where it is open. A man now alive relates that his mother could remember when it was common to see a light upon Gay Head in the night time. Others say, their ancestors have told them, that the whalemen used to guide themselves in the night by the lights that were seen upon Gay Head. The sea has made such encroachments here, that, within 30 years, it has swept off 15 or 20 rods. The extremity of Gay Head is the S. W. point of the Vineyard. N. lat. 41. 20. W. long. from Greenwich 70. 50.—*ib.*

GAZONS, in fortification, turfs, or pieces of fresh earth covered with grass, cut in form of a wedge, about a foot long, and half a foot thick, to line or face the outside of works made of earth, to keep them up, and prevent their mouldering.

GENESSEE *Country*, a large tract of land in the state of New-York, bounded N. and N. W. by lake Ontario, S. by Pennsylvania, E. by the western part of the military townships, in Onondago co. and W. by lake Erie and Niagara river. It is a rich tract of country, and well watered by lakes and rivers; one of the latter, Genessee river, gives name to this tract. It is generally flat, the rivers sluggish, the soil moist, and the lakes numerous.—*Morse.*

GENEVA, a lake in Upper Canada, which forms the W. extremity of lake Ontario; to which it is joined by a short and narrow strait.—*ib.*

GENEVA, a post town in Onondago co. New-York, on the great road from Albany to Niagara, situated on the bank of the N. W. corner of Seneca lake, about 74 miles W. of Oneida castle, and 92 W. of Whitestown. The Friends settlement lies about 18 miles below this. Here were 20 log-houses, and a few other buildings several years ago, which have much increased since.—*ib.*

Genevieve || George's.

GENEVIEVE, ST or *Missire*, a village in Louisiana, on the western bank of the Mississippi, nearly opposite to the village of Kaskaskias, 12 miles southerly of Fort Chartres. It contained about 20 years ago, upwards of 100 houses, and 460 inhabitants, besides negroes. —*ib.*

GEOCENTRIC PLACE of a planet, is the place where it appears to us from the earth; or it is a point in the ecliptic, to which a planet, seen from the earth, is referred.

GEOCENTRIC *Latitude* of a planet, is its latitude as seen from the earth, or the inclination of a line connecting the planet and the earth to the plane of the earth's (or true) ecliptic: Or it is the angle which the said line (connecting the planet and the earth) makes with a line drawn to meet a perpendicular let fall from the planet to the plane of the ecliptic.

GEOCENTRIC *Longitude* of a planet, is the distance measured on the ecliptic, in the order of the signs, between the geocentric place and the first point of Aries.

GEOMETRICAL METHOD OF THE ANCIENTS. The ancients established the higher parts of their geometry on the same principles as the elements of that science, by demonstrations of the same kind: and they were careful not to suppose any thing done, till by a previous problem they had shewn that it could be done by actually performing it. Much less did they suppose any thing to be done that cannot be conceived; such as the line or series to be actually continued to infinity, or a magnitude diminished till it become infinitely less than what it is. The elements into which they resolved magnitudes were finite, and such as might be conceived to be real. Unbounded liberties have of late been introduced; by which geometry, which ought to be perfectly clear, is filled with mysteries.

GEOMETRICAL *Solution* of a problem, is when the problem is directly resolved according to the strict rules and principles of geometry, and by lines that are truly geometrical. This expression is used in contradistinction to an arithmetical, or a mechanical, or instrumental solution, the problem being resolved only by a ruler and compasses.

The same term is likewise used in opposition to all indirect and inadequate kinds of solutions, as by approximation, infinite series, &c. So we have no geometrical way of finding the quadrature of the circle, the duplicature of the cube, or two mean proportionals, though there are mechanical ways, and others, by infinite series, &c.

GEORGE'S, ST a cape and islands nearly opposite to the river Apalachicola, on the coast of E. Florida. Cape St George's lies about 6 leagues to the eastward of Cape Blaize, being an elbow of the largest of St George's islands, in N. lat. 29 38. There is a large shoal running out from it a considerable way, but how far has not yet been ascertained. The coast between it and Cape Blaize, forms a kind of hollow bay, with deep soundings and a soft bottom. There are two islands to the N. W. of St George's Cape; that nearest to it is small, and remarkable for a clump of straggling trees on the middle of it; the other is pretty large, and of a triangular form, and reaches within 3 leagues of Cape Blaize, having a passage at each end of it for small craft into the bay, between these islands and

George ‖ George's. and the river Apalachicola; but this bay is full of shoals and oyster-banks, and not above two or three feet water at most, in any of the branches of that river.—*Morse.*

George, Fort, was situated on Point Comfort, at the mouth of James river, and 5 miles N. E. of Craney island, at the mouth of Elizabeth river, in Virginia.—*ib.*

George, Fort King, an ancient fort in Georgia, which stood 5 miles N. E. of the town of Darien, in Liberty co. situated at the head of a creek which flows into the ocean opposite Sapelo island. It is now in ruins.—*ib.*

George, Lake, in East Florida, is a dilatation of the river St Juan, or St John, and called also Great Lake. It is about 15 miles wide, and generally about 15 or 20 feet deep, excepting at the entrance of the river, where lies a bar, which carries 8 or 9 feet water. The lake is beautified with two or three fertile islands. The largest is about 2 miles broad, and commands a most delightful and extensive prospect of the waters, islands, E. and W. shores of the lake, the capes, the bay and mount Royal; and to the S. the view is very extensive. Here are evident marks of a large town of the aborigines, and the island appears to have been once the chosen residence of an Indian prince. On the scite of this ancient town stands a very pompous Indian mount, or conical pyramid of earth, from which runs in a straight line, a grand avenue or Indian highway, through a magnificent grove of magnolias, live oaks, palms and orange trees, terminating at the verge of a large, green, level savanna. From fragments dug up it appears to have been a thickly inhabited town.—*ib.*

George, Lake, lies to the southward of lake Champlain, and its waters lie about 100 feet higher. The portage between the two lakes is a mile and a half; but with a small expense might be reduced to 60 yards; and with one or two locks might be made navigable through, for batteaux. It is a most clear, beautiful collection of water; 36 miles long, and from 1 to 7 wide. It embosoms more than 200 islands, some say 365; very few of which are any thing more than barren rocks, covered with heath, and a few cedar, spruce and hemlock trees, and shrubs, and abundance of rattle-snakes. On each side it is skirted by prodigious mountains; from which large quantities of red cedar are annually carried to New-York for ship-timber. The lake is full of fishes, and some of the best kind, as the black or Oswego bass, also large speckled trouts. It was called lake Sacrament by the French, who, in former times, were at the pains to procure this water for sacramental uses in all their churches in Canada: hence probably it derived its name. The remains of Fort George stand at the S. end of the lake, about 14 miles N. by W. of Fort Edward, on Hudson river. The famous fort of Ticonderoga, which stood on the N. side of the outlet of the lake, where it discharges its waters into lake Champlain, is now in ruins.—*ib.*

Georges, St an island and parish belonging to the Bermuda isles, in the West-Indies. N. lat. 32. 45. W. long. 63. 30.—*ib.*

George's St a large and deep bay on the W. side of Newfoundland island. N. lat. 48 12.—*ib.*

George's Bank, St a fishing bank in the Atlantic ocean, E. of Cape Cod, in Massachusetts. It extends from N. to S. between 41. 15. and 42. 22. N. lat. and between 67. 50. and 68. 40. W. long.—*ib.* George's.

George's Key, St was one of the principal British settlements in the bay of Honduras. It was taken by the Spaniards during the American war, but retaken by the British soon after.

The British settlements on the Mosquito shore, and in the bay of Honduras, were surrendered to the crown of Spain, at the Spanish convention, signed at London, the 14th of July, 1786.—*ib.*

George's River, St in St Mary's co. Maryland, is a very broad but short creek, whose mouth lies between Piney Point and St Mary's river, on the N. bank of the Potowmack, opposite the island of the same name.—*ib.*

George's River, St in Lincoln co. district of Maine, or rather an arm of the sea, lies about 2 leagues S. W. of Penobscot bay. Four leagues from the mouth of this river stands Thomaston. This river is navigable for brigs and ships of a large burden up to the narrows; and from thence about 4 miles higher, to nearly the head of the tide, for sloops and schooners of 80 or 90 tons. It is about half a league wide up to the narrows. Of late several considerable vessels have been built in this river, which are employed in coasting, and sometimes in foreign voyages. There are now owned in this river, though it does not in all exceed 4 leagues in length, 1 brig, 2 topsail schooners, and 9 sloops: In all about 1100 tons. The navigation, however, is generally interrupted in winter, when not only the streams through the country, but the salt water rivers are locked up until spring. Fish abound here, of almost all kinds, in their season; and even lobsters, oysters, clams, and other delicacies of the aqueous kind, are plenty in this river.—*ib.*

George's, St a village nearly in the centre of Newcastle co. Delaware, on a creek of its own name, which falls into Delaware river, 4 miles below, a little above Reedy Island. It is 17 miles S. by W. of Wilmington, and 45 S. W. of Philadelphia.—*ib.*

Georges, St the capital of the island of Grenada, in the West-Indies; formerly called Fort Royale, which name the fort still retains. It is situated on a spacious bay, on the W. or lee-side of the island, not far from the S. end, and possesses one of the safest and most commodious harbors in the British W. Indies, which has lately been fortified at a very great expense, and declared a free port. This town was destroyed by a dreadful fire in 1771, and on November 1, 1775, it met with the like misfortune; and the loss was valued at £.500,000 The town now makes a very handsome appearance, has a spacious square or parade; the houses are built of brick, and tiled or slated; some few are built of stone, excepting the warehouses and dwelling-houses round the harbor, which are mostly wooden buildings. These are in a great measure separated from the town by a very steep and rocky hill, the houses on which, with the trees which serve for shade, have a romantic appearance. The town is computed to contain about 2000 inhabitants, many of whom are wealthy merchants. This was its situation before the insurrection of the negroes; of its present state we have not authentic information.—*ib.*

GEORGE-

GEORGETOWN, the chief town of Suffex co. Delaware, is fituated 16 miles W. S. W. of Lewiftown, and 103 S. of Philadelphia. It contains about 30 houfes and has lately been made the feat of the county courts.—*ib.*

Georgetown, a poft town in Maryland, fituated in Kent co. on the E. fide of Chefapeak bay, of about 30 houfes. It is 9 miles from the mouth of the river Saffafras, being feated on the S. fide oppofite to Frederic, 60 N. E. of Chefter, and 65 S. W. of Philadelphia.—*ib.*

Georgetown, a village of Fayette co. Pennfylvania, fituated on the S. E. fide of Monongahela river, at the mouth of George's creek. Here a number of boats are annually built for the trade and emigration to the weftern country. It lies 16 miles S. W. of Union.—*ib.*

Georgetown, a poft town and port of entry, in Montgomery co. Maryland, and in the territory of Columbia. It is pleafantly fituated on a number of fmall hills, upon the northern bank of Potowmack river; bounded eaftward by Rock creek, which feparates it from Wafhington city, and lies 4 miles from the capitol, and 8 N. of Alexandria. It contains about 230 houfes, feveral of which are elegant and commodious. The Roman Catholics have eftablifhed a college here, for the promotion of general literature, which is at prefent in a very flourifhing ftate. The building being found inadequate to contain the number of ftudents that applied, a large addition has been made to it. Georgetown carries on a fmall trade with Europe and the W. Indies. The exports in one year, ending Sept. 30, 1794, amounted to the value of 128,924 dollars. It is 46 miles S. W. by W. of Baltimore, and 148 S. W. of Philadelphia.—*ib.*

Georgetown, in Lincoln co. diftrict of Maine, is fituated on both fides of Kenebeck river. It was incorporated in 1716, is the oldeft town in the county, and contains 1333 inhabitants. It is bounded foutherly by the ocean, wefterly by the towns of Harpfwell and Brunfwick, N. wefterly by Bath, and eafterly by Woolwich; being entirely furrounded by navigable waters, excepting about 2 miles of land, which divides the waters of Winnagance creek, a part of the Kennebeck, from an arm or influx of Cafco bay, called Stephen's river.

The entrance at the mouth of Kennebeck river, is guided on the E. by Parker's ifland, belonging to this townfhip. It contains about 28,000 acres of land and falt marfh, and is inhabited by more than one third part of the people of the townfhip. This was the fpot on which the Europeans firft attempted to colonize New-England, in the year 1607. It is a part of what was called Sagadahock; and the patentees of the Plymouth company began here to lay the foundation of a great ftate. They fent over a number of civil and military officers, and about 100 people. By various misfortunes they were forced to give up the fettlement, and in 1608, the whole number who furvived the winter returned to England.

There was a tradition among the Norridgewalk Indians, that thefe planters invited a number of the natives, who had come to trade with them, to draw a fmall cannon by a rope, and that when they were ranged in a line, the white people difcharged the piece, and thereby killed and wounded feveral of them. The refentment of the natives at this treacherous murder, obliged the Europeans to reimbark the next fummer. Georgetown is 15 miles S. of Pownalborough, and 170 N. by E. of Bofton.—*ib.*

Georgetown, a poft town of Georgia, in the co. of Oglethorpe, 50 miles S. W. of Augufta, furrounded by a poor country; but, neverthelefs, exhibits marks of growing profperity.—*ib.*

Georgetown, a large maritime diftrict in the lower country of S. Carolina, fituated in the S. E. corner of the ftate; bounded N. E. by the ftate of N Carolina, S. E. by the ocean, S. W. by Santee river, which divides it from Charlefton diftrict, and N. W. by Camden and Cheraw diftricts. It is about 112 miles from N. to S. and 63 from E. to W. and is divided into the parifhes of All Saints, Prince George, and Prince Frederick. It contains, according to the cenfus of 1790, 22,122 inhabitants, of whom 13,131 are flaves. It fends to the ftate legiflature 10 reprefentatives and 3 fenators, and pays taxes to the amount of £.3585-12-6. —*ib.*

Georgetown, a poft town, port of entry, and capital of the above diftrict, is fituated on a fpot near which feveral ftreams unite their waters, and form a broad ftream called Winyaw bay, 12 miles from the fea. Its fituation connects it with an extenfive back country of both the Carolinas, and would be a place of vaft importance, were it not for a bar at the entrance of Winyaw bay, which interrupts the entrance of veffels drawing above 11 feet water, and is in many refpects a dangerous place. It contains above 300 houfes, built chiefly of wood. The public buildings are a court-houfe, gaol, and academy; 3 churches, of which the Epifcopalians, Baptifts, and Methodifts have one each. There is here a fmall trade to the Weft-Indies. The exports for one year, ending Sept. 30, 1795, were to the value of 21,511 dollars. It is 60 miles N. E. by N. of Charlefton, 127 S. W. of Wilmington, N. Carolina, and 681 from Philadelphia. N. lat. 33. 24. W. long. 79. 35.—*ib.*

GEORGIA WESTERN TERRITORY. Under this name is included all that part of the State of Georgia which lies weft of the head waters of thofe rivers which fall into the Atlantic Ocean. This extenfive tract of country embraces fome of the fineft land in the United States, is interfected with a great number of noble rivers, which may be feen by an infpection of the map, and is inhabited (except fuch parts wherein the Indian title has been extinguifhed) by three nations of Indians, viz. the Mufkogulge or Creek, the Chactaws, and Chicafaws. The Cherokees alfo have a title to a fmall portion of the northern part of this territory, on the Tenneffee river. Thefe nations together can furnifh between 8 and 9000 warriors. About 2000 families of white people inhabit thofe parts of this territory where the Indian title has been extinguifhed, chiefly at the Natchez, and the Yazoo river, on the banks of the Miffiffippi, and a confiderable number on the Tombigbee river, and fcattered among the Creek Indians. This territory, for reafons which will hereafter appear, has lately become an object of much public attention and inquiry, in Europe, as well as in the United States; and on this account, the following defcription of it and ftatement of facts relative

to

Georgia Western Territory.

to the sale of certain parts of it, and the claims of the United States, &c. have been collected and arranged with great care from the most authentic sources that can be obtained, and given under this head for the information of the public (A). This Territory, lying between the 31st and 35th degrees of N. latitude, is not subject to the extremes of heat or cold; the climate is temperate and delightful through the year; and except in low grounds, and in the neighbourhood of stagnant waters, is very healthful. White frosts, and sometimes thin ice, have been seen as far S. as the 31st degree of latitude; but snow is very uncommon in any part of this territory. A person residing at the Natchez writes to his friend, in the eastern part of Georgia, that "this country affords the best spring water; every person almost is in blooming health." (B) Others who have visited it, say of that part of the territory which borders on the Mississippi, that "the water is good for 20 miles back from the river, and the country healthy and pleasant, and of all others that they have seen the most desirable." Mr Hutchins, speaking of the same tract, says, "the climate is healthy and temperate, the country delightful and well watered, and the prospect is beautiful and extensive; variegated by many inequalities, and fine meadows, separated by innumerable copses, the trees of which are of different kinds, but mostly of walnut and oak. The elevated, open, and airy situation of this country, renders it less liable to fevers and agues (the only disorders ever known in its neighbourhood) than some other parts bordering on the Mississippi, where the want of a sufficient descent to convey the waters off, occasions numbers of stagnant ponds whose exhalations infect the air." Another traveller describes the country between the Tombigbee and the Coosa and Alabama as being healthy, well watered with many pleasant rivulets, affording delightful situations for settlements, and the water pure and very good.

To give a just view of the rivers, and to ascertain the advantages derived from them to this Territory, it is necessary to trace them from their mouths in the Gulf of Mexico. The Mississippi bounds this territory on the W. The free navigation of this noble river is now enjoyed by the inhabitants of the United States. It empties, by several mouths of different depths, from 9 to 16 feet, into the Gulf of Mexico, in about lat. 29 N. The bars at the mouth of this river frequently shift; after passing them into the river, there is from 3 to 10 fathoms of water, as far as the S. W. pass; and thence to the Missouri, a distance of 1,142 computed miles, from 12, 15, 20, and 30 fathoms is the general depth.

In ascending the Mississippi there are extensive natural meadows, with a prospect of the Gulf of Mexico on each side, the distance of 32 miles, to a place called Detour-aux-Plaquemines, in W. Florida. Thence 20 miles to the settlements, the banks are low and marshy, generally overflowed and covered with thick wood, palmetto bushes, &c. apparently impenetrable by man or beast. Thence to Detour-des Anglois, at the bend of the river, the banks are well inhabited; as also from hence to New-Orleans 18 miles, which distance there is a good road for carriages. Vessels pass from the mouth of this river to New-Orleans 105 miles, in 7 or 8 days, commonly; sometimes in 3 or 4.

From New-Orleans, the capital of Louisiana, there is an easy communication with West Florida by Bayouk Creek, which is a water of lake Ponchartrain, navigable for vessels drawing four feet water, six miles up from the lake, to a landing-place two miles from New-Orleans For nearly 50 miles, as you proceed up the river, both its banks are settled and highly cultivated, in part by emigrants from Germany, who furnish the market with indigo of a superior quality, cotton, rice, beans, myrtle wax, and lumber. In 1762, some rich planters attempted the cultivation of canes and the making of sugar, and erected mills for the purpose. This sugar was of an excellent quality, and, some of the crops were large; but some winters proving so severe as to kill the canes, no dependence can be placed on the culture of that article.

The settlements of the Acadians, which were begun in the year 1763, extend on both sides of the river, from the Germans, to the river Ibberville, which is 99 miles

(A) The sources whence the author has derived his information, in drawing up the following account, are Capt. Thomas Hutchins's "Historical narrative and topographical description of Louisiana and West-Florida," comprehending also many of the rivers and settlements in the Georgia Western Territory; published in 1784. Private letters and journals; minutes taken from verbal descriptions of gentlemen of veracity and intelligence who have resided in that country. The journals and laws of the State of Georgia—State papers, and Reports both printed and M. S. of Congress, and of Agents of the several companies who have purchased lands in this territory.

(B) The letter here alluded to contains the following paragraphs: "Our navigation is excellent: our high lands preferable to Beach Island, (1) when in its bloom; stock is as easy come at as where you are: lands are rising fast, and I expect will be very high in a few years. The canes in common, on the high lands, larger than in the river-swamps, [meaning in the eastern part of Georgia] from 30 to 35 feet high, and upwards, and in many places stand so thick, that one can scarcely walk a mile in half an hour. Some families must be coming to this most flourishing country in the world. I wish you to advise any of my relations you see to come with all haste: if they can get here, and are turned out naked in the world, in one year they might be fixed again. I am sure could I have time to say as much as I wish to say, you would be with me this fall. I could venture to almost promise, if you would be wise and come, to make good any deficiencies you might find in the place." The author is in possession of the original letter, above mentioned, which has every mark of authenticity; and the above extracts are inserted, as containing the simple, honest description of a plain farmer; on which more dependence is to be placed, than on the most elaborate and elegant descriptions of interested narrators.

(1) Alluding to a remarkably fertile island in the eastern part of Georgia, in the neighbourhood of the writer's correspondent, and with which both were well acquainted.

Georgia Western Territory.

miles above New-Orleans, and 270 from Pensacola, by way of lakes Ponchartrain and Maurepas.

At Point Coupee, 35 miles above the Ibberville, are settlements extending 20 miles on the W. side of the river, which, 30 years ago, had 2,000 white inhabitants, and 7,000 slaves, who were employed in the cultivation of tobacco, indigo, Indian corn, &c. for the New-Orleans market, which they furnished also with poultry, and abundance of squared timber, staves, &c.

Mr Hutchins, from his personal knowledge, describes the country on both sides of the Mississippi, between the latitudes 30 and 31, bordering on Georgia, as follows:

"Although this country might produce all the valuable articles raised in other parts of the globe, situated in the same latitudes, yet the inhabitants principally cultivate indigo, rice, tobacco, Indian corn, and some wheat; and they raise large flocks of black cattle, horses, mules, hogs, sheep and poultry. The sheep are said to make the sweetest mutton in the world. The black cattle, when fat enough for sale, which they commonly are the year round, are driven across the country to New-Orleans, where there is always a good market.

This country is principally timbered with all the different kinds of oak, but mostly with live-oak, of the largest and best quality, uncommonly large cypress, black walnut, hickory, white ash, cherry, plum, poplar trees, and grape vines; here is found also a great variety of shrubs and medicinal roots. The lands bordering the rivers and lakes, are generally well wooded, but at a small distance from them are very extensive natural meadows, or savannas, of the most luxuriant soil, composed of a black mould, about one and a half feet deep, very loose and rich, occasioned in part, by the frequent burning of the savannas; below the black mould is a stiff clay of different colours. It is said, this clay, after being exposed some time to the sun, becomes so hard, that it is difficult either to break or bend, but when wet by a light shower of rain, it slackens in the same manner as lime does when exposed to moisture, and becomes loose and moulders away, after which it is found excellent for vegetation."

After passing the 31st degree of N. lat. from W. Florida into Georgia, you enter what is called the *Natchez Country*, bordering on the Mississippi. Fort Rosalie, in this country, is in lat. 31 40, 243 miles above New-Orleans.

"The soil of this country is superior to any of the lands on the borders of the river Mississippi, for the production of many articles. Its situation being higher, affords a greater variety of soil, and is in a more favourable climate for the growth of wheat, rye, barley, oats, &c. than the country lower down, and nearer to the sea. The soil also produces in equal abundance, Indian corn, rice, hemp, flax, indigo, cotton, pot-herbs, pulse of every kind, and pasturage; and the tobacco made here, is esteemed preferable to any cultivated in other parts of America. Hops grow wild; all kinds of European fruits arrive to great perfection, and no part of the known world is more favourable for the raising of every kind of stock. The rising grounds, which are cloathed with grass and other herbs of the finest verdure, are well adapted to the culture of vines: the mulberry trees are very numerous, and the winters sufficiently moderate for the breed of silk worms. Clay of different colours, fit for glass works and pottery, is found here in great abundance; and also a variety of stately timber, fit for house and ship building, &c."

Another gentleman, well informed, (c) says, "The lands on the Mississippi, extending eastward about 20 miles, are hilly, without stones or sand, extremely rich, of a deep black soil, covered thick with canes, white and black oak, walnut, hickory, ash, some sugar maple, beech, and dogwood; that there are very few streams or springs of water; that the water is not good, and tastes as if impregnated with sulphur; that the country is much infested with insects; that the land is high and bluff three-fourths of the distance along the river Mississippi, and a part overflowed and drowned." But it is apprehended that this description is not perfectly just, so far as it applies to the scarcity and badness of the water; as a gentleman of respectable character, who resided 9 months at the Natchez, says, "The lands on the Mississippi are more level, and better watered, than is above represented; and that the water is good, and the country healthy and remarkably pleasant."

This country was once famous for its inhabitants, the Natchez Indians; who, from their great numbers, and the improved state of society among them, were considered as the most civilized Indians on the continent of America. Nothing now remains of this nation but their name, by which their country continues to be called. The district of the Natchez, as well as all along the eastern bank of the Mississippi to the river Ibberville, was settling very fast by emigrations from the northern States, till the capture of the British troops on the Mississippi, 1779, put an entire stop to it.

"From fort Rosalie to the Petit Goufre is 31½ miles. There is a firm rock on the east side of the Mississippi for near a mile, which seems to be of the nature of lime-stone. The land near the river is much broken and very high, with a good soil, and several plantations on it. From the Petit Goufre to Stoney river, is 4½ miles. From the mouth to what is called the fork of this river, is computed to be 21 miles. In this distance there are several quarries of stone, and the land has a clay soil, with gravel on the surface of the ground. On the north side of this river, the land in general is low and rich; that on the south side is much higher, but broken into hills and vales; but here the low lands are not often overflowed; both sides are shaded with a variety of useful timber. At the fork, the river parts almost at right angles, and the lands between and on each side of them are said to be clay and marl soil, not so uneven as the lands on this river lower down. From Stony river to Loufa Chitto, or Big Black river, is 10 miles. This river, at the mouth, is about 30 yards wide, but within, from 30 to 50 yards, and is said to be navigable for canoes 30 or 40 leagues. About a mile

(c) Mr Isaac Perry, of Burk county, Georgia.

mile and a half up this river, the high lands are cloſe on the right, and are much broken. A mile and a half further, the high lands appear again on the right, where there are ſeveral ſprings of water, but none as yet have been diſcovered on the left. At about 8 miles further, the high lands are near the river, on the left, and appear to be the ſame range that comes from the Yazoo cliffs. At ſix miles further, the high lands are near the river on both ſides, and continue for two or three miles, but broken and full of ſprings of water. This land on the left was choſen by Gen. Putnam, Capt. Enos, Mr Lyman, and other New-England adventurers, as a proper place for a town; and, by order of the governor and council of Weſt-Florida, in 1773, it was reſerved for the capital. The country round is very fit for ſettlements. For four or five miles above this place, on both ſides of the river, the land is rich, and not ſo much drowned, nor ſo uneven, as ſome parts lower down. About ſix miles and a half further, there is a rapid water, ſtones and gravel bottom, 160 yards in length; and in one place a firm rock almoſt acroſs the river, and as much of it bare, when the water is at a moderate height, as confines the ſtream to nearly 20 feet; and the channel is about four feet deep.

From the Louſa Chitto to the Yazoo Cliffs, is 40 miles. From this cliff the high lands lie north-eaſtward and ſouth-ſouth-eaſtward, bearing off from the river, full of cane and rich ſoil, even on the very higheſt ridges. Juſt at the S. end of the cliffs, the bank is low, where the water of the Miſſiſſippi, when high, flows back and runs between the bank and high land, which ranges nearly northerly and ſouth-ſouth eaſterly to the Louſa Chitto, occaſioning much wet ground, cypreſs ſwamp, and ſtagnant ponds. From the Cliffs, is ſeven miles and a half to the river Yazoo. The mouth of this river is upwards of 100 yards in width, and was found by Mr Gaul to be in lat. 32 37, and by Mr Purcell in 32 28 N. The water of the Miſſiſſippi, when the river is high, runs up the Yazoo ſeveral miles, and empties itſelf again by a number of channels, which direct their courſe acroſs the country, and fall in above the Walnut Hills. The Yazoo runs from the N. E. and glides through a healthy, fertile and pleaſant country, greatly reſembling that about the Natchez, particularly in the luxuriancy and diverſity of its ſoil, variety of timber, temperature of climate, and delightful ſituation. It is remarkably well watered by ſprings and brooks; many of the latter afford convenient ſeats for mills. Further up this river the canes are leſs frequent, and ſmaller in ſize, and at the diſtance of 20 miles there are ſcarcely any. Here the country is clear of underwood, and well watered, and the ſoil very rich, which continues to the Chactaw and Chickaſaw towns, on the eaſtern and north-weſtern branches of Yazoo river. Theſe branches unite 50 miles from the Miſſiſſippi, following the courſe of the river; the navigation to their junction, commonly called the Fork, is practicable with very large boats in the ſpring ſeaſon, and with ſmaller ones a conſiderable way further, with the interruption of but one fall, where they are obliged to make a ſhort portage, 20 miles up the N. W. branch, and 70 miles from the Miſſiſſippi. The country in which the Chactaw and Chickaſaw towns are ſituated, is ſaid to be as healthy as any part of the continent, the natives ſcarcely ever being ſick. Such of them as frequent the Miſſiſſippi, leave its banks as the ſummer approaches, leſt they might partake of the fevers that ſometimes viſit the low, ſwampy lands bordering upon that river. Wheat, it is ſaid, yields better at the Yazoo than at the Natchez, owing probably to its more northern ſituation. One very conſiderable advantage will attend the ſettlers on the river Yazoo, which thoſe at the Natchez will be deprived of, without going to a great expenſe; that is, the building with ſtone, there being great plenty near the Yazoo, but none has yet been diſcovered nearer to the Natchez than the Petit Goufre, or Little Whirlpool, a diſtance of about 31 miles. Between this place and the Balize, there is not a ſtone to be ſeen any where near the river. Though the quantity of good land on the Miſſiſſippi and its branches, from the Bay of Mexico to the river Ohio, a diſtance of nearly one thouſand miles, is vaſtly great, and the conveniences attending it; ſo likewiſe we may eſteem that in the neighbourhood of the Natchez, and of the river Yazoo, the flower of it all.

About a mile and a half up the Yazoo river, on the N. ſide, there is a large creek, which communicates with the Miſſiſſippi above the river St Francis, about 100 leagues higher up, by the courſe of the river. It paſſes through ſeveral lakes by the way. At the diſtance of 12 miles from the mouth of the river Yazoo, on the S. ſide, are the Yazoo hills. There is a cliff of ſolid rock at the landing place, on which are a variety of broken pieces of ſea ſhells, and ſome entire. Four miles further up, is the place called the Ball Ground, near which a church, fort St Peter, and a French ſettlement, formerly ſtood. They were deſtroyed by the Yazoo Indians in 1729. That nation is now entirely extinct." [*Hutchins.*]

From about 20 miles eaſtward of the Miſſiſſippi, to Half way or Pearl river, the diſtance of about 60 miles, (ſome ſay leſs) is "a fine, level country, very fertile, and better watered than nearer the Miſſiſſippi. There is ſome mixture of ſand with loam, the timber the ſame, with the addition of black-jack, and poſt-oak. This tract is interſperſed with what the French call *Prairies* or *Savannas*, which are extenſive intervals of 1,000 and 2,000 acres of excellent land, of a deep black ſoil, free of all timber and trees. It is this kind of land which the Indians cultivate. From the Miſſiſſippi to this river, there are no Indians. To a tract of this country, extending along the Miſſiſſippi from the 31ſt degree of latitude to the Yazoo river, at the S. end, 30 miles wide, and narrowing as you proceed northerly to the width of 15 miles, the Indian title has been extinguiſhed. It was at firſt purchaſed by the Engliſh; but they, not having completed the payment for it, before it fell into the hands of the Spaniards, they, (the Spaniards) in the year 1792, paid the balance. At Walnut Hills, the Spaniards have a fort, which, according to treaty, is to be given up (if not already done) to the United States. To the country N. of the Yazoo, the Indian title is not yet extinguiſhed. About one half of the ſouthern part, a diſtance of about 50 miles up the Yazoo, is owned by the Chactaws, the northern half by the Chickaſaws." The gentleman who gives the above information, and who was in this country in the year 1792, ſays, "that the Yazoo is about 50 yards wide; is boatable 100 miles; that he croſſed the country by different routes, 3 or 4 times from the Miſſiſippi to the Tombigbee; paſſed over the Yazoo ſeveral times; went up and down the river on the ſhore, and ſays that the lands to the E of the Yazoo (the diſtance of about 100 miles) are very excellent"

Pearl river is about 40 yards wide; a branch of it paſſing E. of the Natchez and neareſt, in Coxe's map, bears the name of Buffaloe river. On the E. ſide of Pearl river, commence the Chactaw ſettlements, and extend thick to the Chickataw Hay river; thence, about 40 miles eaſtward, the ſettlements are ſparſe, and extend near to the Tombigbee. This is a numerous nation, containing about 3000 hunters, a peaceable and friendly people. The country inhabited by theſe Indians is noted in Coxe's map, to be "poor and barren land, covered generally with long leafed pine." Other accounts repreſent it as much the ſame as that between the Miſſiſippi and Pearl rivers, with the addition of ſome pine land, and better watered. The ſtreams on which the Chactaws are ſettled, as laid down on Coxe's map, are, proceeding from W. to E. the Homachitta, (called by Purcell Hoſtaphatcha) Chactaw, and Souhawtee, which unite, and the main ſtream retains the name of Homachitta till it empties into the Gulf of Mexico. This is probably the ſame river that Hutchins calls Paſcagoula. The head branches of this river ſpread extenſively through the northern part of this Territory, chiefly weſtward of the Chactaw nation. White, or Bluff river, on Coxe's map, appears to riſe in about lat. 33. N. takes a courſe to the E. of the Chactaws, and empties into the Tombigbee, ſome diſtance below the head of the tide water, and is laid down as about the ſize of Pearl river.

From the compact ſettlements of the Chactaws eaſtward to the weſtern branches of the Tombigbee, the land is tolerably good; the timber generally oak and pine, with ſome hickory, well watered and level. Of this kind is the country a diſtance of about 40 miles W. of the weſtern branches of the Tombigbee; thence to the Tombigbee, the land is more uneven, interſperſed with large ſavannas, and the whole generally good land, and pretty well watered; the water, however, has a limy taſte. The natural growth much the ſame as on the Miſſiſippi. The intervale, or as they call it in this country, the *bottom lands*, are generally about a mile wide on the river, extremely rich, and thickly overgrown with canes. This general deſcription will apply to the whole tract belonging to the "Georgia Miſſiſſippi Company." Mr Coxe, on his map, remarks that, "On the Tombigbee and Alabama rivers there are bodies of fine rich land, but low down, towards Mobile Bay, unhealthy."

We have now arrived eaſtward to the Mobile, the principal river in this territory. "On the bar at the entrance of the bay of Mobile, there is only about 15 or 16 feet water; two-thirds of the way through the bay, towards the town of Mobile, there is from 2 to 3 fathoms; and the deepeſt water to be depended on in the upper part of the bay is only 10 or 12 feet, and in many places not ſo much. Large veſſels cannot go within 7 miles of the town." [*Hutchins.*] "This bay is about 30 miles long, and from 10 to 12 wide. The tide flows 60 or 70 miles above this bay, and is ſo far navigable for ſea veſſels. Thence 150 or 200 miles north, is good boat navigation, ſmooth water, generally 100 to 150 yards wide, and 8 to 10 feet deep." [*M. S. Minutes from Mr Perry*] "The bay of Mobile terminates a little to the north eaſtward of the town, in a number of marſhes and lagoons; which ſubject the people to fevers and agues, in the hot ſeaſon.(A) The river Mobile, as you aſcend it, divides into 2 principal branches, about 40 miles above the town; one of which, called the Tanſaw, falls into the eaſt part of the bay; the other empties itſelf cloſe by the town, where it has a bar of 7 feet; but there is a branch a little to the eaſtward of this, called Spaniſh river, where there is a channel of 9 or 10 feet, when the water is high; but this joins Mobile river about 2 leagues above the town. Two or three leagues above the Tanſaw branch, the Alabama river falls into Mobile river, after running from the north-eaſt a courſe of about 130 miles; that is, from Alabama fort, ſituated at the confluence of the Cooſa, and Talipooſee, both very conſiderable rivers; on which and their branches are the chief ſettlements of the Upper Creek Indians. The French fort at Alabama was evacuated 1763, and has not ſince been garriſoned. Above the confluence of Alabama and Mobile, the latter is called the Tombigbee river, from the fort of Tombigbee, ſituated on the weſt ſide of it, about 96 leagues above the town of Mobile. The ſource of this river is reckoned to be about 40 leagues higher up, in the country of the Chickaſaws. The fort of Tombigbee was taken poſſeſſion of by the Engliſh, but abandoned again in 1767, by order of the commandant of Penſacola. The river is navigable for ſloops and ſchooners about 35 leagues above the town of Mobile. The banks, where low, are partly overflowed in the rainy ſeaſons, which adds greatly to the ſoil, and adapts it particularly to the cultivation of rice. The ſides of the river are covered in many places with large canes, ſo thick that they are almoſt impenetrable; there is alſo plenty of remarkable large red and white cedar, cypreſs, elm, aſh, hickory, and various kinds of oak. Several people have ſettled on this river, who find the ſoil to anſwer beyond expectation. The lands near the mouth of the Mobile river are generally low; as you proceed upwards, the land grows higher, and may with propriety be divided into three ſtages. Firſt, low rice lands, on or near the banks of the river, of a moſt excellent quality. Secondly, what are called by the people of the country, ſecond low lands, or level flat cane lands, about 4 or 5 feet higher than the low rice lands. And, thirdly, the high upland or open country. The firſt, or low lands, extend about an half or three-quarters of a mile from the river, and may almoſt every where be eaſily drained and turned into moſt excellent rice fields, and are capable of being laid under water at almoſt all ſeaſons of the year. They are a deep black mud or ſlime, which have in a ſucceſſion of time been accumulated, or formed by the overflowing of the river. The ſecond low grounds being, in general, formed by a regular riſing of about

---

(A) Mr Coxe, in his map, extends Mobile Bay ſome diſtance north of the 31ſt degree of latitude. Other accounts ſay this bay does not extend into the State of Georgia.

Georgia Western Territory.

4 or 5 feet higher than the low lands, appear to have been originally the edge of the river. The second class or kind of land is in general extremely rich, and covered with large timber and thick strong canes, extending in width upon an average three-quarters of a mile, and in general a perfect level. It is excellent for all kinds of grain, and well calculated for the culture of indigo, hemp, flax, or tobacco. At the extremity of these second grounds, you come to what is called the high or uplands, which is covered with pine, oak, and hickory, and other kinds of large timber. The soil is of a good quality, but much inferior to the second or low land. It answers well for raising Indian corn, potatoes, and every thing else that delights in a dry soil. Further out in the country again, on the west side of this river, you come to a pine barren, with extensive reed swamps and natural meadows or savannas, which afford excellent ranges for innumerable herds of cattle. On the east of the river Mobile, towards the river Alabama, is one entire extended rich cane country, not inferior, perhaps, to any in America. Whenever portages are made between the Mobile and Tennessee river, or their branches, which are probably but a few miles apart, the Mobile will be the first river for commerce (the Mississippi excepted) in this part of the world, as it affords the shortest and most direct communication to the sea." [*Hutchins.*]

In addition to, and confirmation of, the above account of Capt. Hutchins, several other gentlemen of intelligence who have been in this country, say that "the Tombigbee is navigable for sea vessels 60 miles into the State of Georgia;" (B) others, that "it is navigable in boats of 20 tons up to the junction of 10 and 20 Mile Creek. The Alabama and Coosa are navigable for boats of 40 tons, as high as the big shoals of Coosa river. The principal rivers which meander through this tract of country, are Seprey's and Cane Brake rivers, both which fall into the Tombigbee, and are navigable for boats as high as the 33d degree of latitude; and the Cawhawbon river, which falls into Alabama river, below the junction of Coosa and Oakfuskee, are boatable as far N. as the rivers last mentioned. The soil on the E. side of Tombigbee, is of a reddish cast, producing naturally oak, hickory, and abundance of very high grass. The country appears well calculated for the culture of wheat, corn, rye, oats, and barley. The bottoms or intervales on the rivers are not subject to inundations, and are exceedingly rich. The country is well watered with good wholesome water. Further north, the country becomes uneven and somewhat hilly, that part particularly which divides the waters of Tombigbee from Tennessee river, but as you descend to a lower latitude, the country is more level; and down about the mouth of Cane Brake river, and thence across to the Alabama, is almost one entire cane brake."

"The ridge which divides the Tombigbee and Alabama rivers is stony, and the soil inferior to that on the rivers; of this description also is the country lying between the Cawhawbon and Alabama rivers; but the bottom lands on the water courses are exceedingly rich. The country is pleasant and healthy, being generally overgrown with high grass, well calculated for farming, particularly for raising cattle. There are many extensive and rich bottoms of cane land on the Alabama. The river which falls into the Tombigbee next above Seprey's river, has much rich land on its banks, and is boatable some distance in small boats, and spreads into many branches, through a pleasant, healthy, and well watered country." [*Coxe's M. S. Letter.*] As you advance eastward of the Alabama, in the Territory we are describing, you come first to the Escambia river, and then to the Chatta Hatcha, or Pea river, which Capt. Hutchins thus describes—"The river Escambia is the most considerable that falls into the Bay of Pensacola. The Chatta Hatcha or Pea river, which also heads in the Georgia Western Territory, empties from the N. E. into Rose bay, which is 30 miles long and from 4 to 6 broad. The bar at the entrance into the bay has only 7 or 8 feet water, at deepest; but, after crossing the bar, has 16 or 17 feet. The mouths of the river (for almost all the southern rivers have several mouths) are so shoal, that only a small boat or canoe can pass them. Mr Hutchins ascended this river about 75 miles, and found that its banks very much resembled those of Escambia. Further east are the Appalachicola, Flint, and Alabama rivers, which are described under their respective heads.

The northern parts of this Territory are watered by the great bend of the Tennessee, and its tributary streams. This noble river bends southward as far as latitude 34. 15 according to Capt. Hutchins' map, and divides, into nearly equal parts, the purchase of the *Tennessee Company*. North of the Tennessee, in this purchase, there is not an Indian inhabitant. From the south, the Tennessee, in its course through Georgia, receives, besides smaller streams, the Hiwassee, Chiccamauga, and Occochappo or Bear Creek. Travellers speak of the lands on the bend of the Tennessee, in terms of the highest commendation.

Of the Territory described above, the State of Georgia, by act of their legislature, passed Jan. 7, 1795, sold about twenty-two millions of acres to four different companies, whose names and the limits of their respective purchases, as defined by the act, follow.

1. "All that tract or parcel of land including islands, beginning on Mobile bay, where the lat. 31. N. of the equator intersects the same, running thence up the said bay to the mouth of the lake Tensaw; thence up the said lake Tensaw, to the Alabama river, including Curreys and all other islands therein; thence up the said river Alabama, to the junction of the Coosa and Oakfuskee rivers; thence up the Coosa river, above the Big Shoals, to where it intersects the latitude of 34. N. of the equator; thence a due W. course to the Mississippi river; thence down the middle of the said river, to the latitude of 32. 40.; thence a due E. course to the Dan or Tombigbee river; thence down the middle of the said river to its junction with the Alabama river; thence down the middle of the said river to Mobile Bay; thence down the said Mobile Bay, to the place of beginning, shall be sold unto James

(B) Col. Hammond, late surveyor gen. of Georgia.

James Gunn, Matthew M'Alliſter, and George Walker, and their aſſociates, called *The Georgia Company.*"

2. "All that tract of country, including iſlands, within the following boundaries, viz. beginning on the river Miſſiſſippi, at 31. 18. N. lat. thence a due E. courſe to the middle of Dan or Tombigbee river; thence up the middle of the ſaid river to N. lat. 32. 40; thence a due W. courſe along the Georgia Company line, to the river Miſſiſſippi; thence down the middle of the ſame, to the place of beginning, ſhall be ſold to Nicholas Long, Thomas Glaſſcock, Ambroſe Gordon, and Thomas Cummings, and their aſſociates, called *The Georgia Miſſiſſippi Company.*"

3. "All that tract of country, including iſlands, within the following boundaries, viz. beginning at the Miſſiſſippi river, where the northern boundary line of the State ſtrikes the ſame; thence along the ſaid northern boundary line, due E. to the Tenneſſee river; thence along the ſaid Tenneſſee river, to the mouth of Bear Creek; thence up Bear Creek, to where the parallel of latitude 25 Britiſh ſtatute miles S. of the northern boundary line of the State interſects the ſame; thence along the laſt mentioned parallel of latitude, acroſs Tombigbee or Twenty Mile Creek, due W. to the Miſſiſſippi river; thence up the middle of the ſaid river, to the beginning, ſhall be ſold to John B. Scott, John C. Nightingale, and Wade Hampton, called *The Upper Miſſiſſippi Company.*"

4. "All that tract of land, including iſlands, within the following boundaries, viz. beginning at the mouth of Bear Creek, on the S. ſide of Tenneſſee river; thence up the ſaid creek to the moſt ſouthern ſource thereof; thence due S. to lat. 34. 10. N. thence due E. 120 miles; thence a due N. courſe to the Great Tenneſſee river; thence up the middle of the ſaid river to the northern boundary line of the State; thence a due W. courſe along the ſaid line to where it interſects the Great Tenneſſee river, below the Muſcle Shoals; thence up the ſaid river to the place of beginning, ſhall be ſold to Zachariah Cox, Mathias Maher, and their aſſociates, called *The Tenneſſee Company.*"

The ſame law enacts alſo, "that all lands lying weſtward and ſouthward of the eaſtern boundary of the ſeveral Companies' purchaſes, and not included therein, eſtimated at one fourth of the whole lands lying weſtward and ſouthward of the eaſtern boundary of the ſaid purchaſes, and ſuppoſed to contain 7,250 000 acres, ſhall be, and the ſame is hereby declared to be reſerved and ſet apart to, and for the uſe and benefit of this State, to be granted out, or otherwiſe diſpoſed of, as future legiſlatures may direct." [*Act of Georgia Legiſlature of Jan. 7th, 1795.*]

The purchaſe-mony, amounting to 500,000 dollars, was duly paid by the reſpective Companies, into the State treaſury of Georgia, agreeably to the terms of the act. This land was ſoon after ſold by the original Companies, to various gentlemen, principally in the Middle and Eaſtern States. The ſale of this territory excited a warm and violent oppoſition in Georgia. The act authoriſing this ſale, was by certain leading men in the State, declared to be "an uſurped act,—repugnant to the principles of the Federal Conſtitution, and of the Conſtitution of Georgia—oppoſed to the good of the ſtate, and obtained by fraud, atrocious ſpeculation, corruption and colluſion." In conſequence of theſe repreſentations, a determination was formed by a powerful party, to ſet aſide and annul, at the ſucceeding ſeſſion of the legiſlature, this offenſive, "uſurped act." Efforts were accordingly made, and with ſucceſs, to obtain a legiſlature ſuited to the accompliſhment of their deſigns. Accordingly, on the 13th of Feb. 1796, an act was paſſed declaring the above-mentioned "uſurped act" null and void; and all the grants, rights and claims ariſing there-from, of no validity or effect; and that the ſaid territory was the ſole property of the State." To complete the utter annihilation of this odious act, as far as poſſible, the legiſlature ordered, that, in their preſence, and that of the public officers of the State, the ſeveral records, documents and deeds, in the ſeveral public offices, ſhould be "expunged from the faces and indexes of the books of record of the State; and the enrolled law, or uſurped act, publickly burnt." All this was accompliſhed three days after the paſſing of the act. Theſe unprecedented proceedings were attended and followed with moſt diſagreeable and tumultuary effects. The original purchaſers of theſe lands, the then holders, and all thoſe who had been intermediately concerned, who had by this time become a numerous and reſpectable body, ſcattered through the United States, were, for the moment, thrown into an unpleaſant dilemma, and for a time this buſineſs was the general topic of converſation. The title to the lands purchaſed by the above named companies, has been ſtill further embarraſſed by a claim brought forward in behalf of the United States.—*ib.*

GEORGIA, a townſhip in Franklin co. Vermont, contains 340 inhabitants. It is ſituated on Lake Champlain, oppoſite to the N. end of South Hero Iſland, and joins Milton on the S. and St Alban's on the north. La Moille river croſſes the extremity of the S. E. corner of this townſhip.—*ib.*

GEORGIA, *Southern*, a cluſter of barren iſlands, in the South Sea, and E. of the coaſt of Terra del Fuego; about lat. 54. 35. S. and long. 36. 30. W. One of them is between 50 and 60 leagues in length. —*ib.*

GEORGIUM SIDUS (ſee ASTRONOMY-*Index*, *Encycl*,) has no fewer than ſix ſatellites revolving round it, all diſcovered by Dr Herſchel. Of the two which he firſt diſcovered, one was found to revolve in 8 days 17 h. 1 m. 17 ſec. at the diſtance of 33″ from its primary; and the other in 13 d. 11 h. 5 m. 1,5 ſec. at the diſtance of 44″,23. The planes of their orbits form ſuch large angles with that of the planet itſelf, and conſequently of the ecliptic, as to be almoſt perpendicular to it. To this remarkable departure from the analogy of the old planets, another ſtill more ſingular has been lately announced. They move in a retrograde direction! The new ſatellites revolve as follows, the periodical times being inferred from their greateſt elongations: The interior ſatellite in 5 d. 21 h. 25 m. at the diſtance of 25″,5. A ſatellite intermediate between the two old ones in 10 d. 23 h. 4m. at the diſtance of 38″,57. The neareſt exterior ſatellite at about double the diſtance of the fartheſt old one, and conſequently its periodical time 38 d. 1 h. 49 m. And the moſt diſtant ſatellite full four times as far from its primary as the

the old ſecond ſatellite. Whence it will take at leaſt 107 d. 16 h. 40 m. to complete its revolution. Whether the motions of theſe four be direct or retrograde, is, we ſuppoſe, not yet determined.

From ſome obſervations of the Doctor, with an excellent ſeven-feet teleſcope, certain appearances reſembling that of two rings ſurrounding the planet, and croſſing each other at right angles, were ſeen on ſeveral different days. They were not altered in poſition by turning the ſpeculum in its cell; but (ſays Mr Nicholſon) there is little doubt that they were optical deceptions, becauſe they kept their poſition with reſpect to the tube, after the relative poſition of the parallel had been much changed by the earth's rotation, and becauſe they did not appear with larger teleſcopes applied during the courſe of ten years. The diſk of the Georgium Sidus is flattened. It therefore revolves with conſiderable rapidity on its axis. From the very faint light of the ſatellites, they are obſerved to diſappear in thoſe parts of their orbits which bring them apparently neareſt the planet. This does not ariſe from an atmoſphere; for the effect is the ſame, whether the ſatellite be within or beyond the planet.

GERARD (Alexander, D. D.) was the eldeſt ſon of the reverend Gilbert Gerard miniſter of Chapel-Garioch, in the county of Aberdeen. He was born on the 22d of February, 1728, and received the firſt rudiments of his education at the pariſh ſchool of Foveran in the ſame county.

It may perhaps be proper to inform our readers, that in every pariſh in Scotland there is a ſchool where, for very ſmall fees, the youth of the pariſh are not only taught to read the Engliſh language, to write, and to perform the elementary operations of arithmetic, but are alſo inſtructed in the Greek and Latin languages. Of theſe ſchools, many of the maſters were, about ſixty years ago, eminent for claſſical learning; and it ſeems that Mr Forbes, the maſter of the ſchool of Foveran poſſeſſed ſuch fame as a teacher, that Mr Gerard judged it more expedient to commit his ſon to his care than to have him educated at the ſchool of his own pariſh, and under his own immediate inſpection. The attainments which that ſon afterwards made in literature, evince that his judgment was correct, and that the ſchoolmaſter of Foveran deſerved the fame which he enjoyed.

Young Gerard, however, did not remain long at Foveran. His father died when he was but ten years old; and his mother removing ſoon afterwards with her family to Aberdeen, he was of courſe put to the grammar-ſchool in that city; but ſo ſolid was the foundation which had been already laid, that in two years time he was deemed fit for the univerſity, and was accordingly entered a ſtudent in Mariſchal college. Such rapid progreſs ſupplies the place of that teſtimony which we have not been able to procure, reſpecting his early attachment to literature.

After completing the uſual academical courſe of four years in the ſtudy of Greek, Latin, mathematics, and philoſophy, he was admitted to the degree of maſter of arts; and immediately afterwards commenced the ſtudy of theology, which he proſecuted in the univerſities of Aberdeen and Edinburgh. In 1748, when he had little more than completed his twentieth year, he was licenced to preach in the church of Scotland, and two years afterwards was choſen aſſiſtant to Mr David Fordyce profeſſor of philoſophy in the Mariſchal college and univerſity of Aberdeen. In this capacity he performed the duties of the abſent profeſſor till the 7th of July 1752, when he was appointed ſucceſſor to Mr Fordyce who had been drowned, on the coaſt of Holland, as has been already related in the Encyclopædia.

At that period it was the practice in the Mariſchal college, as it continued to be in the King's, for the ſame profeſſor to carry forward a claſs of ſtudents for three ſucceſſive years, through all the different branches of philoſophy which were taught in the college. Theſe were, LOGIC, ONTOLOGY, PNEUMATICS, MORALS, POLITICS, and NATURAL PHILOSOPHY; and Mr Gerard carried one claſs through this extenſive courſe. MATHEMATICS and the GREEK language were taught by ſeparate profeſſors.

About the year 1754, a very material alteration was made in the *order* of teaching philoſophy in the univerſity of Aberdeen; and in the Mariſchal college each profeſſor was reſtricted to one department of ſcience. The principal and profeſſors in that college, juſtly obſerving that the public is intereſted in every thing which relates to education, thought it incumbent upon them to lay before that public the reaſons which had determined them to deviate from the arrangement which they had hitherto obſerved; and they employed profeſſor Gerard to draw up theſe reaſons. This taſk he performed in a ſmall pamphlet, which, being printed by the appointment of the college, appears to have given very general ſatisfaction.

This, indeed, it could hardly fail to do; for the judicious author points out very clearly the inconveniences of the old, and the advantages of the new plan of academical ſtudy. Having obſerved, that the philoſophy which had ſo long kept poſſeſſion of the ſchools, conſiſted, in a great meaſure, of verbal ſubtleties and theories ill-grounded, though ingeniouſly deviſed, he proceeds to contraſt it with the philoſophy of Bacon and Locke, and to ſhow of how little value the former is when compared with the latter. He then enters on a brief examination of the ſcholaſtic logic, and proves, to the conviction of every impartial judge, that the art of ſyllogizing, though a proper enough introduction to a philoſophy which was built on general principles, either taken for granted, or founded on very narrow and inadequate obſervation, is by no means fitted to aſſiſt the mind in the cultivation of that ſcience which is deduced by induction from particular facts. "The only baſis of philoſophy (ſays he) is now acknowledged to be an accurate and extenſive hiſtory of nature, exhibiting an exact view of the various phenomena, for which philoſophy is to account, and on which it is to found its reaſonings. This being the reformed ſtate of philoſophy, great inconveniences muſt be found in proſecuting the ſcholaſtic order of the ſciences. The ſtudent muſt make a tranſition at once from words and languages to philoſophy, without being previouſly introduced to the knowledge of facts, the ſole foundation of, and preparation for it; he muſt be hurried at the firſt into the moſt abſtruſe, difficult, and ſubtle parts of it; he muſt be put upon examining the nature, foundation and different kinds of evidence and reaſoning, before he is acquainted with any ſpecimens of theſe kinds by by which they may be illustrated. And in proportion as philosophy is more improved, and more thoroughly reformed, these inconveniences must become more sensible.

"The view of these (continues he) induced the masters of the Marischal college to think of altering the hitherto received order; and after the most mature deliberation, made them at last resolve, that their students should, after being instructed in languages and classical learning, be made acquainted with the elements of history, natural and civil, of geography and chronology, accompanied with the elements of mathematics; that they should then proceed to natural philosophy; and, last of all, to morals, politics, logic, and metaphysics."

In vindicating this arrangement, he labours with great earnestness, and we think with complete success, to shew the propriety of making logic the last branch of academical study. "All sciences (says he), all departments of knowledge whatever, must be premised as a ground-work to genuine logic. History has one kind of evidence, mathematics another, natural philosophy one still different, the philosophy of human nature another distinct from all these; the subordinate branches of these several parts have still minuter peculiarities in the evidence appropriated to them. An unprejudiced mind will in each of these be convinced by that species of argument which is peculiar to it, though it does not reflect *how* it comes to be convinced. By being conversant in *them*, one is prepared for the study of *logic*; for *they* supply him with a fund of materials; in *them* the different kinds of evidence and argument are exemplified; from *them* only those illustrations can be taken, without which *its* rules and precepts must be unintelligible.

"All just conclusions concerning the works of nature must be founded on an induction of particulars. And as in *natural philosophy* these particulars are supplied by observations and experiments on *natural bodies*; so in *logic*, the particulars, of which an induction must be made, are to be learned only from the body of *arts and sciences*. These are the subjects on which observations must be made, in order to lay down rules for investigating and proving the truths of which they are made up; just as the genuine performances of any art are what must be considered and observed in laying down the rules of that art. No solid precept can be formed in logic, except by examining arts and sciences, and attending to the method of reasoning used in them, and to the evidence that accompanies it. In proportion as they are cultivated, and no farther, logic may be improved. And what is true of the invention of logic, is true likewise of the study of it. It can be understood no farther, than the several sciences which it reviews and criticises are previously understood. Accordingly we find, that all the systems of logic which have not been compiled from a careful review and examination of the several sciences, consist more of ingenious subtleties than of useful precepts assisting to the mind in the various parts of knowledge. And when logic has been learned before the other sciences, the substantial parts of it have been scarce attended to, or made any use of, in the prosecution of them; nor so much as understood, but in as far as the mind was gradually opened, and brought to recollect them in its progress through the sciences.

"Logic is precisely the same to *philosophy* that works of criticism are to *poetry*. The rules of criticism are formed by an accurate scrutiny and examination of the best works of poetry. To one who had never read a poem, these rules would be obscure and useless; he could not comprehend them, far less would he be able to form a judgment of their justness, and of the reasons on which they are founded. If one peruses the best poetical performances, he will acquire some degree of taste, though he has never professedly studied the rules of criticism; and he will, at the same time, lay in materials, and obtain a stock of examples, which may render these rules intelligible to him, and enable him to judge whether they are just or not. And by afterwards studying these rules, he improves, refines, and corrects his taste, perceives the principles on which he has founded all his judgments, though he did not in the mean time think of them, and gains additional security against his judging wrong. This may illustrate what has been said of the place which logic ought to hold among the sciences. The observations made in it, both concerning the methods of invention and of probation, are founded on, and deduced from, the several sciences in which these methods are used. Neither the observations themselves, nor the reasons on which they are built, can be fully comprehended by one absolutely ignorant of these sciences. In studying the particular sciences, reason will spontaneously exert itself: if the proper and natural method of reasoning is used, the mind will, by the native force of its faculties, perceive the evidence, and be convinced by it, though it does not reflect *how* this comes to pass, nor explicitly consider according to what general rules the understanding is exerted. By afterwards studying these rules, one will be farther fitted for prosecuting the several sciences: the knowledge of the grounds and laws of evidence will give him the security of *reflection*, against employing wrong methods of proof and improper kinds of evidence, additional to that of *instinct* and *natural genius*. And thus logic will greatly contribute to improvement in knowledge; and more so, when it is used as a *review* of the method taken in the prosecution of science, of the foundations gone upon, and of the general rules that have been observed, than when it is applied as an *introduction* to the elements of science; for in the former case, its rules can be perfectly understood, sufficiently illustrated and put in practice as they are learned, which in the latter is quite impossible."

Having thus vindicated the new arrangement with respect to the place which it assigns to the study of logic, he proceeds to inquire in what order the other sciences should succeed each other. "Ethics (says he) or moral philosophy is founded as well as logic on pneumatics, and must therefore come after it. The constitution of man, and his several active powers, must be explained, before his business, his duty, and his happiness, can be discovered. Jurisprudence and politics, taking a more complex view of man than morals, by considering his various states, as well as his nature and powers, cannot, with any propriety, be introduced till morals have first been studied.

"It only remains then to determine whether natural philosophy or pneumatology ought, in the order of teaching, to have the preference. And many considerations seem to require that the former should be studied

died first. If it were not, pneumatology would be too far disjoined from the practical sciences founded on it; one of which, logic, ought, as we have seen, to be taught last of all. Besides, we ought always to begin with the easiest and most obvious subjects, and to proceed gradually to the most difficult; and in order to this, we ought to comply as much as possible with the natural openings and progress of the human mind. Now it is evident, that the mind receives first of all impressions and ideas of those sensible things with which it is surrounded. It is not till after it has exercised its faculties about them that it reflects on its own operations, or acquires perceptions of them. We are from our earliest infancy accustomed to observe external things, though often transiently and inattentively; they lie always in our view, they force themselves upon us, and we cannot avoid regarding them more or less. But we seldom attend to the operations of our minds in our earlier years; it is late before we acquire distinct notions of them, or can easily and readily make them the objects of our contemplation. Farther, external sensation, by which bodies are perceived, is a more palpable kind of evidence than internal, from which all our knowledge of spirits is derived; it strikes and affects us more. The philosophy of spirits, as well as that of bodies, is founded solely on experiments and observations; but in the latter it is much easier to make these than in the former: we can put *bodies* in any situation that we please, and observe at leisure their effects on one another: but the phenomena of the *mind* are of a less constant nature; we must catch them in an instant, and be content to glean them up, by observing their effects as they accidentally discover themselves in the several circumstances of life. The reasonings also by which conclusions are deduced concerning mind are of a more abstruse and difficult nature than those employed in the science of bodies; the ideas about which they are conversant are apter to be confounded with one another, and are with greater difficulty kept distinct. On all these accounts, natural philosophy must be to young minds easier than pneumatology, and consequently should be taught first."

For this long digression, if such it shall be deemed, we are persuaded that those who retain any attachment to the place where their minds were first imbued with the principles of science, will think no apology requisite, when they are informed, that the plan of education, which is here so ably defended, was about the same period adopted by both colleges in the university of Aberdeen; that the writer of this article had his own education in the King's college; and that in the prosperity of that college he still feels himself deeply interested. Let it be remembered, too, that the publication from which this extract has been made, furnishes a proof of professor Gerard's abilities, and of the estimation in which he was held by his colleagues at a very early period of life; and then surely the digression will not be thought impertinent.

He was now professor of moral philosophy and logic, and of these sciences alone: but though his *plan of education in the Marischal College* shews the order in which his lectures were arranged, we have not been able to learn on what foundation he built his system of ethics. As Hutcheson's Moral Philosophy was then much read and admired, it will not detract from Mr Gerard's merits to suppose, that, with his predecessor Mr Fordyce, he was an advocate for the *moral sense* of that author; for there are but three or four foundations on which a system of ethics can be raised; and it may be doubted whether there be one of them which is not as old as the age of Plato. It would indeed be ridiculous in any modern (A) to aim at giving a *new* foundation to moral virtue; for virtue must have been practised upon some steady principle from the earliest period of human society; and the most eminent professor will find sufficient room for the display of all his learning and ingenuity in illustrating the principle which his own judgment has led him to adopt.

Of this professor Gerard was fully sensible; and whilst he was conscientiously discharging his duty to his pupils, he neglected no opportunity of improving himself. He was member of a literary society at Aberdeen, of which the respectability will not be questioned, when it is known that it consisted of such men as the late Doctors Blackwell, Gregory, Reid and Campbell, with Dr Beattie, and many others of perhaps equal talents, though not known to the world as authors (B). This society met regularly during the winter, we believe once every fortnight; the members communicated their sentiments with the utmost freedom; every novel opinion was sure to be canvassed on all sides with impartiality; the understandings of the members were thus mutually whetted; and hence originated Reid's *Inquiry into the Human Mind*, Gregory's *Comparative View*, Gerard's *Essay on Genius*, Beattie's *Essay on Truth*, and Campbell's *Philosophy of Rhetoric*.

On the 5th of September 1759 Mr Gerard was ordained a minister of the Church of Scotland; on the 11th of June 1760, he was appointed professor of divinity in the Marischal college, and minister of the Grayfriars church in Aberdeen; and at the same time, as we suppose, created doctor in divinity.

On the 18th of June 1771 he resigned his Professorship in Marischal college, together with his church-living, and was preferred to the theological chair in the university of King's College, then become vacant by the death of professor Lumisden. In that station he continued, prosecuting his studies, beloved by his colleagues, and revered by his pupils, till his birth-day 1795; when, having just completed his 67th year, he died without a groan. His death was occasioned by a

---

(A) The friends of Mr Godwin, who affect to call his political justice the *new* philosophy, will, of course, think this a rash assertion; but were it worth while, it would be no very difficult task to produce, from the atheistical writers of ancient Greece, something similar even to his wildest paradoxes. Dr Gerard was too well acquainted with the subject, and too warm a friend to genuine virtue, to pretend to *novelty* in moral science.

(B) Such as Professor Thomas G[illegible]on, who read lectures in the King's College for 63 or 64 years, and whose learning was equalled only by his virtues.

Gerard.

schirrous tumour, which began to appear on his face in the year 1794, but without confining him to the house, or, except for a very few weeks, interrupting his usual pursuits. It impaired, however, his health, and gradually undermined his constitution. Of this he was very soon sensible; but he saw his dissolution approaching with the utmost composure and resignation, and preserved to all about him so much of that equanimity and placidness of temper which had marked the whole course of his life, that of him may truly be said,

> Multis illi multos annos precantibus
> Diri carcinomatis veneno contabuit,
> Nexibusque vitæ paulatim resolutis,
> E terris, meliora sperans, emigravit.

Were we to hazard an opinion of Dr Gerard's intellectual powers, from having attentively perused his works, we would say that he possessed great rectitude of judgment, rather than any remarkable vigour of mind; that he was capable, by intense study, of becoming master of almost any subject, though perhaps he had not the imagination requisite for making discoveries in science; and that his attainments were solid rather than brilliant. What he knew, he knew thoroughly; but to us, his knowledge seems to have been the reward of labour.

By one, to whom he was well known, and who himself stands high in the republic of letters*, we are assured that he had improved his memory to such a degree, that, in little more than an hour, he could get by heart any sermon of ordinary length; though far from availing himself of this talent, as many would have done, he composed with care all the sermons that he preached. In early life he made it a rule not to study after supper; and from that rule he never deviated, but amused himself after that time, either with the conversation of his family, or with any light reading that came in his way; and he was generally in bed by half past eleven. He seems not to have approved of early more than of late study; for though, for a few years, when as professor of philosophy he had various sciences to teach, he rose regularly, during winter, at five in the morning, he discontinued that practice as soon as he had it in his power, and did not enter upon serious study till after breakfast, generally about 10 o'clock. He was indeed very laborious through the day, and could with difficulty be persuaded to take any bodily exercise; but being remarkably temperate in eating and drinking, he enjoyed very good health, which was only occasionally interrupted by those stomach complaints, to which men of sedentary lives are often subject.

* Dr Beattie.

The fruits of this incessant study were, besides the lectures which he read to his different classes, 1*st*, *An Essay on Taste*, to which, in 1756, was adjudged the gold medal by the Philosophical Society of Edinburgh (See SOCIETIES, *Encycl.*), which had proposed *Taste* as the subject for a prize. Of this essay there has been a second and a third edition; of which the last, which was published in 1780, is considerably enlarged and improved. 2*d*, *Dissertations on the Genius and Evidences of Christianity*, published in 1766. 3*d*, *An Essay on Genius*, published in 1774. 4*th*, Two volumes of *Sermons*; of which the first was published in 1780, and the second in 1782. 5*th*, A part of his theological course, entitled *The Pastoral Care*, which was published in 1799 by his son Dr Gilbert Gerard, who succeeded him as professor of divinity in the King's college and university of Aberdeen. Besides these works Dr Gerard published many single sermons, which were preached on occasional subjects.

Of this amiable and respectable instructor of youth, we have been favoured with the following character, drawn by a man of talents and virtue†, who was first his pupil, and afterwards his friend; and though it made part of a funeral sermon, we believe that, by those who were most intimately acquainted with Dr Gerard, the panegyric which it contains will not be deemed extravagant.

† *The Rev. Skene Ogilvie, Old Aberdeen.*

" In domestic life, his conduct was amiable and exemplary. He possessed, in a high degree, that kindness of heart and affability of manner which interested him at all times in the happiness of his dependants, preserved good humour in his house, and endeared him to his family. He knew how to check improprieties without harshness, and when and how to indulge without impairing his authority. His natural good sense, steadiness and prudence, prevented him from being thrown into confusion by the adverse incidents of life; and enabled him, in pressing emergencies, to adopt wise measures, and to administer salutary counsel. His tender sympathy soothed the troubled hour of sorrow; his rational and friendly advice guided his family thro' the perplexities of life, and he feelingly rejoiced in all their innocent enjoyments. His attachments were not confined to his family or his relatives; he was susceptible of warm friendship. In selecting the objects of it he was cautious, always preferring those whose merits entitled them to confidence and regard. His attachment, slowly formed, was not to be shaken by every oblique insinuation, or by every idle report to the prejudice of his friend. Steady in his professions of regard, he was capable of considerable and disinterested exertions to serve those whom he really esteemed. To his judicious advice they had ready access; and his best efforts to promote their good they could always command. As a member of society, his house was ever the seat of hospitality, and his door was always open to the stranger. In entertaining his friends, he equally avoided the extravagance and ostentation which did not become his character or suit his fortune, and the rigid economy which marks the conduct of those who give with a reluctant and a sparing hand. He neither anxiously courted, nor affectedly shunned learned conversation. While he never obtruded upon company subjects which, by the display of superior knowledge or abilities, were calculated to gratify his own vanity at the expence of hurting others, he always studied, as far as propriety would admit, to adapt his conversation to the temper and inclinations of his associates. To please the young, and to promote their harmless festivity, was ever his delight; with cheerfulness he descended to their trivial amusements, and in his presence they felt no restraints but those which virtue and decency impose. Though he often left for a little studies in which he was keenly engaged, to enjoy the conversation of a friend, he never suffered his love of society, one of his strongest passions, to induce him to sacrifice any important literary pursuit, or to neglect any necessary business.

" As

"As a clergyman, the office which he held for several years in Marischal college rendered it his duty to be a daily preacher, and gave him a seat in the ecclesiastical courts. But the unavoidable labour of preparing prelections for his theological pupils, did not prevent his unremitting attention to his public exhibitions in the pulpit. These were marked by that distinctness of arrangement, that justness of reasoning, and that accuracy of composition, which effectually secured the approbation of the ablest judges; while by their plainness and simplicity, they failed not of promoting the edification of the meanest capacities. To the low arts of acquiring popularity he never stooped: But his prudence, his good sense, his exemplary conduct, and his ministerial diligence, established his respectability and usefulness, and procured him the full confidence and esteem of his colleagues. Possessing more than ordinary excellence, envy never led him to depreciate the merits of other preachers. Though one of the best of judges, he was always one of the most candid hearers. When by his translation to the university of King's college, he was released from the labour of constant preaching, far from shewing any aversion to discharge the most public ministerial duties, he was always obedient to presbyterial appointments; and while health and strength remained, willing to oblige his clerical friends by appearing in their pulpits. Nor in private life did he ever lose sight of the character of a clergyman. Having in a publication ably defended its respectability, in opposition to the scoffs and sneers and sophism of modern sceptics; he considered it as his honour, in his life and conversation to display its dignity and importance; and to shew that the gravity of a Christian pastor is perfectly consistent with the good breeding of a gentleman, and with the cheerfulness, affability, and ease of an agreeable companion.

"As a man of letters, his attainments were far above those at which the generality of students arrive. In his literary pursuits, he had all the advantages of a judgment uncommonly clear and distinct, aided, from his earliest years, by the most indefatigable and persevering study. The well-earned reputation with which, before he was promoted to the theological chair, he taught in Marischal college different sciences, incontestibly proves that his powers, not confined to one subject, justly entitled him to eminence in several branches of literature. His publications, several of which have been translated into other languages, promise fair to extend his fame, and to hand it down to generations yet unborn; and his unremitting labours promised still a farther contribution to the general stock of learning.

"As a professor of divinity, he will be long and gratefully remembered by his numerous pupils. This was his peculiar department, and in this he shone. Possessing large stores of theological knowledge, he was judicious in selecting his subjects, happy and successful in his manner of communicating instruction. He had the merit of introducing a new, and in many respects a better plan of theological education, than those on which it had been formerly conducted. Liberal, but not loose, in his sentiments, his great aim was, not to impose by his authority upon his pupils any favourite system of opinions; but to impress them with a sense of the importance of the ministerial office, to teach them the proper manner of discharging all its duties, and to enable them, by the knowledge of Scripture, to form a just and impartial judgment on controverted subjects. Solicitous for their improvement, he was ever ready to encourage rising merit by his warmest approbation; and reluctant to damp even unsuccessful efforts of genius by deserved censure. Having a constant eye to what is practically useful, rather than to unedifying speculation, he enjoined no duty which he was unwilling to exemplify in his own conduct. Hence that strict regard to the ministerial character which he uniformly displayed, and hence his uncommon punctuality in attending the public ordinances of religion."

GERARDSTOWN, a neat little town, situated in Berkely co. Virginia, containing about 30 or 40 houses; 10 miles from Martinsburg, and 254 from Philadelphia.—*Morse.*

GERMAN, a township in Fayette co. Pennsylvania.—*ib.*

German Flats, the chief township of Herkemer co. taken from that of Montgomery, in New-York. By the census of 1790, it contained 1307 inhabitants, including 20 slaves; by the State census of 1796, 4194 inhabitants, of whom 684 are electors. It lies on the south side of Mohawk river, opposite Herkemer. It is 24 miles E. of Whitestown, and 60 miles west of Schenectady.—*ib.*

GERMANTOWN, (N. Y.) in Columbia co. containing 516 inhabitants. In 1796, it had 75 qualified voters.—*ib.*

Germantown, in Philadelphia co. Pennsylvania, is situated 7 miles north of Philadelphia city, and was esteemed the second town in the country, until several inland towns eclipsed it, by superior establishments and number of inhabitants. It is a corporation, consisting chiefly of High and Low Dutch, and contains about 250 houses, chiefly of stone, some of which are large, elegant and commodious; built chiefly on one street, about two miles in length. The public buildings are a German Calvinist and Lutheran church, a Friend's meeting-house, and an academy. Knit stockings, of cotton, thread and worsted, are manufactured here by individuals to a considerable extent, and of an excellent quality. It is an ancient town, pleasantly situated, and by its vicinity to the metropolis, well adapted for manufactures. Here is the principal congregation of the Mennonists, and the mother of that sect in America. They derive their name from Menno Simon, a learned man of Witmars, in Germany, one of the reformers, born in 1505. Some of his followers came into Pennsylvania, from New-York, in 1692. There are about 4000 of them in the State. They do not, like the Tunkers, believe in general salvation; yet, like them, they will neither swear nor fight, nor bear any civil office, nor go to law, nor take interest for money, though many break that rule. They use great plainness in their dress, &c. and practise many of the rites of the primitive Christian church. This town is also rendered famous, by the battle fought in it, on the 4th of Oct. 1777.—*ib.*

Germantown, a post-town and the capital of Stokes co. N. Carolina. It is situated near the Town Fork of Dan river, and contains a court-house, gaol, and about 30 houses. It is 528 miles S. W. by S. of Philadelphia.—*ib.*

Germantown, the chief town of Hyde co. in Newbern district, N. Carolina.—*ib.*

GERMANY, a township in York co. Pennsylvania.—*ib.*

GERMINATION, among botanists, is a very interesting subject on which the late discoveries in chemistry have thrown much light since the article Germination was published in the *Encyclopædia*. In the year 1793, Mr Humboldt discovered that simple metallic substances are unfavourable to the germination of plants, and that metallic oxyds favour it in proportion to their degree of oxydation. This discovery induced him to search for a substance with which oxygen might be so weakly combined as to be easily separated, and he made choice of oxygenated muriatic acid gas mixed with water. Cresses (*lepidium sativum*) in the oxygenated muriatic acid shewed germs at the end of six hours, and in common water at the end of 32 hours. The action of the first fluid on the vegetable fibres is announced by an enormous quantity of air bubbles which cover the seeds, a phenomenon not exhibited by water till at the end of from 30 to 45 minutes. These experiments announced in Humboldt's *Flora Subterranea Fribergensis*, and in his Aphorisms on the chemical physiology of Plants, have been repeated by others (A). They were made at a temperature of from 12 to 15 Reaumur. In the summer of 1796, Humboldt began a new series of experiments, and found that by joining the stimulus of caloric to that of oxygen he was enabled still more to accelerate the progress of vegetation. He took the seeds of garden cresses (*lepidium sativum*), peas, (*pisum sativum*), French beans (*phaseolus vulgaris*), garden lettuce (*lactuca sativa*), mignonette (*reseda odorata*); equal quantities of which were thrown into pure water and the oxygenated muriatic acid at a temperature of 88° F. Cresses exhibited germs in three hours in the oxygenated muriatic acid, while none were seen in water till the end of 26 hours. In the muriatic, nitric (B), or sulphuric acid, pure or mixed with water, there was no germ at all: the oxygen seemed there to be too intimately united with bases of azot or sulphur, to be disengaged by the affinities presented by the fibres of the vegetable. The author announces, that his discoveries may one day be of great benefit in the cultivation of plants. His experiments have been repeated with great industry and zeal by several distinguished philosophers. Professor Pohl at Dresden caused to germinate in oxygenated muriatic acid the seed of a new kind of *euphorbia* taken from Bocconi's collection of dried plants, 110 or 120 years old. Jacquin and Vander Schott at Vienna threw into oxygenated muriatic acid all the old seeds which had been kept 20 or 30 years at the botanical garden, every attempt to produce vegetation in which had been fruitless, and the greater part of them were stimulated with success. Even the hardest seeds yielded to this agent. Among those which germinated were the yellow bonduc or nickar tree (*guilandina bonduc*), the pigeon cytisus or pigeon pea (*cytisus cajan*), the *dodonæa angustifolia*, the climbing mimosa (*mimosa scandens*), and new kinds of the *homæa*.—There are now shewn at Vienna very valuable plants which are entirely owing to the oxygenated muriatic acid, and which are at present from five to eight inches in height. Humboldt caused to germinate the *clusia rosea*, the seeds of which had been brought from the Bahama islands by Boose, and which before had resisted every effort to make them vegetate. For this purpose he employed a new process, which seems likely to be much easier for gardeners who have not an opportunity of procuring oxygenated muriatic acid: He formed a paste by mixing the seeds with the black oxyd of manganese, and then poured over it the muriatic acid diluted with water. Three cubic inches of water were mixed with half a cubic inch of the muriatic acid. The vessel which contains this mixture must be covered, but not closely shut; else it might readily burst. At the temperature of 95° the muriatic acid becomes strongly oxydated; the oxygenated muriatic gas which is disengaged passes through the seeds; and it is during this passage that irritation of the vegetable fibres takes place.—*Philosophical Magazine.*

GERRY, a township in Worcester co. Massachusetts. It was incorporated in 1786 and contains 14,000 acres of land, on which are 740 inhabitants. It is 30 miles N. W. of Worcester, and 65 N. W. by W. of Boston. —*Morse.*

GESCHE el Aube, or Gir Gir, a species of grass growing plentifully near *Ras el Feel* on the borders of Abyssinia. It begins, says Mr Bruce, to shoot in the end of April, when it first feels the humidity of the air. It advances then speedily to its full height, which is about 3 feet 4 inches. It is ripe in the beginning of May, and decays, if not destroyed by fire, very soon afterwards.

The leaf is long, pointed, narrow, and of a feeble texture. The stock from which it shoots produces leaves in great abundance, which soon turn yellow and fall to the ground. The goats, the only cattle these miserable people have, are very fond of it, and for it abandon all other food while it is within their reach. On the leaves of some plants our author saw a very small glutinous juice, like to what we see upon the leaves of the lime or the plane, but in much less quantity; this is of the taste of sugar.

From the root of the branch arises a number of stalks, sometimes two, but never, as far as he had seen, more than three. The flower and seed are defended by a wonderful perfection and quantity of small parts. The head when in its maturity is of a purplish brown. This

(A) See Uslar's Fragments of Phytology, Plenck's Physiology, Villdenow's Dendrology, and *Dictionaire de Physique* par Gehler.

(B) The nitric acid, however, diluted with a great deal of water, accelerates germination also, according to the experiments of Candolle, a young naturalist, who has applied with great success to vegetable physiology. This phenomena is the more interesting, as chemistry affords other analogies of the oxygenated muriatic acid and the nitric acid. Professor Pfass at Kiel, by pursuing Humboldt's experiments, has found that frogs suffocated in oxygenated muriatic acid gas increase in irritability, while those which perish in carbonic acid gas are less sensible of galvanism.

Gettysburgh ‖ Gheyssiquas.

This species of grass was one of the acquisitions of our author's travels. It was not before known in Europe, nor when he published his book had the seed produced a plant any where but in the garden of the French king.

GETTYSBURGH, a small town in York co. Pennsylvania, situated at the head of Rock Creek, one of the head waters of the Monococy, and contains about 30 houses. It is 9 miles north of the Maryland line. 8 miles from Millerstown, 15 from Abbotstown, 36 from Williamsport in Maryland, and 118 W. by S. of Philadelphia.—*Morse.*

GHEYSSIQUAS, a nation of Hottentots which inhabits a district of South Africa bordering on the country of Caffraria. M. Vaillant visited a horde of this people at no great distance from Orange river, as he was returning from his last African excursion to the Cape, and was shewn by them a chain of mountains to the east which extending to a distance was lost in the north, and which, inhabited by their principal tribes, separated them from the Caffres, or at least from the Briquas and Bremas, whom they consider as tribes of Caffres.

With respect to such characteristics as are not original and derived from nature, as the form of their dress, weapons, instruments of music, fondness for hunting and dancing and the like, the Gheyssiquas do not differ from the surrounding nations, except in having adopted a particular colour for their ornaments. All the ornaments of the Gheyssiquas are white, and composed of the bones of a sheep's leg or foot, to which they give a dazzling whiteness by processes peculiar to themselves. Thus, as they fabricate their own necklaces and other articles of luxury, and have no occasion to purchase the materials, they have no dependance on the colonies with respect to trade, except for a few necessary articles which they want in common with other savages. Accordingly this nation is less known and less visited than any other.

The women are well made, lively, and always ready to laugh or dance: yet, with all the gaiety of their disposition, they have the reservedness of manners to which polished nations give the names of modesty and decorum, and which, in so warm a climate and with such ardent constitutions, appears to be a virtue of no easy attainment.

Our author says that he no where met with a nation so truly generous. Though he had nothing to give in exchange, yet during two days that he staid with them, he had bowls of milk brought to him as presents, night and morning, from every hut. The chief even obliged him to accept a lamb; and though our traveller's attendants were not destitute of provisions, he would give them also several sheep with which to regale themselves; a degree of generosity of which a proper estimate can be formed only by those who know something of savage manners and savage penury.

The practice of semi-castration prevails among the Gheyssiquas, and among them only of all the Hottentot tribes; and it prevails in all their hordes without exception. Our author convinced himself of this fact by his own eyes; for the men were so complaisant, that, if he had chosen, he might have inspected the whole horde. Many travellers have written upon the subject of this whimsical operation; but they do not agree either as to its origin, the motives that lead to its invention, or the nations by whom it is practised. Kolben, who says that it commonly consists in the extraction of the left testicle, represents it as a religious ceremony, a general and sacred law, with all the Hottentots indiscriminately; but this is unquestionably false. (See HOTTENTOTS, *Encycl.*) Others attribute it to the desire of the Gheyssiquas to render themselves more fleet in running, an effect which it surely is not calculated to produce; and some have said that its intention is to prevent the too abundant propagation of the species. Yet Kolben, though he seems inclined to this last opinion, affirms, that twins are not the less common on account of the operation. According to those whom M Vaillant questioned on the subject, it is merely a mark of distinction which their ancestors, being at war with the neighbouring nations, invented for the purpose of knowing one another; but, as he himself admits, this is a very improbable account of the matter, as they would surely have adopted, like the Loangoes, Pomboes, and Cormantins, marks of distinction more easily discerned. Be this as it may, the operation among the Gheyssiquas is performed by the father, commonly at the birth of the child, though sometimes not till he has completed his third year.

Gheyssiquas ‖ Ghirgong.

GHIRGONG, the capital of *Asam* in Hindostan is, according to Mr Pennant, situated in latitude 26° 30′ north. He does not state its longitude. It has four gates, and the city is encompassed with a bound hedge of bamboos. The Rajah's palace is surrounded by a causey, planted on each side with a close hedge of bamboos, which serves instead of a wall. On the outside there is a ditch, which is always full of water. The Rajah's seat is adorned with lattice work and carving. Within and without have been placed plates of brass, so well polished, that when the rays of the sun strike upon them they shine like mirrors. It is an ascertained fact, that 3000 carpenters and 12,000 labourers were constantly employed in this work during two years before it was finished. *Pennant's View of Hindostan.*

The Asiatic Researches speak much of the wealth of Asam, and of the plenty and excellency of its natural productions, and that it abounds in all metals but tin. Gold is found in every part of the country by washing the sand of the rivers, and is one of the sources of revenue; 12,000, some say 20,000 people, are employed in that work, each of whom has from the Rajah a certain wages Its gum lac is excellent, and it is very productive of silk.

Among the fruits which this country produces are mangoes, plantains, jacks, oranges, citrons, limes, pine apples, and puniala, a species of tamarind, which has such an excellent flavour, that every person who tastes it prefers it to the plum. There are also cocoa-nut trees, pepper vines, and the areca trees. The sugar cane excels in softness and sweetness, and is of three colours, red, black and white. There is ginger free from fibres, and betel vines. The strength of vegetation and fertility of the soil are such, that whatever seed is sown or slips planted they always thrive. The environs of Ghirgong furnish small apricots, yams, and pomegranates; but as these articles are wild, and not amilted by cultivation and engraftment, they are very indifferent. The principal crop in this country consists in rice and lentiles. Wheat and barley are never sown; lignum

aloes

aloes is also a production of this country. The silks are excellent, and resemble those of China, but they manufacture very few more than are required for use. They are successful in embroidering with flowers and in weaving velvet.—One of their great forests is inhabited by abundance of elephants: 6 or 700 may be taken in a year, but they are neglected by the natives, who have neither horses, camels nor asses, such as are brought from other countries.

According to our author, "the people of Asam are a base unprincipled nation, and have no fixed religion. They follow no rule but that of their own inclination, and make their own vicious minds the test of the propriety of their actions. They do not adopt any mode of worship practised either by heathens or Mahomedans, nor do they concur with any of the known sects which prevail among mankind; unlike the pagans of Hindostan, they do not reject victuals which have been dressed by Moslems, and they abstain from no flesh except human. They even eat animals that have died a natural death."

On this passage, one of the ablest of our literary journalists observes, that in justice to the people of Asam, we must remark, that the above account, extracted from the memoirs of Mir Jumla's expedition into that country, was composed by a rigid Mahomedan, at the court of that fanatical tyrant Aurengzebe. The author and his master saw, in the Asamese, only idolaters; and, in idolaters, the meanest of mankind. Their diet, though less restricted than that of the Hindoos of Bengal, is by no means promiscuous; and their religion does not in any way differ from that of Hindostan, as might easily be proved by their coins, inscribed with the names of Hindoo deities.

GIBBON (Edward Esq.), the celebrated historian of the Decline and Fall of the Roman Empire, was born at Putney in the county of Surry on the 27th of April 1737. He was the first child of the marriage of Edward Gibbon, Esq; and Judith Porten, the youngest daughter of a merchant of London.

The family of Gibbon appears to be ancient and honourable; and our author delights to trace his pedigree from John Gibbon architect to King Edward III. who possessed lands in the hundred and parish of Rolvenden, in the district which is now called the *Weald* of Kent. In that district the elder branch of the family still adheres to its native soil, without much increase or diminution of property; but the fortunes of the younger branch, from which sprung the subject of this memoir, were fluctuating. It is not, however, with his family, but with himself, that we are concerned.

So feeble was his constitution, and so precarious his life during his childish years, that at the baptism of each of his brothers (and they were five in number) his father's prudence successively repeated the name of Edward, that, in case of the death of the eldest son, this patronymic appellation might still be perpetuated in the family. His brothers and a sister were all snatched away in their infancy; and, in terms of affectionate gratitude, he attributes his own preservation to the more than maternal care of a maiden aunt, his mother's eldest sister. "Many anxious and solitary days (says he) did that dear and excellent woman consume in the patient trial of every mode of relief and amusement. Many wakeful nights did she sit by my bed side in trembling expectation that each hour would be my last. Suffice it to say, that while every practitioner from Sloane and Ward to the Chevalier Taylor was successively summoned to torture or relieve me, the care of my mind was too frequently neglected for that of my health. Compassion always suggested an excuse for the indulgence of the master, or the idleness of the pupil; and the chain of my education was broken as often as I was called from the school of learning to the bed of sickness."

His education seems indeed to have been far from systematical. At the age of seven he was delivered into the hands of Mr John Kirkby, who exercised about eighteen months the office of his domestic tutor, and of whom he writes in terms of respect. This man had been an indigent curate in Cumberland, and when forced by distress to leave his native country, he was introduced by his learning and his virtue to the family of Mr Gibbon, from whom he might have found at least a temporary shelter, had not an act of indiscretion again driven him into the world. One day reading prayers in the parish church, he most unluckily forgot the name of King George; and his patron, a loyal subject, dismissed him with some reluctance and a decent reward. As our author describes his ancestors as hereditary Tories, and some of them as Jacobites, we think it not improbable that Mr Kirkby may have been accustomed to omit the name of the King when reading prayers in the family; for otherwise he would have pronounced it mechanically in the church.

Be this as it may, our author, upon the dismission of his tutor, was sent to Kingston upon Thames, to a school of seventy boys kept by Dr Woodeson and his assistants. He does not represent himself either as happy or as having made great progress at that school. The want of strength and activity disqualified him for the sports of the field; his companions reviled him for the sins of his Tory ancestors; and his studies were frequently interrupted by sickness. After a real or nominal residence of near two years at Kingston, he was finally recalled (Dec. 1747) by the death of his mother. By this time he was well acquainted with Pope's Homer, the Arabian Nights Entertainments, Dryden's Virgil, and a translation of Ovid's Metamorphoses; and the entertainment which he received from these books gave him a taste for desultory reading.

After living a year with his maternal aunt, during which period he read many books on religious subjects too deep for the comprehension of a boy, he was in January 1749 entered in Westminster school, of which Dr John Nicoll was at that time head master. "There (says he) in the space of two years, interrupted by danger and debility, I painfully climbed into the third form; and my riper age was left to acquire the beauties of the Latin, and the rudiments of the Greek tongue. Instead of audaciously mingling in the sports, the quarrels, and the connections of our little world, I was still cherished at home under the maternal wing of my aunt, who now lived in College street; and my removal from Westminster long preceded the approach of manhood."

He was first carried to Bath for the recovery of his health; then to Winchester, where he lived in the house of a physician, then to Bath again, where he read with a clergyman some odes of Horace and some episodes of Virgil; after which an unsuccessful trial was made to renew his attendance at Westminster school. "It might now be

Gibbon.

be apprehended (says he) that I should continue for life an illiterate cripple; but as I approached my sixteenth year, nature displayed in my favour her mysterious energies: my constitution was fortified and fixed; and my disorders, instead of growing with my growth, and strengthening with my strength, most wonderfully vanished. In consequence of this he was carried to Oxford; and before he had accomplished his fifteenth year, was, on April 3, 1752, matriculated a gentleman commoner of Magdalen college.

For the honour of that celebrated university, we would fain hope that the account which Mr Gibbon gives of Magdalen college is greatly exaggerated. He represents his tutors as wholly regardless of his morals or his studies. Speaking of the first and best of them, for he had two, he says, "No plan of study was recommended for my use; no exercises were prescribed for his inspection; and, at the most precious season of youth, whole days and weeks were suffered to elapse without labour or amusement, without advice or account." We shall make no other remark on this passage than that from gentlemen, who must have been contemporary with Mr Gibbon at Magdalen, we have received different accounts of the college; and it is surely a very singular circumstance, that at this period of idleness, our author should have become enamoured of Sir John Marsham's *Canon Chronicus*, and have conceived the idea of writing an *Essay on the age of Sesostris*. Such, however, was the case. Not only was the essay planned, but part of it was written; and though he never finished it, he declares, that his solution of some difficulties in chronology was not devoid of ingenuity; but he goes on to vilify Oxford. "It might at least be expected (says he), that an ecclesiastical school should inculcate the orthodox principles of religion. But our venerable mother had contrived to unite the opposite extremes of bigotry and indifference: an heretic, or unbeliever, was a monster in her eyes; but she was *always*, or *often*, or *sometimes* (A), remiss in the spiritual education of her own children. Without a single lecture, either public or private, either Christian or Protestant, without any academical subscription, without any Episcopal confirmation, I was left by the dim light of my catechism to grope my way to the chapel and communion table, where I was admitted, without a question, how far, or by what means, I might be qualified to receive the sacrament. Such almost incredible neglect was productive of the worst mischiefs. From my childhood I had been fond of religious disputation; nor had the elastic spring been totally broken by the weight of the atmosphere of Oxford. The blind activity of idleness urged me to advance without armour into the dangerous mazes of controversy; and, at the age of sixteen, I bewildered myself in the errors of the church of Rome."

Thus anxious is our author to account for his reconciliation to the Romish church by the negligence of the tutors of his college. This event took place on the 8th of June 1753, when, at the feet of a priest in London, he solemnly, though privately, abjured the errors of heresy. An elaborate controversial epistle, approved by his director, and addressed to his father, announced and justified the step he had taken; and the old gentleman, in the first sally of passion, divulging the secret, the gates of Magdalen college were shut against the convert. It was necessary therefore to form a new plan of education; and our young Catholic, by the advice of Mr Elliot (afterwards Lord Elliot), was settled, on the 30th of June, under the roof and tuition of Mr Pavilliard, a Calvinist minister at Lausanne in Switzerland.

Gibbon.

He represents his situation there as at first extremely uncomfortable. He could not avoid contrasting a small chamber, ill contrived and ill furnished, with his elegant apartment in Magdalen college; and M. Pavilliard being entrusted with the management of his expences, he felt himself degraded from the rank of gentleman commoner to that of a school-boy. He began, however, gradually to be reconciled to his fate; and his love of reading returned, which, he says, had been chilled by the air of Oxford. He rapidly acquired the French language; and of his tutor, he says, "My obligations to the lessons of Mr Pavilliard gratitude will not suffer me to forget. He was endued with a clear head and a warm heart; his innate benevolence had assuaged the spirit of the church; he was rational, because he was moderate: in the course of his studies he had acquired a just though superficial knowledge of most branches of literature; by long practice he was skilled in the arts of teaching; and he laboured with assiduous patience to know the character, gain the affection, and open the mind of his English pupil."

Under the tuition of this amiable preceptor he describes his progress in the French and Latin classics, in history, geography, logic and metaphysics, as uncommonly rapid; and he allows to the same man a handsome share of the honour of reclaiming him from the errors of popery. The various discriminating articles of the Romish creed disappeared like a dream; and after a full conviction, on Christmas day 1754, he received the sacrament in the church of Lausanne. Thus had our author communicated with three different societies of Christians before the completion of his eighteenth year; and as such changes from church to church are always dangerous, we need not wonder, that, in a mind so ill furnished as Mr Gibbon's then was for theological investigations, they paved the way for his last change to Deism. At present, however, he suspended his religious inquiries, acquiescing (as he says) with implicit belief in the tenets and mysteries which are adopted by the general consent of Catholics and Protestants.

He continued to prosecute his studies with ardour. Under Mr Pavilliard he learned the Greek alphabet, the grammar, and the pronunciation of the language according to the French accent, and soon made himself master of the works of Homer, Herodotus, and Xenophon. During two winters he attended the private lectures of M. de Traytorrens, who explained the elements of algebra and geometry as far as the conic sections of the Marquis de l'Hôpital; but in mathematics he was content (he says) to receive the passive impression of his professor's lectures, without any active exercise of his own powers. In the writings of Grotius and Puffendorf he studied the duties of a man, the rights of a citizen,

(A) Surely *always* and *sometimes* are words of very different import: why are they used then, in this sentence as synonymous?

Gibbon. Gibbon.

tizen, the theory of justice, and the laws of peace and war, which have had some influence on the practice of modern Europe. "Locke's treatise on government, (says he) instructed me in whig principles, which are founded rather in reason than experience; but my delight was in the frequent perusal of Montesquieu, whose energy of style and boldness of hypothesis were powerful to awaken and stimulate the genius of the age."

We have been thus minute in our account of Mr Gibbon's studies, because it furnishes perhaps the most useful lesson which can be drawn from the whole history of his life. His education had been rendered irregular, and had been often interrupted by ill-health and a feeble constitution; but as soon as he was able, and had an opportunity, he applied with ardour to the cultivation of letters, and his works bear witness that his labour was crowned with success. "This part of his story therefore (to use the words of Johnson) well deserves to be remembered. It may afford useful admonition and powerful encouragement to men whose abilities have been made, for a time, useless, and who, having lost one part of life in idleness, are tempted to throw away the remainder in despair."

In the year 1757 Voltaire arrived at Lausanne, and our young student's desire to see the man who was at once a poet, an historian, and, as he deemed himself, the prince of philosophers, was ardent, and easily gratified. He was received by the vain and arrogant Frenchman with civility as an English youth, but could not boast of any peculiar notice or distinction. "The highest gratification (says he) which I received from Voltaire's residence at Lausanne, was the uncommon circumstance of hearing a great poet declaim his own productions on the stage. His declamation was fashioned to the pomp and cadence of the old stage; and he expressed the enthusiasm of poetry rather than the feelings of Nature."

About this time Mr Gibbon became enamoured of Mademoiselle Susan Curchod, the daughter of the minister of Crassy, in the mountains which separate the Pays de Vaud from the county of Burgundy. In terms of rapture he describes this lady as possessed of every accomplishment which could adorn her sex. She listened to the voice of truth and passion; her parents honourably encouraged the connection; and our author indulged in the dream of felicity: but on his return to England, he discovered that his father would not hear of this strange connection, and that without his consent he was destitute and helpless. "After a painful struggle (says he) I yielded to my fate. I sighed as a lover, I obeyed as a son, and my wound was insensibly healed by time, absence, and the habits of a new life." The lady consoled herself by giving her hand to M. Neckar, then a rich banker of Paris, afterwards the minister, and at last one of the destroyers of the French monarchy.

In the spring of the year 1758 our author was recalled to England. On his arrival in London he hastened to the house of his aunt, Mrs Porten, who had been the guardian of his tender years; for though his father was in town awaiting his arrival, he knew not how he should be received by a parent who had parted with him in anger, and given him a stepmother in his absence. His reception was more agreeable than he expected. His father received him as a man and a friend; and the manners of Mrs Gibbon were such, that, after some reserve on his side, she and he easily adopted the tender names and genuine characters of mother and son; and, by the indulgence of these parents, he was left at liberty to consult his own taste or reason in the choice of place, of company, and of amusements. In London he had few acquaintances, and hardly any friends; and being accustomed to a very small society at Lausanne, he preferred the retirement of the country to the bustle of that over-grown metropolis, where he found hardly any entertainment but in the theatres.

Before he left Lausanne he had begun a work on the study of ancient literature, which was suggested by the desire of justifying and praising the object of a favourite pursuit. "In France (says he), to which my ideas were confined, the learning and language of Greece and Rome were neglected by a philosophic age. The guardian of those studies, the Academy of Inscriptions, was degraded to the lowest rank among the three royal societies of Paris: the new appellation of *Erudits* was contemptuously applied to the successors of Lipsius and Casaubon; and I was provoked to hear*, that the exercise of the memory, their sole merit, had been superseded by the nobler faculties of the imagination and the judgment. I was ambitious of proving by my own example, as well as by my precepts, that all the faculties of the mind may be exercised and displayed by the study of ancient literature." This laudable ambition continued; and in his father's house at Beriton in Hampshire he finished his *Essai sur l'Etude de la Literature;* which, after being revised by Mallet the poet and Dr Maty of the British museum, was, in 1761, published in a small 12mo volume.

* See *Le Discours Preliminaire par D'Alembert à l'Encyclopedie.*

The subjects of taste, criticism, and philosophy, which in this work came under our young author's consideration, could hardly promise much novelty of remark. Some former observations, however, he appears to have placed in a new and pleasing point of view; advancing, moreover, some ingenious conjectures, and displaying no inconsiderable erudition. Yet, by his own account, he was at this time almost a stranger to the writers of Greece; and when he quotes them, it is probable that the quotations are given at second hand. To this essay was prefixed a dedication to his father in the English language, which exhibits the author himself in a very amiable light; but if his reputation had depended solely upon this youthful attempt, the name of Gibbon would have been lost in oblivion. Yet he seems, even in his riper years, to have been delighted with it himself, and to have considered its merits as equal to those of his later productions; but Milton, it is said, preferred the Paradise Regained to the Paradise Lost.

Before the publication of this essay, the author, at his own desire, had been appointed a captain in the South-Hampshire militia, in which he served upwards of two years. At first, the company of rustic and illiterate officers, and the bustle of a military life were extremely disagreeable to him, as they interrupted his studies; but he admits, that his military services, his bloodless and inglorious campaigns, as he calls them, were, on the whole, beneficial, as they brought him acquainted with English manners, English parties, and English principles, to which his foreign education and reserved temper had hitherto kept him an entire stranger. In the camp and in quarters he had even found leisure, after the first seven or eight months of his service, to read a great deal of Greek, Gibbon. Greek, and to plan different historical works, to the composition of which he seems to have thought that he was born with an innate propensity. He always talks of himself as a philosopher; but surely a more unphilosophical persuasion than this has seldom been admitted.

At the end of the war he went again abroad, and reached Paris on the 28th of January 1763, only 36 days after the disbanding of the militia, in which he had borne the commission of a captain. In that metropolis he staid not long. He visited palaces, churches, gardens, and theatres, and was introduced to D'Alembert and Diderot, then considered as at the head of French science. From Paris he proceeded to Switzerland, and once more took up his residence at his favourite Lausanne. Voltaire's impieties had forced him from that town to his own castle at Ferney, where our author once visited him, without (he says) courting his more intimate acquaintance.

The society in which Mr Gibbon most delighted during his second residence at Lausanne was a very singular one. "It consisted of fifteen or twenty unmarried ladies of genteel families; the eldest perhaps about twenty, all agreeable, several handsome, and two or three of exquisite beauty. At each other's houses they assembled almost every day, without the controul, or even the presence of a mother or an aunt; they were trusted to their own prudence, among a crowd of young men of every nation in Europe. They laughed, they sung, they danced, they played at cards, they acted comedies; but in the midst of this careless gaiety, they respected themselves, and were respected by the men; the invisible line between liberty and licentiousness was never transgressed by a gesture, a word or a look, and their virgin chastity was never sullied by the breath of scandal or suspicion."

We readily agree with our author that this singular institution was expressive of the innocent simplicity of Swiss manners; and we only regret that he had not the same respect for the ladies of his own country as for those frolic females of Switzerland. He would not, in that case, have stained some of his most brilliant pages with obscene ribaldry.

We shall not follow him in his ramble through Italy, or repeat his remarks on the towns which he visited. It is sufficient, in such a sketch as this, to inform our readers, that it was at Rome on the 15th of October 1764, as he sat musing amidst the ruins of the Capitol, that the idea of his great work first started into his mind. But his original plan was circumscribed to the decay of the city rather than of the empire.

From carrying even this contracted plan into execution he was for some years diverted. On the 25th of June 1765 he arrived from Italy at his father's house in Hampshire, and found that he had filial duties to perform which interrupted his studies and disturbed his quiet. His father had involved himself in difficulties, from which he could be extricated only by selling or mortgaging part of his estate; and to such sale or mortgage our author cheerfully consented. He regrets on this occasion that he had not "embraced the lucrative pursuits of the law or of trade, the chances of civil office or India adventure, or even the fat slumbers of the church;" and it is to be hoped that, when he thought even of *slumbering* in the church, he had still some faith in revealed religion. He wasted some time in planning a history of the revolutions of Switzerland, and even wrote part of it in the French language, which, by the advice of friends, he however suppressed. We next find him engaged with a friend in a journal entitled *Memoires Literaires de la Grand Bretagne*, of which two volumes for the years 1767 and 1768 were published, and a third almost completed, when his friend, a native of Switzerland, was engaged, through his interest, as travelling governor to Sir Richard Worsley, and the Journal was of course, abandoned. He then entered the lists with Warburton; whose interpretation of the sixth book of the Æneid he attacked with great petulance and with much success. The bishop of Glocester was by this time in a state of great mental decay, which was peculiarly unfortunate for our author; for had his Lordship enjoyed his pristine vigour, he would probably have given Mr Gibbon such a chastisement as might have made him more modest afterwards when writing the history of the Decline and Fall of the Roman Empire.

To that great work he now sat down seriously; and the history which he gives of his preparatory studies sufficiently accounts for the inaccuracy of his quotations. Through the darkness of the middle ages he explored his way in the annals and antiquities of Italy by the learned Muratori and other moderns; and seems to acknowledge that, from the beginning to the end of his work, he frequently contented himself with authorities furnished at second hand.

At last, in 1776, the first volume of his history was published by Cadell the bookseller and Strahan the printer; and the success of it far surpassed his expectation. The encomiums lavished on it by Dr Robertson and Mr Hume in letters to the author, and the fulsome compliments which those three eminent historians paid to each other, are melancholy specimens of lettered littleness and vanity. The second and third volumes appeared in 1781; the fourth, fifth and sixth in 1787; and Mr Gibbon's fame was established as a historian. The work was admired both by natives and by foreigners, and translated into several of the languages of Europe. Dr Zimmerman represents the author as excelling perhaps Hume and Robertson, who were historians of the first rank. "All the dignity (he adds), all the charms of historic style, are united in Gibbon: his periods are melody itself, and all his thoughts have nerve and vigour." This praise, however, must not be admitted without exception. Few writers, indeed, were possessed of such popular talents as our historian. The acuteness of his penetration, and the fertility of his genius, have been seldom equalled, and scarcely ever surpassed. He seizes, with singular felicity, on all the most interesting facts and situations, and these he embellishes with the utmost luxuriance of fancy and elegance of style. His periods are full and harmonious; his language is always well chosen, and is frequently distinguished by a new and peculiarly happy adaptation. His epithets, too, are in general beautiful and happy; but he is rather too fond of them. The uniform stateliness of his diction sometimes imparts to his narrative a degree of obscurity, unless he descends to the miserable expedient of a note, to explain the minuter circumstances. His style, on the whole, is much too artificial; and this gives a degree of monotony to his periods, which

which extends, we had almost said, to the turn of his thoughts.

A more serious objection is his attack upon Christianity; the loose and disrespectful manner in which he mentions many points of morality regarded as important on the principles of natural religion; and the indecent allusions and expressions which too often occur in the work.

An attack upon Christianity is not censurable merely as such; it may proceed from the purest and most virtuous motives: but, in that case, the attack will never be carried on in an insidious manner, and with improper weapons; and Christianity itself, so far from dreading, will invite every mode of fair and candid discussion. Our historian, it must be confessed, often makes, when he cannot readily find, an opportunity to insult the Christian religion. Such, indeed, is his eagerness in the cause, that he stoops to the most despicable pun, or to the most awkward perversion of language, for the pleasure of turning the scripture into ribaldry, or calling Jesus an impostor.

Yet of the Christian religion has Mr Gibbon himself observed, that it "contains a pure, benevolent, and universal system of ethics, adapted to every duty and every condition of life." Such an acknowledgement, and from such a writer, too, ought to have due weight with a certain class of readers, and of authors likewise, and lead them seriously to consider, how far it is consistent with the character of good citizens to endeavour, by sly insinuations, oblique hints, indecent sneer, and profane ridicule, to weaken the influence of so *pure* and *benevolent* a system as that of Christianity, acknowledged to be admirably calculated for promoting the happiness of individuals, and the welfare of society.

Mr Hayley, in his poetical Essay on History, after a splendid panegyric on the arduous labours of his friend, laments the irreligious spirit by which he was actuated.

Think not my verse means blindly to engage
In rash defence of thy profaner page!
Though keen her spirit, her attachment fond,
Base service cannot suit with Friendship's bond;
Too firm from Duty's sacred path to turn,
She breathes an honest sigh of deep concern,
And pities Genius, when his wild career
Gives Faith a wound, or Innocence a tear.
Humility herself divinely mild,
Sublime religion's meek and modest child,
Like the dumb son of Crœsus, in the strife,
Where force assail'd his father's sacred life,
Breaks silence, and with filial duty warm,
Bids thee revere her parent's hallow'd form (B)!

The part of the history which gave such offence to his own friend, as well as to the friends of the Christian religion in general, was the account which our historian has given of the progress and establishment of Christianity in the two last chapters of his first volume; in which he endeavours to prove, that the wonderful triumph of that religion over all the established religions of the earth, was not owing to any miraculous attestations to its truth, but to five secondary causes which he enumerates: and that Christianity, of course, could not be of divine origin. Several answers appeared on this occasion, written, as we may naturally suppose, with different degrees of temper and ability (C).

One of them only, Mr Davis, who had undertaken to point out various instances of misrepresentation, inaccuracy, and even plagiarism, in his account, did our historian condescend particularly to answer, and that in a tone of proud contempt and confident superiority. To this Mr Davis replied; and it is but justice to observe, that his reply bears evident marks of learning, judgment, and critical acumen; and that he has convicted our author of sometimes quoting inaccurately to serve a purpose. At his other answerers Mr Gibbon merely glanced, treating Dr Watson, however, with particular respect; but his posthumous memoirs shew how much he felt the attacks made on him by Lord Hailes, Dr White, of Oxford, and Mr Taylor. To Dr Priestley, who, in his *History of the Corruptions of Christianity*, threw down his gauntlets at once to Bishop Hurd and the historian of the Roman empire, and who presented the latter with a copy of his book, declaring, at the same time, that he sent it not as a gift but as a *challenge;* he wrote in such terms as produced a correspondence, which certainly added not to the honour of the dissenting divine.

At the beginning of the memorable contest between Great Britain and America, our author was returned, by the interest of Mr Eliot (now Lord Eliot), for the borough of Liskeard, and supported with many a sincere and silent vote, the rights, though not, perhaps, the interest, of the mother country. "After a fleeting illusive hope, prudence condemned me (says he) to acquiesce in the humble station of a mute. I was not armed by Nature and education with the intrepid energy of mind and voice.

Vincentem strepitus, et natum rebus agendis.

Timidity was fortified by pride; and even the success of my pen discouraged the trial of my voice."

That pen, however, was useful to the ministry whom he could not support by his eloquence in the house. At the request of the Lord Chancellor and Viscount Weymouth, then secretary of state, he vindicated, in a very able manner, against the French manifesto, the justice of the British arms, and his *Memoire Justificatif*, was delivered as a state paper to the courts of Europe. He was rewarded for this service with the place of one of the lords commissioners of trade and plantations; and kept it, till the board was abolished by Mr Burke's reform bill. For accepting this place he was severely, but most unjustly, blamed by some of the leaders of the opposition,

(B) Herodotus relates, that a Persian soldier, at the storming of Sardis, was preparing to kill Crœsus, whose person he did not know, and who, giving up all as lost, neglected to defend his own life. A son of the unfortunate monarch, who had been dumb from his infancy, and who never spoke afterward, found utterance in that trying moment, and preserved his father by exclaiming, 'O kill not Crœsus!'

(C) Dr Chelsum, Dr Randolph, Dr Watson (bishop of Llandaff) Lord Hailes, Dr White, Mr Apthorp, Mr Davis, and Mr Taylor, the author of 'The Letters of Ben Mordecai.'

oppoſition, as if he had deſerted a party in which he had never enliſted, and to the principles of which he was rendered inimical both by family prepoſſeſſion and by his own judgment.

On the downfal of Lord North's adminiſtration, Mr Gibbon was of courſe in the oppoſition deprived of an office, without the ſalary of which he could not conveniently ſupport the expence of living in London. The coalition was indeed ſoon formed, and his friends were again in power; but having nothing to give him immediately, they could not detain him in parliament or even in England. He was tired of the buſtle of the metropolis, and ſighed once more for the retirement of Lauſanne, at which he arrived before the overthrow of the coalition miniſtry, and where he lived happily till the laſt years of his life. It was in this retreat that he wrote the fourth, fifth, and ſixth volumes of his hiſtory; and he left it only for a year to ſuperintend the publication of theſe volumes in London. This great work being concluded, he returned to the banks of the Leman lake, but found his enjoyments damped by the diſtreſs and ſoon afterwards by the death of his oldeſt and deareſt Swiſs friend. Lauſanne had now loſt much of its attraction; the French revolution had crowded it with unfortunate emigrants, who could not be cheerful themſelves or excite the cheerfulneſs of others; and the demons of democracy had begun to poiſon the minds of the ſober citizens with principles which Mr Gibbon had always held in abhorrence. Speaking of theſe principles and their effects in Switzerland, he adds, "I beg leave to ſubſcribe my aſſent to Mr Burke's creed on the revolution of France. I admire his eloquence, I approve his politics, I adore his chivalry, and I can almoſt excuſe his reverence for church eſtabliſhments. While the ariſtocracy of Berne protects the *happineſs*, it is ſuperfluous to enquire whether it be founded in the *rights* of men: the economy of the ſtate is liberally ſupplied without the aid of taxes: and the magiſtrates *muſt* reign with prudence and equity, ſince they are unarmed in the midſt of an armed nation."

It was againſt the beneficent and mild government of Berne that the emiſſaries of France contrived to excite the diſcontents of the people, by inſtilling into their ſimple and untutored minds their own wild notions of liberty and equality. From the effects of this Gallic phrenzy, which began to be very viſible ſo early as the beginning of the year 1792, Mr Gibbon reſolved to take ſhelter in England, and to abandon, for ſome time at leaſt, what he called his paradiſe at Lauſanne. Difficulties intervened, and forced him to poſtpone his journey from week to week, and from month to month; but on receiving the accounts of Lady Sheffield's death, he haſtened to adminiſter conſolation to his friend, and arrived ſafe in London in the beginning of June 1793.

He continued in good health and ſpirits through the whole of the ſummer; but his conſtitution had ſuffered much from repeated attacks of the gout, and from an incipient dropſy in his ancles. The ſwelling of his ancles, however, ſubſided; but it was only in conſequence of the water flowing to another place; and being repeatedly tapped for a *hydrocele*, he at laſt ſunk under it, and died at his lodgings in St James's ſtreet, London, on the 16th of January, 1794.

To draw a character at once general and juſt of this extraordinary man, would be difficult perhaps to one who had enjoyed the pleaſure of his acquaintance, and muſt be impoſſible to thoſe to whom his perſon was a ſtranger. Of the extent of his erudition there can be but one opinion; but various opinions may be held reſpecting the accuracy of his knowledge. Lord Sheffield, who knew him well, and loved him much, aſſures us, that his converſation was ſtill more captivating than his writings: but this could not reſult from the brilliancy of his wit; for of wit he declares himſelf that he had none. His memory was capacious and retentive, his penetration uncommon, and his colloquial eloquence ready and elegant; ſo that he could illuſtrate almoſt any topic of converſation from the copious ſtores of his own mind. From his private correſpondence, and a journal not written for the public eye, he appears to have been a dutiful ſon, a loyal ſubject, and an affectionate and ſteady friend; but it is dificult to reconcile with ſo much moral and political worth his unfair and unmanly ſneers at the religion of his country.

GIBRALTAR is a fortreſs of immenſe ſtrength, of which a very full account has been given in the *Encyclopædia*. Nothing, however, is in that article ſaid of the natural hiſtory of the mountain on which the fortreſs is built, though, to men of ſcience, that ſubject muſt be as intereſting as a detail of ſieges. This defect we are enabled to ſupply by means of Major Imrie's mineralogical deſcription of Gibraltar, which is publiſhed in the fourth volume of the Tranſactions of the Royal Society of Edinburgh; and, we are perſuaded, the following abſtract of that elegant memoir will afford rational entertainment to many of our readers.

"The form of this mountain is oblong; its ſummit a ſharp craggy ridge; its direction is nearly from north to ſouth; and its greateſt length, in that direction, falls very little ſhort of three miles. Its breadth varies with the indentations of the ſhore, but it no where exceeds three quarters of a mile. The line of its ridge is undulated, and the two extremes are ſomewhat higher than its centre.

"The ſummit of the Sugar Loaf, which is the point of its greateſt elevation towards the ſouth, is 1439 feet; the Rock Mortar, which is the higheſt point to the north, is 1350; and the Signal Houſe, which is nearly the central point between theſe two, is 1276 feet above the level of the ſea. The weſtern ſide of the mountain is a ſeries of rugged ſlopes, interſperſed with abrupt precipices. Its northern extremity is perfectly perpendicular, except towards the north-weſt, where what are called the Lines intervene, and a narrow paſſage of flat ground that leads to the iſthmus, and is entirely covered with fortification. The eaſtern ſide of the mountain moſtly conſiſts of a range of precipices; but a bank of ſand riſing from the Mediterranean in a rapid acclivity, covers a third of its perpendicular height. Its ſouthern extremity falls, in a rapid ſlope from the ſummit of the Sugar Loaf, into a rocky flat of conſiderable extent, called Windmill Hill.

"The principal maſs of the mountain rock conſiſts of a grey, denſe (what is generally called primary) marble; the different beds of which are to be examined in a face of 1350 feet of perpendicular height, which it preſents to Spain in a conical form. Theſe beds, or ſtrata, are of various thickneſs, from 20 to upwards of 40 feet, dipping in a direction from eaſt to weſt, nearly at an angle of 35 degrees. In ſome parts of the ſaid mass of this rock are found testaceous bodies entirely transmuted into the constituent matter of the rock, and their interior hollows filled up with calcareous spar; but these do not occur often in its composition, and its beds are not separated by any intermediate strata.

"The caves of Gibraltar are many, and some of them of great extent. That which most deserves attention and examination is called St Michael's Cave, which is situated upon the southern part of the mountain, almost equally distant from the Signal Tower and the Sugar Loaf. Its entrance is 1000 feet above the level of the sea: This entrance is formed by a rapid slope of earth, which has fallen into it at various periods, and which leads to a spacious hall, incrusted with spar, and apparently supported in the centre by a large massy stalactitical pillar. To this succeeds a long series of caves of difficult access. In these cavernous recesses, the formation and process of stalactites is to be traced, from the flimsy quilt-like cone, suspended from the roof, to the robust trunk of a pillar, three feet in diameter, which rises from the floor, and seems intended by Nature to support the roof from which it originated.

"The only inhabitants of these caves are bats, some of which are of a large size. The soil, in general, upon the mountain of Gibraltar is but thinly sown; and in many parts that thin covering has been washed off by the heavy autumnal rains, which have left the superfices of the rock, for a considerable extent, bare and open to inspection. In those situations, an observing eye may trace the effects of the slow, but constant, decomposition of the rock, caused by its exposure to the air, and the corrosion of sea salts, which, in the heavy gales of easterly winds, are deposited with the spray on every part of the mountain. Those uncovered parts of the mountain rock also expose to the eye a phenomenon worthy of some attention, as it tends clearly to demonstrate, that, however high the surface of this rock may now be elevated above the level of the sea, it has once been the bed of agitated waters. This phenomenon is to be observed in many parts of the rock, and is constantly found in the beds of torrents. It consists of pot-like holes, of various sizes, hollowed out of the solid rock, and formed apparently by the attrition of gravel or pebbles, set in motion by the rapidity of rivers or currents in the sea.

"Upon the west side of the mountain, towards its base, some strata occur, which are heterogenial to the mountain rock: the first, or highest, forms the segment of a circle; its convex side is towards the mountain, and it slopes also in that direction. This stratum consists of a number of thin beds; the outward one, being the thinnest, is in a state of decomposition, and is mouldering down into a blackish brown or ferruginous coloured earth. The beds, inferior to this, progressively increase in breadth to 17 inches, where the stratification rests upon a rock of an argillaceous nature.

"This last bed, which is 17 inches thick, consists of quartz of a blackish blue colour, in the septa or cracks of which are found fine quartz crystals, colourless, and perfectly transparent. These crystals are composed of 18 planes, disposed in hexangular columns, terminated at both extremities by hexangular pyramids. The largest of these that Major Imrie saw did not exceed one-fourth of an inch in length: They, in general, adhere to the rock by the sides of the column, but are detached without difficulty. Their great degree of transparency has obtained them the name of *Gibraltar diamonds*."

Much has been said of the fossil bones found in the rock of Gibraltar; and the general idea which exists concerning them is, that they are found in a petrified state, and inclosed in the solid calcareous rock; but this, says Major Imrie, is a mistake, which could arise only from inaccurate observation and false description.

"In the perpendicular fissures of the rock, and in some of the caverns of the mountain (all of which afford evident proofs of their former communication with the surface), a calcareous concretion is found, of a reddish brown ferruginous colour, with an earthy fracture, and considerable induration, inclosing the bones of various animals, some of which have the appearance of being human. These bones are of various sizes, and lie in all directions, intermixed with shells of snails, fragments of the calcareous rock, and particles of spar; all of which materials are still to be seen in their natural uncombined states, partially scattered over the surface of the mountain. These having been swept, by heavy rains at different periods, from the surface into the situations above described, and having remained for a long series of years in those places of rest, exposed to the permeating action of water, have become inveloped in, and cemented by, the calcareous matter which it deposits.

"The bones, in this composition, have not the smallest appearance of being petrified: and if they have undergone any change, it is more like that of calcination than that of petrifaction, as the most solid parts of them generally admit of being cut and scraped down with the same ease as chalk.

"Bones combined in such concretions are not peculiar to Gibraltar: they are found in such large quantities in the country of Dalmatia, and upon its coasts in the islands of Cherso and Osero, that some naturalists have been induced to go so far as to assert, that there has been a regular stratum of such matter in that country, and that its present broken and interrupted appearance has been caused by earthquakes, or other convulsions, experienced in that part of the globe. But, of late years, a traveller (Abbé Alberto Fortis) has given a minute description of the concretion in which the bones are found in that country: And by his account it appears, that with regard to situation, composition, and colour, it is perfectly similar to that found at Gibraltar. By his description, it also appears that the two mountain rocks of Gibraltar and Dalmatia consist of the same species of calcareous stone; from which it is to be presumed, that the concretions in both have been formed in the same manner and about the same periods.

"Perhaps if the fissures and caves of the rock of Dalmatia were still more minutely examined, their former communications with the surface might yet be traced, as in those described above; and, in that case, there would be at least a strong probability, that the materials of the concretions of that country have been brought together by the same accidental cause which has probably collected those found in the caverns of Gibraltar. Major Imrie traced, in Gibraltar, this concretion, from the lowest part of a deep perpendicular fissure, up to the surface of the mountain. As it approached to the surface, the concretion became less firmly combined, and, when it had no covering of the calcareous rock, a small degree of adhesion only remained, which was evidently

Gibraltar. dently produced by the argillaceous earth, in its composition, having been moistened by rain and baked by the sun.

"The depth at which these materials had been penetrated by that proportion of stalactitical matter, capable of giving to the concretion its greatest adhesion and solidity, he found to vary according to its situation, and to the quantity of matter to be combined. In fissures, narrow and contracted, he found the concretion possessing a great degree of hardness at six feet from the surface; but in other situations more extended, and where a larger quantity of the materials had been accumulated, he found it had not gained its greatest degree of adhesion at double that depth. In one of the caves, where the mass of concretion is of considerable size, he perceived it to be divided into different beds, each bed being covered with a crust of the stalactitical spar, from one inch to an inch and a half in thickness, which seems to indicate, that the materials have been carried in at various periods, and that those periods have been very remote from each other.

"At Rosia Bay, upon the west side of Gibraltar, this concretion is found in what has evidently been a cavern, originally formed by huge unshapely masses of the rock which have tumbled in together. The fissure, or cavern, formed by the disruption and subsidence of those masses, has been entirely filled up with the concretion, and is now exposed to full view by the outward mass having dropped down in consequence of the encroachments of the sea. It is to this spot that strangers are generally led to examine the phenomenon; and the composition, having here attained to its greatest degree of hardness and solidity, the hasty observer seeing the bones inclosed in what has so little the appearance of having been a vacuity, examines no further, but immediately adopts the idea of their being incased in the solid rock. The communication from this former chasm, to the surface from which it has received the materials of the concretion is still to be traced in the face of the rock, but its opening is at present covered by the base of the line wall of the garrison. Here bones are found that are apparently human; and those of them that appear to be of the legs, arms, and vertebræ of the back, are scattered among others of various kinds and sizes, even down to the smallest bones of small birds. Major Imrie found here the complete jaw-bone of a sheep; it contained its full complement of teeth, the enamel of which was perfect, and its whiteness and lustre in no degree impaired. In the hollow parts of some of the large bones was contained a minute crystallization of pure and colourless calcareous spar; but, in most, the interior part consisted of a spary crust of a reddish colour, scarcely in any degree transparent.

"At the northern extremity of the mountain, the concretion is generally found in perpendicular fissures. The miners there, employed upon the fortifications in excavating one of those fissures, found, at a great depth from the surface, two skulls, which were supposed to be human; but, to the Major, one of them, if not both, appeared to be too small for the human species. The bone of each was perfectly firm and solid; from which it is to be presumed, that they were in a state of maturity before they were inclosed in the concretion. Had they appertained to very young children, perhaps the bone would have been more porous and of a less firm texture. The probability is, that they belonged to a species of monkey, which still continues to inhabit, in considerable numbers, those parts of the rock which are to us inaccessible.

"This concretion varies, in its composition, according to the situation in which it is found. At the extremity of Princes Lines, high in the rock which looks towards Spain, it is found to consist only of a reddish calcareous earth, and the bones of small birds cemented thereby. The rock around this spot is inhabited by a number of hawks, that, in the breeding season nestle here and rear their young; the bones in this concretion are probably the remains of the food of those birds. At the base of the rock below King's Lines, the concretion consists of pebbles of the prevailing calcareous rock. In this concretion, at a very considerable depth under the surface, was found the under parts of a glass bottle, uncommonly shaped, and of great thickness; the colour of the glass was of a dark green."

Major Imrie makes an apology for giving so minute a description of these fossil bones; but, in our opinion, the public is indebted to him for bestowing so much attention on a subject which all must admit to be curious, and which, from the strange inferences drawn from similar phenomena by modern philosophers, has become important as well as curious.

We cannot dismiss this article without noticing the subterraneous galleries constructed in the rock not only for the protection of the men during a siege, but also for placing cannon, to annoy the enemy, in situations inaccessible but by such means. The idea of forming these galleries was conceived by the late Lord Heathfield when governor, and by him in some measure, carried into execution; though the plan was not completed till lately by General O'Hara. Of these galleries we have in the *Monthly Magazine* for April 1798 an animated account, which we shall insert in the writer's own words.

"The subterraneous galleries are very extensive, pierce the rock in several places and in various directions, and at various degrees of elevation; all of them have a communication with each other, either by flights of steps cut in the rock, or by wooden stairs where the passages are required to be very perpendicular.

"The centinels may now be relieved during a siege from one post to another in perfect safety; whereas, previously to the constructing of these galleries, a vast number of men were killed by the Spaniards while marching to their several stations. The width of these galleries is about twelve feet, their height about fourteen. The rock is broken through in various places, both for the purpose of giving light and for placing the guns to bear on the enemy. In different parts there are spacious recesses, capable of accommodating a considerable number of men. To these recesses they give names, such as St Patrick's Chamber, St George's Hall, &c. The whole of these singular structures have been formed out of the solid rock by blasting with gunpowder. Through the politeness of an officer on duty, a place called Smart's Reservoir was opened for our inspection, which is a great curiosity, and not generally permitted to be shewn. It is a spring at a considerable depth in the body of the rock, and is above 700 feet above the level of the sea; we descended into the cavern that contains it by a rope ladder, and with the aid of lighted candles

candles proceeded through a narrow paſſage over cryſtallized protuberances of the rock till we came to a hollow, which appears to have been opened by ſome convulſion of Nature. Here, from a bed of gems, ariſes the ſalutary fount, clear as the brilliant of the eaſt, and cold as the iſicle. We hailed the nymph of the grot, and, proſtrating ourſelves, quaffed hygean nectar from her ſparry urn. When reſtored to the light of day, we obtained, through the medium of the ſame gentleman, the key of St George's Hall, at which we arrived by a very intricate and gloomy path to the ſpacious excavation, which is upwards of an hundred feet in length, its height nearly the ſame. It is formed in a ſemicircular part of the rock; ſpacious apertures are broken through, where cannons of a very large calibre command the iſthmus, the Spaniſh lines, and a great part of the bay. The top of the rock is pierced through, ſo as to introduce ſufficient light to enable you to view every part of it. It appears almoſt incredible that ſo large an excavation could be formed by gunpowder, without blowing up the whole of that part of the rock, and ſtill more ſo, that they ſhould be able to direct the operations of ſuch an inſtrument, ſo as to render it ſubſervient to the purpoſe of elegance. We found in the hall a table, placed, I ſuppoſe, for the conveniency of thoſe who are traverſing the rock. The cloth was ſpread, the wine went round, and we made the vaulted roof reſound with the accents of mirth and the ſongs of conviviality."

Theſe excavations are indeed very extraordinary works; but as the whole rock abounds with caverns, we wiſh that our author had inquired more particularly than he ſeems to have done, whether St George's Hall be wholly the work of art. From one of the paſſages which we have extracted from Major Imrie's memoir, we are led to think that it is not, or, at leaſt, that the concretion removed had not acquired the conſiſtence of the more ſolid parts of the rock. If this was the caſe, much of the wonder will vaniſh ſince the pick-axe and chiſel were probably employed to give elegance to the vault, and even, in ſome degree, to direct the operation of the gunpowder.

GIBRALTER, an ancient town in the province of Venezuela, in Terra Firma. It is ſituated on the ſouth-eaſtern ſide of Maracaibo Lake. The country in its vicinity is well watered with rivers, and bears the beſt quality of cacao, and very large cedars. The beſt Spaniſh tobacco is made here, called Tabago de Maracaibo, from which the valuable ſnuff is made, vulgarly called *Mackaba* ſnuff. The air, however, is ſo unhealthy, that very few but labourers live in the town; the wealthier ſort reſorting to Merida or Maracaibo. —*Morſe.*

GILL, a new townſhip in Hampſhire co. Maſſachuſetts, on the weſt bank of Connecticut river, a little below the mouth of Miller's river, on the oppoſite ſide, and named after his Honor, Moſes Gill, Lieutenant-Governor of Maſſachuſetts.—*ib.*

GILLORI, an iſland on the coaſt of Weſt-Florida, is divided from Dauphin Iſland by a narrow channel, through which a boat may paſs with ſome difficulty; and between Gillori and the main land, on the weſt ſide of Mobile Bay, there is a chain of ſmall iſlands, and oyſter ſhells, through which is a paſſage of 4 feet called Paſſe au Heron.—*ib.*

GILMANTOWN, a townſhip in Strafford co. New-Hampſhire, ſouth-weſterly of Lake Winnipiſeogee, and 52 miles N. W. of Portſmouth. It was incorporated in 1727, and contained 775 inhabitants in 1775; and in 1790, 2613.—*ib.*

GIMBOLS, are the braſs rings by which a ſea compaſs is ſuſpended in its box that uſually ſtands in the binacle.

GIRT, in timber-meaſuring, is the circumference of a tree, though ſome uſe this word for the quarter or 4th part of the circumference only, on account of the great uſe that is made of it; for the ſquare of this 4th part is eſteemed and uſed as equal to the area of the ſection of the tree; which ſquare therefore multiplied by the length of the tree, is accounted the ſolid content. This content, however, is always about one-fourth part leſs than the true quantity; being nearly equal to what this will be after the tree is hewed ſquare in the uſual way: ſo that it ſeems intended to make an allowance for the ſquaring of the tree.

Girt-*Line*, is a line on the common or carpenter's ſliding rule, employed in caſting up the contents of trees by means of their girt.

GIRTY'*s Town*, an Indian village in the N. W. Territory, near the head of the navigable water or landing on St Mary's river, where the Indians ceded at the treaty of Greenville, a tract of 2 miles ſquare to the United States.—*Morſe.*

GLADE *Road*, at Bonnets' tavern, 4 miles from Bedford, on the road from Philadelphia to Pittſburg Forks; the ſouthernmoſt is called the Glade Road; the northernmoſt the *Old*, or *Forbes's Road*, and goes by Ligonier. Theſe roads unite 28 miles from Pittſburg. In the *Glades*, a tract of country at the entrance of the Alleghany Mountains, they cannot raiſe corn, as the earth is ſubjected to froſt from Sept. to June. —*ib.*

GLADY *Creek*, a ſmall ſtream which flows through the eaſt bank of Little Miami river in the N. W. Territory.—*ib.*

GLAIZE, *Au*, a S. S. W. branch of the Miami of the Lake, which interlocks with St Mary's river. By the treaty at Greenville, the Indians have ceded to the United States a tract of land 6 miles ſquare, at the head of its navigable waters, and 6 miles ſquare at its confluence with the Miami, where Fort Defiance now ſtands.—*ib.*

GLASGOW, a new county in Newbern diſtrict, N. Carolina, taken from Dobbs' co. It is bounded N. by Edgcomb, S. by Lenoir, E. by Pitt, and W. by Wayne.—*ib.*

GLASS Etching, or *Engraving upon*, is in the article Chemistry *(Encycl.)* ſaid to be a new art; and as that acid which diſſolves ſiliceous earth, and alſo glaſs, was firſt diſcovered in the year 1771 by Scheele, one might naturally imagine that the art of etching with it upon glaſs could not be older. By many others, as well as by us, it has indeed been noticed as a new invention; yet Profeſſor Beckmann, whoſe laborious reſearches have brought many things to light, has proved, that ſo early as the year 1670 the art of etching upon glaſs was diſcovered by Henry Schwanhard, ſon of George Schwanhard, who was a celebrated glaſs-cutter, patronized by the Emperor Ferdinand

Glafs Etching.

nand III. about the middle of the laft century. At the time of his death, 1667, the father practifed his art at Prague and Ratifbon. Whether the fon followed the fame bufinefs at the fame towns, or removed to Nuremberg, is not very evident from the profeffor's hiftory; but in the year above-mentioned, fome *aqua regia* (*nitro-muriatic acid*) having accidentally fallen on his fpectacles, he was furprifed to find the glafs corroded by it, and become quite foft. He thus found himfelf in poffeffion of a liquid by which he could etch writing and figures upon plates of glafs.

Such is our information; but if it be admitted (and it would difplay unreafonable fcepticifm to queftion it), Schwanhard muft either have improved the nitro-muriatic acid by fome means or other unknown to us, or have confined his etchings to fome particular kinds of glafs; for the *fluoric* is the only acid, with which we are acquainted, that corrodes all glafs. (See CHEMISTRY-*Index* in this *Supplement*). M. Beckmann indeed feems to think that he had difcovered the fluoric acid itfelf; for in the year 1725 there appeared in a periodical work the following receipt for making a powerful acid, by which figures of every kind can be etched upon glafs.

"When the *fpiritus nitri per diftillationem* has paffed into the recipient, ply it with a ftrong fire, and when well dephlegmated, pour it, as it corrodes ordinary glafs, into a Weldenburg flafk. Then throw into it a pulverifed green Bohemian emerald, otherwife called *hefphorus* (which, when reduced to powder, and heated, emits in the dark a green light), and place it in warm fand for 24 hours. Take a piece of glafs well cleaned, and freed from all greafe by means of a ley; put a border of wax round it, about an inch in height, and cover it all over with the above acid. The longer you let it ftand fo much the better; and at the end of fome time the glafs will be corroded, and the figures which have been traced out with fulphur and varnifh will appear as if raifed above the pane of glafs."

That the Bohemian emerald or *hefphorus* mentioned in this receipt is green fparry fluor, cannot, fays the profeffor, be doubted; and he feems to have as little doubt of the receipt itfelf having paffed from Schwanhard and his fcholars to the periodical work of 1725, from which it has been lately inferted in the Œkonomifche Encyclopedie of Krunitz. This fuppofition certainly acquires a confiderable degree of probability from the fimilarity of Schwanhard's method of etching to that which is here recommended, and which is fo different from what is now followed. At prefent, the glafs is covered with a varnifh either of ifinglafs diffolved in water, or of turpentine oil mixed with a little white lead, through which the figures to be etched are traced as on copper; but Schwanhard, when he had drawn his figures, covered them with varnifh, and then by his liquid corroded the glafs around them. His figures, therefore, when the varnifh was removed, remained fmooth and clear, appearing raifed from a dim or dark ground; and M. Beckmann, who perfuaded fome ingenious artifts to make trial of this antient method of etching, declares, that fuch figures have a much better effect than thofe which are cut into the glafs.

Before concluding this article, it may be worth while juft to mention a propofal which has been lately made to employ glafs inftead of copper for throwing off prints in the rolling prefs. That it is poffible to ufe glafs plates of great thicknefs for this purpofe, it would be rafh to deny; but the fuperiority of fuch plates to thofe of copper we cannot conceive. If not broken in pieces in the rolling prefs, they would doubtlefs laft longer; but the expence of them at firft would probably be greater, and the engraving on them could not be fo fine.

Glaftonbury || Gloucefter.

GLASTONBURY, a townfhip in Bennington co. Vermont, having only 34 inhabitants. It has good intervale lands, and lies N. E. of Bennington, adjoining.—*Morse.*

GLASTONBURY, a handfome little town in Hartford co. Connecticut, fituated on the eaft fide of Connecticut river, oppofite to Weathersfield, and of which it formed a part until 1690. In the townfhip are 2 meeting houfes; and on Roaring Brook and other fmall ftreams are 17 mills of different kinds and 1 forge.—*ib.*

GLOSSOCOMMON, in mechanics, is a name given by Heron to a machine compofed of divers dented wheels with pinions, ferving to raife huge weights.

GLOUCESTER *Houfe*, belonging to the Hudfon's Bay Company, is fituated in New South Wales, on the N. fide of the waters which form a communication through a chain of fmall lakes, between Winnepeg Lake and Albany river. Henley Houfe lies N. E. of this, nearer the mouth of Albany river, in James' Bay. N. lat. 54. W. long. 87. 30.—*Morse.*

GLOUCESTER, or *Cape-Ann*, a townfhip in Effex co. Maffachufetts, whofe eaft point forms the north fide of the bay of Maffachufetts. It contains 5317 inhabitants, and is divided into 5 parifhes, and has befides a fociety of Univerfalifts. This is a poft-town and port of entry. The harbour is very open and acceffible to large fhips; and is one of the moft confiderable fifhing towns in the Commonwealth. At the harbour, properly fo called, are fitted out annually from 60 to 70 bankers; and from Squam and Sandy Bay, two fmall out ports, the bay fifhery is carried on with great fpirit, and to a large amount. The exports for one year, ending Sept. 30, 1794, amounted in value to 229,613 dollars. Thatcher's Ifland, on which are two lights of equal height, lies clofe to the S. E. fide of the townfhip, which is itfelf joined to the continent by a beach of fand which is very rarely overflowed by the water. There is a very fine white fand here fit for making glafs. The harbour is defended by a battery and citadel erected in 1795. It is 16 miles N. E. by E. of Salem, and 34 N. E. of Bofton.—*ib.*

GLOUCESTER, the north-wefternmoft townfhip, and the largeft, in Providence co. Rhode-Ifland, having Connecticut on the weft, and Maffachufetts on the north; and contains 4025 inhabitants.—*ib.*

GLOUCESTER *County*, in New-Jerfey, is bounded north by Burlington co. fouth by Salem, Cumberland, and Cape May counties, eaft by the Atlantic Ocean, and weft by Delaware river. Its length on the Delaware is about 30 miles, and on the fea the line is about 22 miles. Great and Little Egg Harbour rivers are both navigable for veffels of 200 tons about 20 miles from their mouths. The ftreams which fall into Delaware river are navigable for fmall veffels, a few miles up from their mouths, and afford fome fhad, rock, herrings, and perch. The adjacent iflands are Red Bank, Pett, and Old Man's Creek Iflands. The firft of of which is famous in the history of the American war, for the desperate defence the garrison upon it made, to prevent the British fleet from passing up to Philadelphia. The soil of this county is a mixture of sand and loam, and the tract bordering on the Delaware is in a high state of cultivation. The chief productions are beef, pork, fish, hay, corn, lumber, butter, cheese, &c. It is divided into 10 townships, viz. Woodbury, Waterford, Newtown, Gloucester Township, Gloucester Town, Deptford, Greenwich, Woolwich, Egg Harbour, and Galloway. The first 8 lie along the Delaware, and the other two on the ocean. Mulicus river divides this county from Burlington, and is navigable 20 miles for vessels of 60 tons. Maurice river rises here, runs southerly about 40 miles through Cumberland co. into Delaware Bay, is navigable for vessels of 100 tons 15 miles, and for shallops 10 miles farther. It contains 13,172 free inhabitants, and 191 slaves. There are found in this county quantities of bog iron ore, which is manufactured into pig and bar iron, and hollow ware. Here is also a glass-house. Chief town, Woodbury, 9 miles S. of Philadelphia.—*ib.*

GLOUCESTER, a small town in the above county, on the east side of Delaware river, 3 miles below Philadelphia. It was formerly the county town, but has now scarcely the appearance of a village.—*ib.*

GLOUCESTER, a post-town in Virginia, situated in the county of its own name, on a point of land on the N. side of York river, partly opposite York-Town, 17 miles distant.—*ib.*

GLOUCESTER *County*, in Virginia, is fertile and well cultivated, bounded N. by Piankitank river, which separates it from Middlesex, east by Mathews co. and Chesapeak Bay, N. W. by King and Queen, S. and S. W. by York river, which divides it from York co. It is about 55 miles in length, and 30 in breadth, and contains 13,498 inhabitants, including 7063 slaves. The low lands here produce excellent barley, and Indian corn, the staple produce of the county. Tobacco is little attended to.—*ib.*

GLOUCESTER *House*, in the territory of the Hudson's Bay Company, is on the N. side of Musquacobaston Lake, 120 miles west of Osnaburgh house. N. lat. 51. 24. W. long. 86. 59.—*ib.*

GLUCINA (A), a peculiar earth discovered by Vauquelin in the beryl and the emerald. Its general properties are as follows: 1. It is white: 2. Insipid; 3. Insoluble in water; 4. Adhesive to the tongue; 5. Infusible; 6 Soluble in the fixed alkalis; 7. Insoluble in ammoniac; 8. Soluble in the carbonate of ammoniac; 9. Soluble in almost every one of the acids (except the carbonic and phosphoric acids), and forming salts of a saccharine taste; 10. Fusible with borax into a transparent glass; 11. Absorbs one fourth of its weight of carbonic acid; 12. Decomposes the aluminous salts; 13. Is not precipitable by well saturated hydro sulphurets.

The specific characters of glucina, which are united in none of the other known earths, are; 1. Its salts are saccharine, and slightly astringent; 2. It is very soluble in the sulphuric acid by excess; 3. It decomposes the aluminous salts; 4. It is soluble in the carbonate of ammoniac; 5. Is completely precipitated from its solutions by ammoniac; 6. Its affinity for the acids is intermediate between magnesia and alumine.

One hundred parts of beryl contain 16 of glucina; but for the best method of analyzing the beryl, and of course obtaining the earth, we must refer our readers to the article MINERALOGY in this *Supplement;* and shall conclude this short article with a valuable and judicious remark of Vauquelin's.

"It almost always happens (says this able chemist), in the sciences of observation, and even in the speculative sciences, that a body, a principle, or a property, formerly unknown, though it may often have been used, or even held in the hands, and referred to other simple species, may, when once discovered, be afterwards found in a great variety of situations, and be applied to many useful purposes. Chemistry affords many recent examples of this truth. Klaproth had no sooner discovered the different substances with which he has enriched the science, but they were found in various other bodies; and if I may refer to my own processes, it will be seen, that after I had determined the characters of chrome, first found in the native red lead, I easily recognized it in the emerald and the ruby. The same has happened with regard to the earth of the beryl. I have likewise detected it in the emerald; in which, nevertheless, it was overlooked both by Klaproth and myself in our first analysis: so difficult it is to be aware of the presence of a new substance, particularly when it possesses some properties resembling those already known!"

GLYNN *County*, in the Lower district of Georgia, bounded east by the ocean, north by Alatamaha river, which separates it from Liberty co. and south by Camden co. It contains 413 inhabitants, including 215 slaves. Chief town, Brunswick.—*Morse.*

GNADENHUETTEN, or *Gnadenhutten*, a settlement of the Moravians, or United Brethren, on Muskingum river, opposite to Salem, in the lands which belonged to the Mahikan Indians. In 1746 it was a pleasant town, inhabited by Christian Indians, where were a chapel, missionary's house, and many Indian houses. This together with Schoenbrun and Salem were reserved by Congress, by an ordinance, May 20, 1785, for the Christian Indians formerly settled there; Sept. 3, 1788, it was resolved that the plat of each town should make up 4,000 acres, and the grant was made to the United Brethren for propagating the gospel among the heathen.—Also the name of a Moravian settlement on the south-west bank of Lehigh river, in Pennsylvania, about 29 miles north-west of Bethlehem.—*ib.*

GOAT *Island*, in the State of Rhode-Island, a small islot, opposite to the town of Newport, and on which is Fort Washington. The fort has been lately repaired, and a citadel erected in it. The fort has been ceded to the United States.—*ib.*

GOAVE

(A) This name was given to the earth of beryl by the editors of the *Annales de Chemie*. Its most characteristic property being that it forms salts of a saccharine taste, they gave it a name derived from γλυκαινω, *to render sweet*. According to this etymology, should not the name be *Glycina?*

GOAVE LE PETIT, one of the weſt juriſdictions of the French part of St Domingo. It contains 5 pariſhes, is the unhealthieſt part of the colony, the inhabitants being ſubject to conſtant fevers, occaſioned by the badneſs of the waters. Its dependencies, however, are healthy, and remarkable for the culture of coffee. Exports from Jan. 1, 1789, to Dec. 31, of the ſame year; 27,090 lbs white ſugar—655,187 lbs brown—807,865 lbs coffee—50,053 lbs cotton—and 210 lbs indigo. The town of the ſame name is ſituated on the narroweſt part of the ſouth-weſtern peninſula, on the north ſide of the neck.—*Morse.*

GOELANS, Point Au, a promontory on the north ſide of Lake Ontario, about 33 miles ſouth-weſterly of Fort Frontinac.—*ib.*

GOFFSTOWN, in Hillſborough county, New-Hampſhire, on the weſtern bank of Merrimack river, 3 miles from Amuſkeag Falls, and 60 miles weſt of Portſmouth. It was incorporated in 1761, and contains 1,275 inhabitants. Some pieces of baked earthen ware have been found in this townſhip, from which it is ſuppoſed that the Indians had learned the potters art; but of what antiquity theſe remnants are, is uncertain.—*ib.*

GOLD, the moſt perfect of all the metals. See Chemistry-*Index* in this *Supplement*.

It has been a very common opinion among metallurgiſts, that tin has the property of deſtroying the ductility of gold, on being melted with it even in very ſmall quantities; and Dr Lewis adds, that even the vapours which ariſe from tin in the fire, make gold ſo brittle, that it flies in pieces under the hammer. This opinion was controverted by Staneſby Alchorne, Eſq; of his Majeſty's mint, who made a ſet of experiments, which, in his opinion, authoriſe a very different concluſion, viz. that though tin, like other inferior metals, will contaminate gold in proportion to the quantity mixed with it, yet there does not appear in tin any thing ſpecifically inimical to that precious metal.

As we have elſewhere (See Chemistry, n° 1091, &c. *Encycl.*) enumerated theſe experiments, and admitted the concluſion drawn from them, it becomes our duty, in this place, to ſtate what has been urged againſt that concluſion.

M. Tillet, being in his own mind perſuaded that tin renders gold ſo brittle that it cannot be reduced to thin leaves, and far leſs be made to paſs through the wire plate but by virtue of repeated annealing, and peculiar treatment, which gold of the uſual ductility does not require, determined, from reſpect to M. Alchorne, to repeat his experiments.

His firſt experiment * conſiſted in mixing 24 grains of fine gold with one of tin which contained no arſenic. He wrapped the grain of tin in the 24 grains of gold reduced to a very thin leaf, and placed the whole upon a piece of charcoal, ſo hollowed out as to ſupport the mixed metal during fuſion. He even ſprinkled a ſmall quantity of calcined borax upon the metal, in order that the fuſion might be more ſudden, that the metal might flow together, and the tin unite with the gold, without allowing time for it to become calcined. This alloy was ſpeedily fuſed by the enameller's lamp, and reduced into a ſmall button without any loſs of weight. It was then flattened carefully beneath the hammer; but, notwithſtanding his utmoſt precaution in this reſpect, it cracked, and at laſt broke into three pieces, its thickneſs then being a quarter of a line or thereabouts. He repeated this experiment with a double quantity as well of pure gold as of tin, and the reſult was the ſame.

* Memoirs of the Academy of Sciences at Paris for the year 1790.

He next alloyed 4 ounces of gold, of the fineneſs of 22 carats, with 1 gros 24 grains of tin deprived of arſenic, or, in other words, with 4 pennyweights of tin; and theſe two metals being reduced into ſmall pieces, were mixed together, put into a crucible, and urged by the ſtrong heat of a forge with two pair of bellows. When their fuſion appeared to be complete, he poured the metal into a ſmall ingot mould proportioned to the quantity.

The ingot thus obtained had loſt ſcarcely any thing of the weight of the two metals that compoſed it; which was a proof that the tin had united and incorporated with the four ounces of gold. But on attempting to bend the ingot, which was about ſix inches long, and not more than two or three lines thick, he remarked, contrary to the nature of gold of 22 carats, that it was rigid, and would have required a conſiderable effort to give it any degree of curvature, or bring it to the flexibility it would have poſſeſſed if no tin had entered into its compoſition. Not ſatisfied, however, with the inference naturally flowing from this circumſtance, he proceeded to the proper teſt by hammering, particularly with the edge of the hammer, in order that the bar might be lengthened, and by that means ſubmitted to the moſt deciſive proof. He did not obſerve, during the continuation of this proceſs, till the bar was reduced to about two-thirds of its firſt thickneſs, that its edges were cracked, or exhibited much of the appearance of brittleneſs; but as he was apprehenſive that this accident might happen by too long hammering, he divided the bar by cutting off the part which had been hammered out. This part was placed in the midſt of lighted charcoal, in order that, by a moderate annealing, it might recover the ſtate of malleability it poſſeſſed before it was hammered. But when he went to take it out of the fire, where it had undergone no greater heat than a cherry red, he found it divided into two parts. After having ſuffered theſe to cool, he forged them again. They were extended with conſiderable eaſe, though with ſome cracks at the edges; but they did not yet ſatisfy the whole of his enquiries. He therefore annealed one of the two laſt mentioned pieces a ſecond time, and reſerved the other in its hard-hammered ſtate to be paſſed between the laminating rollers. The annealed part, which might have the thickneſs of about a ſhilling, broke in the fire, though the heat was very gentle, into four or five portions. The longeſt of theſe portions, which beſt reſiſted the action of the fire, bent and twiſted itſelf, and ſhewed, by this ſtate of ſtrong contraction in different directions, that it had tended to break and become divided into ſmall portions, ſimilar to thoſe which had already ſeparated from it.

Satisfied by this experiment that the piece of the mixed ingot which he had kept in its hammer-hardened ſtate would not bear annealing, he determined to extend it ſtill more between the rollers, ſetting them up very gradually, in order that the fracture, if it ſhould take place, might be principally owing to the brittleneſs of the material, and not to the force of compreſfion to which it was fubjected. By this management he fucceeded in extending the metal to double its length notwithftanding its hardnefs, and rendering it as thin as ftrong paper; though the edges were cracked through their whole length like the teeth of a faw. But this accident is not at all furprifing, when it is confidered that gold, though alloyed fimply with copper, whatever may be the caufe, does not poffefs its ufual ductility, particularly when it is laminated very thin, without repeated annealing as the metal becomes hard.

Aware that the fracture of the pieces of gold might be attributed to an incomplete fufion, or unequal mixture of the two metals, he melted the whole ingot over again with the utmoft precaution; but in vain. The metal was as brittle as formerly, and would not bear annealing.

He next fufed 6 ounces of pure gold of 24 carats with 2 gros, or 6 penny-weights of tin, taking every poffible precaution to have the metals completely mixed. When the whole was in perfect fufion, he poured the mixture into an ingot mould, and obtained an ingot rather longer and cleaner than the two former. As foon as it was cold he forged one of its extremities with the edge of the hammer. It was lengthened without any perceptible crack; and when it was reduced to the thicknefs of one line, or thereabouts, he cut it off for feparate treatment. By moderate annealing it maintained its integrity; and, with the exception of a few cracks, it paffed the laminating rollers without breaking. As he was fearful, neverthelefs, that it might break in fome part if he continued to laminate it, he gave it a flight annealing. It had fcarcely acquired a cherry-rednefs between the charcoal, before it broke into five or fix parts, fome of which were fimply bended or twifted, and others flat as they quitted the rollers. Among the annealed pieces of this extremity of the ingot, there was one fufficiently long, though a little curled, which he laminated a fecond time, with the determination of rendering it very thin without the leaft annealing. It acquired at leaft double the length it had at firft without breaking; and, if we except the two fides of this plate which were cracked, the body, or main piece, was entire. It was fpongy, and might be confidered as if formed out of an ingot of common gold containing no tin, but not poffeffing the whole of its natural ductility.

"It follows, fays M. Tillet, from thefe experiments, that gold, whether fine or alloyed, when perfectly fufed with a fmall portion of the fineft tin, acquires rigidity and hardnefs by the mixture; that it lofes fomewhat of its diftinguifhing colour; and that it may, indeed, by careful management, be extended to a certain degree by the hammer, or ftill better by the rollers; but that, as it cannot be annealed without danger of breaking, it is by this defect deprived of the effential advantage of recovering its original foftnefs after it has been ftrongly hammer-hardened. It is not but by careful management in the ufe of the hammer, and by frequent annealing, that artifts employed on works of gold and filver fucceed in obtaining them without cracks, and bringing them to a ftate of perfection, without being obliged to have recourfe to folder to repair the defects which exceffive hardnefs under the hammer would occafion. How much, therefore, ought gold-workers, who continually have this metal in their hands, to be attentive to prevent the introduction of tin in their workfhops, and never to employ fuch compounds of gold as are fubject to break, or even to warp, while annealing? The expence of refining, which they would pay for depurating fuch compounds, would be of lefs confequence to them than the lofs of time required for the careful management of fuch gold contaminated by tin, even if they did fucceed in ufing it, and were not often forced to abandon, after much labour, a work nearly finifhed.

"If it be allowable (continues our author) to form conjectures on the caufe of the fracture of plates of gold containing tin, when fubjected to the annealing heat, it may be prefumed, fince tin very fpeedily melts, while gold requires a ftrong heat for its fufion, that the parts of the tin intermixed in a fort of proportional equality with thofe of the gold, tend to feparate by a fpeedy fufion and at a very gentle degree of heat; that they remain without confiftence between the parts of the gold, while the latter preferve the whole of their folidity, and do not lofe it even by the annealing heat: whence it feems, that the parts of the precious metal, when ignited among the coals, having no longer the folid connection formed by the tin, but, on the contrary, having an infinite number of fmall cavities occupied by particles of that metal in fufion, muft tend to difunion; whereas the fame accident does not take place in the pieces which have refifted the annealing, and have been laminated after cooling, becaufe the particles of tin have become folid by cooling, and have recovered their original ftate of union with the gold.

"This fracture of the compound does not take place with an alloy of gold and copper, for an oppofite reafon to that which has here been explained; namely, becaufe thefe two metals require nearly the fame heat for their fufion. The effect of annealing being therefore equal upon both, the metals, notwithftanding this treatment, preferve their natural confiftence, even tho' the heat be carried near the point of fufion."

Gold-Leaf. See *Gold-Leaf* (Encycl.) where a full account is given from Dr Lewis of the procefs of gold-beating. In that article, we have faid that gold-leaf ought to be prepared from the fineft gold; but Mr Nicholfon, who, in all probability, knows much more of the matter than the author from whom our account was copied, affures us that this is a miftake, and that pure gold is too ductile to be worked between the gold-beater's fkin. The neweft fkins will work the fineft gold, and make the thinneft leaf, becaufe they are the fmootheft. Old fkins, being rough or foul, require coarfer gold. The finer the gold, the more ductile; infomuch that pure gold, when driven out by the hammer, is too foft to force itfelf over the irregularities, but would pafs round them, and by that means become divided into narrow flips. The fineft gold for this purpofe has three grains of alloy in the ounce, and the coarfeft twelve grains. In general, the alloy is fix grains, or one eightieth part. That which is called pale gold contains three pennyweights of filver in the ounce. The alloy of leaf gold is filver, or copper, or both, and the colour is produced of various tints accordingly. Two ounces and two pennyweights of gold is delivered by the mafter to the workman, who, if extraordinarily fkilful, returns two thoufand leaves, or eighty books of gold, together with one ounce and

fix

fix pennyweights of waste cuttings. Hence one book weighs 4.8 grains; and as the leaves measure 3.3 inches in the side, the thickness of the leaf is one two hundred and eighty-two thousandth part of an inch.

The yellow metal called Dutch gold is fine brass. It is said to be made from copperplates, by cementation with calamine, without subsequent fusion. Its thickness, compared with that of leaf gold, proved as 19 to 4, and under equal surfaces it is considerably more than twice as heavy as the gold. *Nicholson's Journal, Vol. 1st.*

GOLD *River*, situated in Terra Firma, on the isthmus of Darien, southward of the river Santa Maria; affording much gold dust, from whence it has its name.—*Morse.*

GOLDEN *Island* lies at the mouth of the river or gulf of Darien, in the province of Terra Firma, in South America, N. lat. 9°. W. long. 77° 10′.—*ib.*

GOLDONI (Charles), was born at Venice in the year 1707. He gave early indications of his humourous character, as well as his invincible propensity to those studies which have rendered his name immortal. His father, perceiving that the darling amusement of his son was dramatic performances, had a small theatre erected in his own house, in which Goldoni, while yet an infant, amused himself with three or four of his companions, by acting comedies. Before he was sent to school, his genius prompted him to become an author. In the seventh and eighth years of his age, ere he had scarcely learned to read correctly, all his time was devoted to the perusing comic writers, among whom was *Cicognini*, a Florentine, little known in the dramatic commonwealth. After having well studied these, he ventured to sketch out the plan of a comedy, which needed more than one eye-witness of the greatest probity to verify its being the production of a child.

After having finished his grammatical studies at Venice, and his rhetorical studies at the Jesuit's college in Perugia, he was sent to a boarding-school at Rimini, to study philosophy. The impulse of nature, however, superseded with him the study of Aristotle's works, so much in vogue in those times. He frequented the theatres with uncommon curiosity; and passing gradually from the pit to the stage, entered into a familiar acquaintance with the actors. When the season of comic performances was over, and the actors were to remove to Chiozza, young Goldoni made his escape in their company. This was the first fault he committed, which, according to his own confession, drew a great many others after it. His father had intended him to be a physician like himself: the young man, however, was wholly averse to the study. He proposed afterwards to make him an advocate, and sent him to be a practitioner in Modena. An horrid ceremony of ecclesiastical jurisdiction, at which he was present, inspired him with a melancholy turn, and he determined to become a capuchin.

His father, perceiving the whimsical, inconstant humour of his son, feigned to second this proposal, and promised to go and present him to the guardian of the capuchins in Venice, in the hope that after some stay in that extensive and merry city, his melancholy fit would cease. The scheme succeeded; for the young man, indulging in all the fashionable dissipation of the place, was cured of his foolish resolution. It was however necessary for him to be settled in some employment; and he was prevailed upon by his mother, after the death of his father, to exercise the profession of a lawyer in Venice. By a sudden reverse of fortune he was compelled to quit at once both the bar and Venice. He then went to Milan, where he was employed by the resident of Venice in the capacity of secretary; where becoming acquainted with the manager of the theatre, he wrote a farce entitled *Il Gondoliere Veneziano*, the Venetian Gondolier, which was the first comic production of his that was performed and printed. Some time after Goldoni broke with the Venetian resident, and removed to Verona.

There was in this place, at that time, the company of comedians of the theatre of St Samuel of Venice, and among them the famous actor *Cosali*, an old acquaintance of Goldoni, who introduced him to the manager. He began therefore to work for the theatre, and became insensibly united to the company, for which he composed several pieces. Having removed along with them to Genoa, he was for the first time seized with an ardent passion for a lady, who soon afterwards became his wife. He returned with the company to Venice, where he displayed for the first time, the powers of his genius, and executed his plan of reforming the Italian stage. He wrote the *Momolo*, *Courtisan*, the *Squanderer*, and other pieces, which obtained universal admiration.

Feeling a strong inclination to reside some time in Tuscany, he repaired to Florence and Pisa, where he wrote *The Footman of Two Masters*, and *The Son of Harlequin lost and found again.* He returned to Venice, and set about executing more and more his favourite scheme of reform. He was now attached to the theatre of St Angelo, and employed himself in writing both for the company and for his own purposes. The constant toils he underwent in these engagements, impaired his health. He wrote, in the course of twelve months, sixteen new comedies, besides forty-two pieces for the theatre; among these many are considered as the best of his productions. The first edition of his works was published in 1753, in 10 vols. 8vo. As he wrote afterwards a great number of new pieces for the theatre at St Luca, a separate edition of these was published under the title of *The New Comic Theatre:* among these was the *Terence*, called by the author his *favourite*, and judged to be the master-piece of his works. He made another journey to Parma on the invitation of Duke Philip, and from thence he passed to Rome. He had composed 59 other pieces so late as the year 1761, five of which were designed for the particular use of Marque Albergati Capacelli, and consequently adapted to the theatre of a private company. Here ends the literary life of Goldoni in Italy.

Through the channel of the French Ambassador in Venice, he had received a letter from Mr Zenuzzi, the first actor in the Italian theatre at Paris, containing a proposal for an engagement of two years in that city. He accordingly repaired to Paris, where he found a select and numerous company of excellent performers in the Italian theatre. They were, however, chargeable with the same faults which he had corrected in Italy; and the French supported, and even applauded in the Italians, what they would have reprobated on their

Goldoni.

own stage. Goldoni wished to extend even to that country his plan of reformation, without considering the extreme difficulty of the undertaking. Scurrilities and jests, which are ever accompanied by actions, gestures and motions, are the same in all countries, and almost perfectly understood, even in a foreign tongue: while the beauties of sentiment and dialogue, and other things which lead to the understanding of characters and intrigues, require a familiar acquaintance with the tongue of the writer.

The first attempt of Goldoni towards his wished-for reform, was the piece called *The Father for Love*; and its bad success was a sufficient warning to him to desist from his undertaking. He continued, during the remainder of his engagement, to produce pieces agreeable to the general taste, and published twenty-four comedies; among which *The Love of Zelinda and Lindor* is reputed the best.

The term of two years being expired, Goldoni was preparing to return to Italy, when a lady, reader to the dauphiness, mother to the late king, introduced him at court, in the capacity of Italian master to the princesses, aunts to the king. He did not live in the court, but resorted there at each summons, in a post-chaise sent to him for the purpose. These journeys were the cause of a disorder in the eyes, which afflicted him the rest of his life; for being accustomed to read while in the chaise, he lost his sight on a sudden, and in spite of the most potent remedies, he could never afterwards recover it entirely. For about six months lodgings were provided him in the chateau of Versailles. The death, however, of the dauphin, changed the face of affairs. Goldoni lost his lodgings, and only, at the end of three years, received a bounty of 100 louis in a gold box, and the grant of a pension of four thousand livres a year. This settlement would not have been sufficient for him, if he had not gained, by other means, farther sums. He wrote now and then comedies for the theatres of Italy and Portugal; and, during these occupations, was desirous to shew to the French that he merited a high rank among their dramatic writers. For this purpose, he neglected nothing which could be of use to render himself master of the French language. He heard, spoke, and conversed so much in it, that, in his 62d year, he ventured to write a comedy in French, and to have it represented in the court theatre, on the occasion of the marriage of the king.

This piece was the *Bourru Bienfaisant*; and it met with so great success, that the author received a bounty of 150 louis from the king, another gratification from the performers, and considerable sums from the booksellers who published it. He published, soon after, another comedy in French, called *L'Avare Fastueux*. After the death of Louis XV. Goldoni was appointed Italian teacher to the Princess Clotilde, the present princess of Piedmont; and after her marriage he attended the late unfortunate Princess Elizabeth in the same capacity.

The approach of old age obliged him to quit Versailles, and to live in Paris, the air of which, less sharp, was better adapted to his constitution. The last work of Goldoni was *The Volponi*, written after his retirement from court; from which time he bade a lasting adieu to writing. Unfortunately for him he lived to see his pensions cut off at the revolution, like others, and he spent his last days in poverty and distress. He died in 1792, at a crisis when, according to the expression of a deputy in the Convention, the French nation was ready to repay him every debt of gratitude.

Goldsborough || Goniometry.

Goldoni is on a par with the greatest comic poets of modern times, with regard to dramatic talents, and is thought superior to them all with regard to the fertility of his genius. His works were printed at Leghorn in 1788—91, in 31 vols. 8vo. He has been generally called the Moliere of Italy; and Voltaire, in one of his letters to Marquis Albergati, styles him *The Painter of Nature*. Goldoni is one of those authors whose writings will be relished in the most remote countries, and by the latest posterity.

GOLDSBOROUGH, a post-town in Hancock county, District of Maine, containing 267 inhabitants. It was incorporated in 1789, is the south-easternmost town in the county. On the waters of its harbour is the town of Washington. It is 47 miles easterly of Penobscot, 188 south-east of Portland, and 330 north-east of Boston. N. lat. 44° 19′.—*Morse*.

GOLPHINGTON, the chief town of Washington county, Georgia, is situated near the head of Ogeeche river, about 26 miles east-south-east of Oconee town, 37 south-west of Augusta, and 50 north-west of Louisville.—*ib.*

GOMASHTEH, in the language of Bengal, one cent.

GONAIVES, a bay in the island of Hispaniola, south-eastward of Cape St Nicholas, in about 19° 33′ N. lat.—*Morse*.

GONAVE, an island in the bay of Leogane, in the western part of the island of St Domingo. It is 14¾ leagues long, and uniformly about 3 broad, except a very small part at each extremity. *Petite Gonave*, an isle about 2 miles each way, is separated from the south-east corner of the former, by a channel 3 miles wide. Gonave is 13½ leagues W. by N. W. of Port-au Prince; and its west point is 33½ leagues E. by N. of Cape Dame Marie.—*ib.*

Gonaives, a sea-port in the same island, at the head of a bay of its own name, on the north side of the bay of Leogane. The town is situated on the great road from Port de Paix to St Mark, 16 leagues south-east of the former and 15 N. by E. of the latter, N. lat. 19° 27′ W. long. from Paris 75° 2′ 30″.—*ib.*

GONIOMETRY, a method of measuring angles, so called by M. de Lagny, who gave several papers on this method in the Memoirs of the Royal Acad. anno 1724, 1725, 1729. M. de Lagny's method of goniometry consists in measuring the angles with a pair of compasses, and that without any scale whatever, except an undivided semicircle. Thus, having any angle drawn upon paper to be measured, produce one of the sides of the angle backwards behind the angular point; then with a pair of fine compasses describe a pretty large semicircle from the angular point as a centre, cutting the sides of the proposed angle, which will intercept a part of the semicircle. Take then this intercepted part very exactly between the points of the compasses, and turn them successively over upon the arc of the semicircle, to find how often it is contained in it, after which there is commonly some remainder: then take this remainder in the compasses, and, in like manner, find how often it is contained in the last of the integral parts of the

the firſt arc, with again ſome remainder: find, in like manner, how often this laſt remainder is contained in the former; and ſo on continually, till the remainder become too ſmall to be taken and applied as a meaſure. By this means he obtains a ſeries of quotients, or fractional parts, one of another, which being properly reduced into one fraction, give the ratio of the firſt arc to the ſemicircle, or of the propoſed angle to two right angles, or 180 degrees, and conſequently that angle itſelf in degrees and minutes.

We have given this account of goniometry from Dr Hutton, and frankly acknowledge that we had never thought of it till we peruſed his excellent Dictionary of Mathematics and Philoſophy. To have omitted the method when pointed out to us would have been wrong; though we miſtake much if mathematicians in general will not look upon it as a method of very little value.

GOOCHLAND, a county in Virginia, ſurrounded by Louiſa, Fluvanna, Henrico, Hanover, and Powhatan counties. It is about 40 miles long and 14 broad, and contains 9,053 inhabitants, including 4,656 ſlaves.—*ib.*

GOOD-HOPE, or CAPE OF GOOD HOPE, was taken by the Britiſh, on 17th Auguſt 1796 with very little difficulty. At this we need not be much ſurpriſed, if to the diſcontent which muſt have prevailed among the planters and townſmen with the new order of things, be added the manners of the people. M. Vaillant, who was at the Cape during the laſt war, when the garriſon expected to be every day attacked by a Britiſh ſquadron, and when the people were not abſolutely diſguſted with their own government, repreſents them, however, as rendered ſo completely frivolous by imitating the manners of their French allies, that though the place was ſtrongly fortified, it could hardly be expected to hold out long againſt a vigorous and well conducted ſiege.

"The females of the Cape (ſays he) when I ſaw them for the firſt time, had really excited my aſtoniſhment by their dreſs and their elegance; but I admired in them, above all, that modeſty and reſerve peculiar to the Dutch manners, which nothing as yet had corrupted.

"In the courſe of ſix months, a great change had taken place. It was no longer the French modes that they copied; it was a caricature of the French. Plumes, feathers, ribbons, and tawdry ornaments, heaped together without taſte on every head, gave to the pretties figures a grotesque air, which often provoked a ſmile when they appeared. This mania had extended to the neighbouring plantations, where the women could ſcarcely be known. A mode of dreſs entirely new was every where introduced; but ſo fantaſtical, that it would have been difficult to determine from what country it had been imported."

At that time a French and a Swiſs regiment were in the garriſon; and though the town was occupied only with warlike preparations, and though an attack from the Britiſh fleet was every moment expected, the French officers had already introduced a taſte for pleaſure. Employed in the morning at their exerciſe, the French ſoldiers in the evening acted plays. A part of the barracks was transformed into a theatre; and as women capable of performing female characters could not be found in the town, they aſſigned theſe parts to ſome of their comrades, whoſe youth, delicate features, and freſhneſs of complexion, ſeemed beſt calculated to favour the deception. Theſe heroines, of a new kind, heightened the curioſity of the ſpectators, and rendered the entertainment ſtill more lively and intereſting.

To add to the general pleaſure, ladies of the firſt rank conſidered it as incumbent on them to lend to the military actors and actreſſes, their laces, jewels, rich dreſſes, and moſt valuable ornaments. But ſome of them had cauſe to repent of their condeſcenſion; for it happened more than once that the Counteſs of Almaviva having left in pledge at the ſuttling houſe her borrowed decorations, the owner, to recover them, was obliged to diſcharge not only the bill due for brandy and tobacco, but all the other debts of the heroine.

During the intoxication and giddineſs occaſioned by theſe amuſements, Love alſo did not fail to act his part; and certain little intrigues were, from time to time, brought to light, which gave employment to the tongue of ſcandal, and introduced unhappineſs into families. Hymen, it is true, amidſt theſe adventures, ſometimes intervened to repair the follies of his brother, and many marriages, which reſtored every thing to order, were the reſult of his negotiations; but the complaints, though ſtifled, did not leſs exiſt. The watchfulneſs of the mother was alert. The huſband, by ſo much the more ſecretly irritated as he ſaw himſelf obliged to conceal his jealouſy, curſed in his heart both actors and theatre; while the matronly part of the community, leſs on the reſerve, declaimed with bitterneſs againſt the licentiouſneſs that prevailed, which they wholly imputed to this mode of theatrical entertainment. At laſt, to the great mortification of the young, but to the high ſatisfaction of the old women and huſbands, the theatre was on a ſudden ſhut up. The cauſe that effected this was altogether foreign to the complaints that were made, and of a nature that it was impoſſible to foreſee. Two of the French actors, who, it muſt be remembered, were officers in the army, thought proper to imitate the paper money of the company, and to put their forged notes in circulation. The forgery was detected, and traced to its authors; the two theatrical heroes were baniſhed from the Cape; and the Company, aſhamed of the adventure, dared neither ſeek others to ſupply the vacant places, nor reſume their ſtage entertainments.

Intoxicating as were theſe pleaſures, government meanwhile had not been inattentive to the danger which threatened the colony. As they daily expected to be attacked by the Britiſh fleet, they had increaſed the means of defence, and ordered different works and new fortifications to be conſtructed.

At firſt, the buſineſs was carried on with activity and ardour; becauſe the inhabitants, inſtigated by their private intereſt, which was then connected and involved with that of the public, had voluntarily offered their ſervices, and mingled with the workmen. Young and old, ſoldiers and magiſtrates, ſailors and planters, all ſolicited the honour of cooperating for the general good and common ſafety. To behold this heterogeneous multitude—ſome loaded with pickaxes, and ſome with ſpades, or other ſimilar implements—marching out in the morning from the town, and proceeding in high ſpirits to the new fortifications, was a ſight truly admirable.

But

But this patriotic fervour was of no long continuance. Under pretence of ſparing their ſtrength, and that they might not weary themſelves to no purpoſe, they ſoon cauſed their ſlaves to follow them with the tools and inſtruments. In a little time they contented themſelves with ſending their ſlaves only; and at laſt theſe ſubſtitutes themſelves, in imitation of their maſters, or perhaps by their ſecret orders, gave over going alſo. Their enthuſiaſm, in ſhort, from the firſt moment of its breaking out till the period when it was thus entirely cooled, had been the affair of ſomething leſs than a fortnight.

This taſte for frivolity which, almoſt twenty years ago, was introduced among the Dutch in Cape-town by their good friends the French, ſpread rapidly thro' the planters, who are thus deſcribed by M. Vaillant, who certainly had the beſt opportunities of knowing them.

The planters of the Cape may be divided into three claſſes; thoſe who reſide in the vicinity of the Cape, within a diſtance of five or ſix leagues; thoſe who live farther off in the interior parts of the colony; and laſtly, thoſe who, more diſtant ſtill, are found at the extremity of the frontiers among the Hottentots.

The firſt, who are opulent proprietors, and have handſome country houſes, may be likened to what was formerly called in France *petits ſeigneurs terriers*, and differ extremely from the other planters in eaſe and luxury, and particularly in their manners, which are haughty and diſdainful. Such is the reſult of wealth. The ſecond, ſimple, kind, hoſpitable, are cultivators, who live upon the fruits of their labour. Here we have an example of the good effects of mediocrity. The laſt, poor enough, yet too indolent to derive ſubſiſtence from the ſoil, have no other reſource than the produce of ſome cattle, which they feed as they can. Like the Beduin Arabs, they think much of the trouble of driving them from canton to canton, and from one paſturage to another. This wandering life prevents them from building any ſettled habitations. When their flocks oblige them to ſojourn for a while in the ſame place, they conſtruct, in haſte, a rude kind of hut, which they cover with matts, after the manner of the Hottentots, whoſe cuſtoms they have adopted, and from whom they in no reſpect differ, but in their complexion and features. And here the evil is, that there is no preciſe ſituation in ſocial life to which theſe miſerable beings belong.

Theſe ſluggiſh tribes are held in horror by their induſtrious neighbours, who dread their approach, and remove as far from them as they can; becauſe, having no property of their own, they ſteal without ſcruple that of others, and, when in want of paſturage for their cattle, conduct them ſecretly to the firſt cultivated piece of ground that comes in their way. They flatter themſelves they ſhall not be diſcovered, and they remain till every thing is devoured. If detected in their thefts, ſquabbles and contentions enſue, and afterwards a ſuit at law, in which recourſe is had to the magiſtrate, and which commonly terminates in making three men enemies, the robber, the perſon robbed, and the judge.

Nothing can be ſo mean and cringing as the conduct of the firſt deſcription of planters, when they have any thing to tranſact with the principal officers of the company, who may have ſome influence over their lot; and nothing ſo abſurdly vain and ſo ſuperlatively inſolent as their behaviour to perſons from whom they have nothing to hope and nothing to fear. Proud of their wealth, ſpoiled by reſiding near a town, from whence they have imbibed only a luxury that has corrupted, and vices that have degraded them, it is particularly towards ſtrangers that they exerciſe their ſurly and pitiful arrogance. Though neighbours to the planters who inhabit the interior of the country, you muſt not ſuppoſe they regard them as brethren; on the contrary, in the true ſpirit of contempt, they have given them the name of Rauw-boer, a word anſwering to the loweſt deſcription of clown. Accordingly, when theſe honeſt cultivators come to the town upon any kind of buſineſs, they never ſtop by the way at the houſes of the gentry of whom we are ſpeaking; they know too well the inſulting manner in which they would be received. One might ſuppoſe them to be two inimical nations, always at war, and of whom ſome individuals only met at diſtant intervals, upon buſineſs that related to their mutual intereſts.

What is the more diſguſting in the inſolence of theſe Africans is, that the majority of them are deſcended from that corrupt race of men, taken from priſons and hoſpitals, whom the Dutch company, deſirous of forming a ſettlement at the Cape, ſent thither to begin, at their riſk and peril, the population of the country. This ſhameful emigration, of which the period is not ſo remote but that many circumſtances of it are remembered, ought to render particularly modeſt thoſe who are in the moſt diſtant manner related to it. On the contrary, it is this very idea that moſt contributes to their arrogance; as if they flattered themſelves that, under the guiſe of ſupercilious manners, they could hide the abjectneſs of their origin. If a ſtranger arrives at the Cape with the deſign of remaining and ſettling there, they conceive him to be driven from his country by the ſame wretched circumſtances which formerly baniſhed their fathers, and they treat him with the moſt ſovereign contempt.

This melancholy failing is the more to be lamented, as the contagion has ſpread through almoſt every reſidence about the Cape, which is in reality a very charming canton. Embelliſhed by cultivation, by its numerous vineyards and pleaſant country houſes, it everywhere exhibits ſo varied and delicious a proſpect, that, were it occupied by other inhabitants, it would excite no ſenſations but thoſe of pleaſure.

As we advance into the country, the planters are a ſort of farmers; and conſtitute, by their manners, cuſtoms, and occupations, a claſs by themſelves, perfectly diſtinct from that we have been deſcribing. Situated farther from the Cape, and, of conſequence, not having the ſame opportunities for diſpoſing of their commodities, they are leſs rich than the firſt. We ſee among them none of thoſe agreeable country houſes, which, placed at different diſtances from the town, embelliſh the country as we paſs, and afford ſuch charming proſpects. Their habitation, which is about the ſize of a large coach-houſe, is covered with thatch, and divided into three rooms by means of two partitions, which reach only to a certain height. The middle apartment, in which is the entrance to the houſe, ſerves at once both as a parlour and eating room. It is there

Good-Hope.

that the family reſide during the day, and that they receive their tea and other viſitors. Of the two other rooms, one forms a chamber for the male children, and the other for the females, with the father and mother. At the back of the middle apartment is a farther room ſerving for a kitchen. The reſt of the building conſiſts of barns and ſtables.

Such is the diſtribution which is generally followed in the interior plantations of the colony; but nearer to the frontiers, where there does not prevail the ſame eaſe of circumſtances, the habitations are much leſs commodious. They are merely a barn, conſiſting of a ſingle room, without any diviſion, in which the whole family live together, without ſeparating, either day or night. They ſleep upon ſheep ſkins, which ſerve them alſo for covering.

The dreſs of theſe planters is ſimple and ruſtic. That of the men conſiſts of a check ſhirt, a waiſtcoat with ſleeves, a large pair of trowſers, and a hat half unlooped. The women have a petticoat, a jacket fitted to their ſhape, and a little round bonnet of muſlin. Unleſs upon extraordinary occaſions, neither ſex wear ſtockings. During a part of the year, the women even walk with their feet quite naked. The occupations of the men require that theirs ſhould have ſome covering; and this covering they make from a piece of the hide of an ox, applied and ſhaped to the foot ſoon after the animal is killed, and while the hide is yet freſh. Theſe ſandals are the only article of their dreſs which they make themſelves; the reſt is the buſineſs of the women, who cut out and prepare their whole wardrobe. Though the equipment we have mentioned conſtitute the every day dreſs of the planter, he has, however, a coat of handſome blue cloth, which he wears upon days of gala and ceremony. He has then alſo ſtockings and ſhoes, and is dreſſed exactly like an European. But this finery never makes its appearance but when he goes to the Cape; and then, indeed, is not put on till he arrives at the entrance of the town.

It is commonly in theſe journeys that they purchaſe ſuch things as they may want to refit their wardrobe. There is, at the Cape, as well as in Paris and London, a ſpecies of old-clothes-men, who deal in commodities of this ſort; and who, from their enormous profits, and the extortion they practiſe, they have obtained the name of *Capſe Smouſe*, or Cape Jews. Theſe traffickers contrive, at all times, to ſell their goods at a dear rate; but they vary their price in proportion as their ſtock is great or ſmall; of courſe they bear no fixed price; and the planter who comes from the deſert, and who can underſtand but little of this fluctuation, is ſure to be duped.

On the other hand, the regular ſhopkeeper, who knows the probity of theſe farmers, and how punctual they are in the payment of their debts, exerts every effort to prevail on them to open an account with him. He tempts them by the pretended cheap price and excellent quality of his ſtuffs, and offers to remit the payment till their next journey in the following year. It is ſeldom that theſe people, ſimple and unexperienced as they are, perceive the craft that is preſented to them under this guiſe of kindneſs and civility. If they ſuffer themſelves to be prevailed upon, they are ſhackled for life. Upon their return, there are new purchaſes to be made upon the ſame conditions; and thus, year after year, always in debt, always buying without prompt payment, they become the prey of an extortioner, who raiſes to himſelf a fortune out of their weakneſs.

It is true, theſe buyers, after being thus duped at the Cape, commonly return home only to make dupes of others. The cunning that has been employed to deceive them, they employ in their turn to tempt the Hottentots who are in their ſervice. The remnants of ſtuff, or the frippery garments which they bring back, are ſold to theſe unfortunate ſervants with ſo great a profit, that commonly the wages of a year are inadequate to the payment, and they find themſelves, like their maſters, in debt for the year that is to come. In the end, therefore, it is the poor Hottentot that pays for the extortion at the Cape.

Cuſtom has rendered the planters inſenſible to the want of fruit and pulſe, though the ſoil is admirably adapted to the cultivation of both. The facility with which they rear their cattle makes up for this privation, as their flocks afford them plenty of proviſion. The chief food is mutton; and their tables are loaded with ſuch profuſion as to diſguſt one at the ſight.

From this mode of living, cattle are in the colonies, as in other places, not only a uſeful object, but an article of the firſt neceſſity. The planter undertakes himſelf the care of watching over his flocks. Every evening, when they return from the field, he ſtands at his door, with a ſtick in his hand, and counts them over one by one, in order to be ſure that none of them are miſſing.

People who have no other employment than a little agriculture, and the ſuperintendance of a flock, muſt have long intervals of idleneſs. It is thus with the planters, particularly thoſe who live in the interior parts of the country, and who being unable, on account of their diſtance from the Cape, to diſpoſe of their corn, never raiſe more than is ſufficient for their own conſumption. From the profound inaction in which they live, one would ſuppoſe their ſupreme felicity to conſiſt in doing nothing. They ſometimes, however, viſit each other; and upon theſe occaſions the day is ſpent in ſmoking, and drinking tea, and in telling, or liſtening to tales of romance, that are equal neither in merit nor morality to the ſtory of Blue-beard.

As every man always carries with him, wherever he goes, both a pipe, and a tobacco pouch made of the ſkin of the ſea-calf, he is ſure in theſe viſits to have one ſource of amuſement. When any one of the company is deſirous of lighting his pipe, he takes out his pouch, and, having filled, paſſes it to the reſt. This is a civility that is never omitted. However numerous may be the party, every body ſmokes: the conſequence of which is a cloud, that, riſing at firſt to the upper part of the room, increaſes, by degrees, till it fills the whole houſe, and becomes at laſt ſo thick, that it is impoſſible for the ſmokers to ſee one another.

When a ſtranger travelling through the country is received by the maſter of a houſe, he inſtantly becomes a member of the family. Accuſtomed to a domeſtic life, the planters delight in the ties of affinity, and conſider in the light of a relative every perſon whom they love. Upon entering a houſe, the form of ſalutation is, to ſhake hands firſt with the maſter, and then with

with every male person in the company arrived at years of maturity. If there happens to be any one whom we do not like, the hand is refused to him; and this refusal, of so common a testimony of friendship, is looked upon as a formal declaration that the visitor considers him as his enemy. It is not the same with the females in the company. They are all embraced one after another, and to make an exception would be a signal affront. Old or young, all must be kissed. It is a benefice with the duties attached to it.

At whatever time of the day you enter the house of a planter, you are sure to find the kettle and tea-things upon the table. This practice is universal. The inhabitants never drink pure water. If a stranger presents himself, it is tea they offer him for refreshment. This is their common liquor in the interval of meals, and in one season of the year, when it often happens that they have neither beer nor wine, is their only beverage.

If a stranger arrives at dinner-time before the cloth is taken away, he shakes hands, embraces, and immediately seats himself at the table. If he wishes to pass the night, he stays without ceremony, smokes, drinks tea, asks the news, gives them all he knows in his turn; and the next day, the kissing and shaking hands being repeated, he goes on his way, to perform elsewhere the same ceremony. To offer money on these occasions would be regarded as an insult.

These particulars of a people, whose condition it is to be hoped that the generosity of the British character, and the mildness of the British government, will gradually meliorate, cannot but be acceptable to many of our readers. We shall, therefore, make no apology for the length of this article.

GOOSE *Creek*, a river which falls into Potowmac river, about a mile south-east of Thorpe, in Fairfax county, Virginia.—*Morse*.

GOOSEBERRY *Mountain*, in New-York State, lies on the west bank of Hudson's river, about 4 miles south of Fort George.—*ib*.

GOOSEBERRY *Islands* and *Rocks*, on the coast of Essex county, Massachusetts, have been the occasion of the loss of many valuable vessels. To prevent such accidents in future, seamen may attend to the following particular information, which is here inserted for their benefit. The north part of Gooseberry great rock with the north of Cat Island, bears S. 54. W. from the beacon on Baker's Island. The western Gooseberry S. 41. W. the distance nearly three fourths of a mile. The northern part of the western Gooseberry is viewed from the beacon over the point of land running out from it. The eastern Gooseberry bears S. 26. W. and it is shoal as far as the western breaker. The eastern breaker lies S. 35. E. and the western breaker S. 29. E. The eastern breaker is about the same distance from the beacon, as the western Gooseberry, but the eastern Gooseberry falls within that distance. Satan appears S. 32. W. and halfway rock S. 3. W. at the distance of $2\frac{1}{2}$ miles. The inner part of Cat Island is above 2 miles from the beacon, and with the beacon to the southward the Gooseberry rock bears only 12 minutes. The western dry breaker extends from 28 to 32; and the eastern from 31 to 32. Half-way rock with the beacon from Cat Island is 65 to the southward.—*ib*.

GORHAM, a township in Cumberland county, Maine, on the north-east side of Saco river, 15 miles from Pepperelborough at the mouth of the river, and 130 miles N. by E. of Boston. It was incorporated in 1764, and contains 2 244 inhabitants.—*ib*.

GOSHEN, a township in Hampshire county, Massachusetts, between Cummington and Conway, 14 miles north of Northampton, and 112 W. by N. of Boston. It was incorporated in 1781, and contains 681 inhabitants.—*ib*.

GOSHEN, a township in Addison county, Vermont, adjoining to Salisbury on the west, and 21 miles N. E. by N. of Mount Independence.—*ib*.

GOSHEN, a township in Chester county, Pennsylvania.—*ib*.

GOSHEN, a town in Litchfield county, Connecticut, famous for the production of excellent cheese. It is 7 miles N. by N. W. of Litchfield, and 50 northward of New-Haven.—*ib*.

GOSHEN, the most considerable town in Orange county, New-York, about 58 miles north of New-York city, 20 W. by S. of New-Windsor, and 30 W. by S. of Fish-Kill. This town is pleasantly situated, containing about 60 or 70 houses, an academy, court-house, gaol, and Presbyterian church. The township contains 2,448 inhabitants; of whom 316 are electors. —*ib*.

GOSHGOSHINK, a Moravian settlement in Pennsylvania, situated on Alleghany river, about 15 miles above Venango, or Fort Franklin.—*ib*.

GOSPORT, formerly called *Appledore*, a fishing town on Star Island, one of the isles of Shoals, belonging to Rockingham county, New-Hampshire, containing 93 inhabitants. It lies about 12 miles E. S. E. of Piscataqua harbour.—*ib*.

GOTHIC ARCHITECTURE, See *Gothic* ARCHITECTURE in this *Supplement*, and ROOF, *Encyclopædia*.

GOUVERNANTE, the Spanish name of a plant which the Indians of California use in decoction as a sudorific drink for the cure of the venereal disease. It is thus described in the third volume (English translation) of Peyrouse's Voyage round the world.

Calyx quadrifid, egg shaped, of the same size with the corolla; placed beneath the fruit, deciduous. Corolla polypetalous; petals four, small, entire, egg shaped, fixed upon the receptacle. Stamina, eight, fixed to the receptacle, of the same length as the corolla: threads channelled, concave on the one side, and convex on the other; wings veiled, antheræ simple. Pistil, germ oblong, covered, with five angles, and five cells; seeds oblong; pericarpium covered with fine hairs.

This plant is a shrub of middle size; the branches are angular and knotty, and covered with an adhesive varnish; the lateral branches are alternate, and placed very near to each other: the leaves are small, petiolated, bilobed, opposite, smooth on the upper side, the under side indistinctly veined; the blossoms are axillary, sometimes terminating, pedunculated, solitary, but sometimes in pairs.

From this description, the gouvernante appears to be a new species of *daphne*.

GRACIAS A DIOS, a town belonging to the province of Honduras, or Comaiagua, and audience of Guatimala. It is situated at the mouth of a river upon a rocky mountain, which has some gold mines in its neighbourhood. It was built the same year as was Vallidolid, the capital, (from which it lies about 27 leagues to the west) for the security of the miners. Also a cape on this coast discovered by Columbus, N. lat. 14° 36′ W. long. 84° 12′.—*Morse.*

GRAFTON *County*, in New-Hampshire, is bounded north by Canada; south by the counties of Strafford, Hillsborough, and Cheshire; west by the State of Vermont, and east by the District of Maine. It comprehends nearly as much territory as all the other four counties, but is by no means so thickly settled. It it divided into 50 townships, and 17 locations, and contains 13,472 inhabitants, of whom 21 are slaves. The increase of population since the enumeration of 1790 has been great.—*ib.*

GRAFTON, a township in the county of its name in New-Hampshire, 13 miles S. E. of Dartmouth college and 19 S. W. of Plymouth. It was incorporated in 1778, and contains 403 inhabitants. *Lapis specularis*, commonly called ising-glass, of the best quality, is found in this town, in a mountain about 20 miles eastward of Dartmouth college. It is found adhering to the rocks of white or yellow quartz, and lying in laminæ, like sheets of paper. It is found in other places in the State in smaller pieces.—*ib.*

GRAFTON, the *Hassanamisco* of the Indians, a township in Worcester county, Massachusetts, containing 900 inhabitants; 40 miles S. W. of Boston, 8 easterly of Worcester, and 34 N. W. of Providence.—*ib.*

GRAINGER, FORT, stands on the N. side of the mouth of Holston river in Tennessee.—*ib.*

GRAINGER, the name given to a new county, in the district of Hamilton, State of Tennessee, formed of parts of the counties of Knox, Jefferson and Hawkins, and called after the maiden name of the Lady of Gov. William Blount.—*ib.*

GRANBY, a township in Essex county, Vermont. —*ib.*

GRANBY, a township in Hampshire county, Massachusetts, E. of South-Hadley, about 90 miles westerly of Boston; was incorporated in 1768, and contains 596 inhabitants.—*ib.*

GRANBY, a township in Hartford county, Connecticut, on the line which separates Connecticut from Massachusetts. It was formerly a part of Symsbury, and is 18 miles north of Hartford.—*ib.*

GRANBY, a small town on the Congaree, in S. Carolina, about 2 miles below the junction of Broad and Saluda rivers. Here a curious bridge has been built, whose arches are supported by wooden pillars, strongly secured in iron work, fixed in the solid rock. Its height is 40 feet above the level of the water. The centre arch is upwards of 100 feet in the clear, to give a passage to large trees which are always brought down by the floods. The ingenious architect has the toll secured to him by the Legislature for 100 years. —*ib.*

GRANDE RIVIERE, a settlement in a hilly tract of the island of St Domingo, 6½ leagues south-west of Fort Dauphin, and 4¾ leagues N. by E. of St Raphael, in the Spanish part of the island, N. lat. 19° 34′, W. long. from Paris 74° 30′.—Also the name of a small river, in the same island, which rises at Limonade, and empties into the sea at Qr Morin, 5 leagues east of Cape François.—*ib.*

GRAND *Fathers*, several large detached mountains in the south-east corner of Tennessee, in which are the head waters of French, Broad and Catabi rivers.—*ib.*

GRAND *Isles*, are two large islands in Lake Champlain; each about 8 or 10 miles long, and each forms a township belonging to Vermont.—*ib.*

GRAND *Island*, at the mouth of Lake Ontario, is within the British territories, having Roebuck and Forest islands on the south-west, and the Thousand Isles on the north-east. It is 20 miles in length, and its greatest breadth is 4 miles.—*ib.*

GRAND *Island*, in Lake Superior, lies on the north side of the lake.—*ib.*

GRAND *Island*, in Niagara river, is about 6 miles long and 3 broad. The south end is 4 miles north of Fort Erie; and its northern extremity 3 miles south of Fort Slusher, and nearly 14 south of Niagara fort.—*ib.*

GRAND *Lake*, in the province of New Brunswick, near the river St John's, is said to be 30 miles in length, 8 or 10 in breadth, and in some places 40 fathoms deep.—*ib.*

GRAND MANAN *Island*, lies 6 miles S. by S. E. of Campo-Bello Island, in the Atlantic Ocean, opposite to Passamaquoddy Bay, on the eastern border of the United States.—*ib.*

GRAND *River* runs a north-west course into Lake Erie, 20 miles below the Forks, 80 miles south-west of Presque Isle.—*ib.*

GRANGE, *Cape La*, or *Cape Monte Christ*, on the north side of the island of St Domingo. It is a high hill, in the form of a tent, and may be seen by the naked eye at Cape François, from which it is 14 leagues E. by N. A strip of land joins it to the territory of Monte Christ; so that at a distance it seems to be an island. The cruisers from Jamaica often lie off here. This cape lies in lat. 19° 54′ 30″ N. and long. 74° 9′ 30″ W. from Paris; and with Point de Dunes forms the mouth of the bay of Monte Christ. —*ib.*

GRANVILLE, a fine township in Annapolis county, Nova-Scotia. It lies on the north side of Annapolis river, on the Bay of Fundy, and is 30 miles in length; first settled from New-England.—*ib.*

GRANVILLE, a township in Hampshire county, Massachusetts, about 14 miles west of Springfield. It was incorporated in 1754, and contains 1979 inhabitants. —*ib.*

GRANVILLE, a township in Washington county, New-York, containing 2240 inhabitants, of whom 422 are electors.—*ib.*

GRANVILLE *County*, in Hillsborough district in North-Carolina, has the State of Virginia north, and contains 10,982 inhabitants, of whom 4163 are slaves. Chief town, Williamsburg.—*ib.*

GRANVILLE, a flourishing town in Kentucky.—*ib.*

GRAVE CREEK, on the Ohio, 12 miles down the river from Wheeling. Here is a mound of earth, plainly the work of art, called an Indian grave. It is of a conical form, in height about 80 feet. It ascends in an angle of about 80°. The diameter at the top is about 60 feet; the margin enclosing a regular concave, sunk about 4 feet in the centre. Near the top stands an oak, about 3 feet in diameter. It is said the Indians have no tradition what nation ever buried their dead in this manner. On examination, these mounds have

have been found to contain a chalky substance, supposed to be bones of the human kind.—*ib.*

GRAVESEND, Port of, is situated on the south-western side of the island of Jamaica, in a large bay. It has two channels; the Leeward and the Main Channel, and affords good anchorage for large vessels.—*ib.*

Gravesend, a small village in King's county, Long-Island, New-York, 7 miles N by E. of the city. The township of its name contains 426 inhabitants.—*ib.*

GRAVIMETER, the name given by citizen Guyton (Morveau) to an instrument of glass, constructed in all respects on the principle of Nicholson's Hydrometer, described in the article Hydrostatics, n° 18 (*Encycl.*) It is therefore needless to give a description of this instrument here; as every artist in glass, who has seen Nicholson's Hydrometer, or understands our description of it, may construct the gravimeter of Morveau; and every man who has made himself master of our article Specific *Gravity*, may apply the gravimeter to every purpose to which it is applicable. It may just be proper to observe, that Morveau, having at first loaded the small scale or bason G (Plate 240, fig. 9. *Encycl.*) with a bulb of glass containing a sufficient quantity of mercury, found it expedient afterwards to substitute in the place of this bulb a small mass of solid glass, brought to the proper form and weight by grinding. For a minute account of this instrument, if any of our readers can be supposed to require a minute account of it, we must refer to the third number of Nicholson's *Journal of Philosophy, Chemistry*, and the *Arts*.

GRAY, a post-town in the District of Maine, in Cumberland county, 15 miles N. by W. of Portland. The township was incorporated in 1778, and contains 577 inhabitants.—*Morse.*

GREAT BARRINGTON, a township in the south-western part of the State of Massachusetts, in Berkshire county, lying south of Stockbridge, 150 miles west of Boston, and 26 E. by S. of Hudson city, New-York.—*ib.*

Great Famine, a river in New-York which rises in the mountains near the source of Oneida river, and flows N. W. by W. to Lake Ontario. Its mouth is 10 miles south-westerly from the mouth of Black river.—*ib.*

Great Kanhaway, a large river which flows through the eastern bank of the Ohio in 39° 5′ N. lat. nearly 500 yards wide at its mouth. The current is gentle for about 10 or 12 miles, when it becomes considerably rapid for upwards of 60 miles farther, where you meet with the first falls, when it becomes impossible to navigate it from the great number of its cataracts.—*ib.*

Great Swamp, between Northampton and Lucern counties, in Pennsylvania. This swamp, on examination and survey, is found to be good farm land; thickly covered with beach and sugar maple.—*ib.*

Great Ridge, one of the ridges of the Alleghany Mountains, which separates the waters of the Savannah and Alatamaha.

At the south-east promontory of the Great Ridge is that extraordinary place called Buffaloe Lick, distant about 80 miles from Augusta. It occupies several acres of ground. A large cane swamp and meadows, forming an immense plain, lie south-east from it; in this swamp Mr Bartram thinks the branches of the Great Ogeeche take their rise. The Lick is nearly level, and lies between the head of the cane swamp, and the ascent of the Ridge. The earth, from the superficies to an unknown depth, is an almost white or cinerous coloured, tenacious, fattish clay, which all kinds of cattle lick into great caves, pursuing the delicious vein. Mr Bartram could not discover any thing saline in its taste, but an insipid sweetness. Horned cattle, horses, and deer, are immoderately fond of it; insomuch that their excrement, which almost totally covers the earth to some distance round this place, appears to be perfect clay; which when dried by the sun and air, is almost as hard as brick.—*ib.*

Great Springs, is an amazing fountain of transparent, cool water, situated near the road, about mid-way between Augusta and Savannah. It breaks suddenly out of the earth at the basis of a moderately elevated hill or bank, forming at once a bason near 20 yards over, ascending through a horizontal bed of soft rocks, chiefly a testaceous concretion of broken, entire, and pulverized sea-shells, sand, &c. constituting a coarse kind of lime-stone. The ebullition is copious, active, and continual, over the ragged apertures in the rocks, which lie seven or eight feet below, swelling the surface considerably, immediately above it; the waters descend swiftly from the fountain, forming at once a large brook, six or eight yards over, and five or six feet deep. There are multitudes of fish in the fountain of various tribes; chiefly the several species of bream, trout, catfish, and garr, which are beheld continually ascending and descending through the rocky apertures. Bartram, from whose travels the above is taken, observes, that he crossed no stream or brook of water within 12 or 15 miles of this fountain, but had in view vast savannahs, swamps, and cane meadows, which he conjectures are the reservoirs which feed this delightful grotto.—*ib.*

GREEN, though one of the seven original or prismatic colours, is among dyers a compound of blue and yellow. Of the European methods of dyeing green, and of the principles on which these methods are founded, a sufficient account will be found in the *Encyclopædia*, under the articles Colour-*making* and Dyeing, and, in this *Supplement*, under *Animal and Vegetable* Substances; but it may be worth while, in this place, to insert the method practised at Astracan, in giving to cotton yarn that beautiful green colour for which the oriental cotton is so justly admired.

The principal dye is the blue, which is employed both for cotton and silk. To prepare it, the indigo or blue dye-stuff is finely pounded, and dissolved in water by a gentle heat in large earthen jars, seven of which stand in brick-work over the fire-place, at the distance of about an ell and a half from each other. About two pounds are put into each vessel. Five pounds of soda finely pounded, together with two pounds of pure lime and one pound of clarified honey, are added to each; when these ingredients have been well mixed, the fire is strengthened; and when the whole begins to boil, the dye is stirred carefully round in all the vessels, that every thing may be completely dissolved and mixed. After the first boiling the fire

Green.

is ſlackened, and the dye is ſuffered to ſtand over a gentle heat, while it is continually ſtirred round: this is continued even after the furnace is cooled, till a thick ſcum ariſes in the neck of each jar, and ſoon after diſappears. The dye is then allowed to ſtand two days, until the whole is incorporated, and the dye thickens.

The dyers aſſert, that with this dye they can produce three ſhades of blue, and that, as the dyeing particles gradually diminiſh, they can die alſo a green colour by the addition of yellow.

When a manufacturer gives cotton yarn to a blue dyer, he firſt boils it at home in a ley of ſoda *(kalakar)*, then dries it, waſhes it, and dries it again. The blue dyer lays this yarn to ſteep in pure water, preſſes out the ſuperfluous water with the hands, and then immediately begins to dip it in the blue jar, often wringing it till it is completely penetrated by the dye. This firſt tint is generally given to yarn in ſuch jars as have had their colouring matter partly exhauſted. It is then dried, rinſed, and again dried: after which, it is put into the freſh blue dye, properly ſaturated; and, after the colour has been ſufficiently heightened, it is dried for the laſt time.

For a yellow dye, the dyers of Aſtracan employ partly ſaw-wort, brought from Ruſſia, and partly the leaves of the *kiſtar belge*, or *ſumach*. The proceſs is as follows: The yarn is firſt boiled for an hour in a ſtrong ley of ſoda; it is then dried, afterwards rinſed and laid wet to ſteep for twelve hours in a ſolution of alum with warm water. When it has been dried in the air, it is laid to ſoak ſeveral times in troughs with the dye which has been boiled thick in kettles from the abovementioned plants, till it has acquired the wiſhed-for colour, care being taken to dry it each time it is ſoaked. It is then rinſed in running water, and dried for the laſt time.

On this yellow colour a green is often dyed. After the yarn has been dyed yellow, it is given out to the blue dyer, who immediately dips it in the blue jars, the dye of which has been already partly exhauſted: and if the green colour is not then ſufficiently high, the operation is repeated, the yarn being dried each time. See *Neue Nordiſche Beytrage*, by Profeſſor Pallas; or *Philoſophical Magazine*, nº 2.

GREEN, a townſhip in Franklin county, Pennſylvania.—Alſo a townſhip in Waſhington county in the ſame State.—*Morse.*

GREEN, a poſt-town in Lincoln county, in the Diſtrict of Maine, ſituated on the eaſt ſide of Androſcoggin river, 31 miles W. by S. of Pittſton, 39 north of Portland, and 164 N. by E. of Boſton, containing 639 inhabitants.—*ib.*

GREEN, a navigable river of Kentucky, which riſes in Mercer county, has a gentle current, and is navigable nearly 150 miles. Its courſe is generally weſt; and at its confluence with the Ohio is upwards of 200 yards wide. Between the mouth of Green river and Salt river, a diſtance of nearly 200 miles, the land upon the banks of the Ohio is generally fertile and rich; but, leaving its banks, you fall into the plain country, which is conſidered as little better than barren land. On this river are a number of Salt ſprings or licks. There are three ſprings or ponds of bitumen near this river, which do not form a ſtream, but empty themſelves into a common reſervoir, and when uſed in lamps, anſwers all the purpoſes of the beſt oil. Vaſt quantities of nitre are found in the caves on its banks; and many of the ſettlers manufacture their own gunpowder.—*ib.*

Green ! Greencaſtle.

GREEN BAY, or *Puan Bay*, a ſouth weſtern branch of Lake Michigan.—*ib.*

GREEN, a ſmall river which riſes in the town of Marlborough in Vermont, and falls into Connecticut river above Deerfield, in Maſſachuſetts.—*ib.*

GREEN BRIAR, a large and fertile county of Virginia, ſurrounded by Bath, Randolph, Harriſon, Kanhaway, Botetourt, and Montgomery counties. It is about 100 miles long and 45 broad; and together with Kanhaway county, which was formerly a part of it, contains 6,015 inhabitants, including 319 ſlaves. There is a large cave on Rich Creek in this county, the earth at the bottom of which is ſtrongly impregnated with ſulphur. Many ſuch are to be found on Green Briar river. The chief town is Lewiſburg. At *Green Briar* court-houſe is a poſt-office, 30 miles W. by S. of Sweet Springs, and 103 weſt of Staunton.—*ib.*

GREEN BRIAR *River* runs a S. W. courſe, and falls into the eaſtern ſide of the Great Kanhaway, at the place where that river breaks through the Laurel Ridge, and oppoſite to the mouth of New river, in N. lat. 38.—*ib.*

GREEN MOUNTAINS, a range of mountains extending N. N. E. to S. S. W. and dividing the waters which flow eaſterly into Connecticut river, from thoſe which fall weſterly into Lake Champlain, Lake George, and Hudſon's river. The aſcent from the eaſt to the top of the Green Mountain in Vermont, is much eaſier than from the weſt, till you get to Onion river, where the mountain terminates. The height of land is generally from 20 to 30 miles from the river, and about the ſame diſtance from the New-York line. The natural growth upon this mountain, is hemlock, pine, ſpruce, and other evergreens; hence it has always a green appearance, and on this account has obtained the deſcriptive name of *Ver Mons*, Green Mountain. On ſome parts of this mountain ſnow lies till May, and ſometimes till June. The chain extends through Maſſachuſetts and Connecticut, and terminates in New-Haven. Kellington Peak, the higheſt of theſe mountains, is about 3,454 feet above the level of the ocean.—*ib.*

GREEN *Woods*, a vaſt foreſt of ſtately pines in Litchfield county, Connecticut, which cover the face of a part of that county. Theſe are cloathed in green bearded moſs, which being pendant from the boughs, ſcreens many of the trees from the eyes, and gives to the whole a gloomy, wild, and whimſical appearance. —*ib.*

GREENBURGH, a townſhip in Weſtcheſter county, New-York, containing 1400 inhabitants, of whom 122 are ſlaves, and 164 are electors.—*ib.*

GREENCASTLE, a town in Franklin county, Pennſylvania, ſituated near the Conegocheague creek. Here are about 80 houſes, 2 German churches, and a Preſbyterian church. It is 11 miles S. by W. of Chamberſburg, and 156 W. by S. of Philadelphia.—*ib.*

Greene, a county in Kentucky, extending from Ohio river on the north, to Tennessee State on the south, and bordering west on the Mississippi river, and east upon Hardin and Jefferson counties.—*ib.*

Greene, a county in Washington district in the State of Tennessee, having 7,741 inhabitants, of whom 454 are slaves. Greenville college has been established by law in this county. It is situated between two small northern branches of Nolachucky river, about 15 miles N. W. by W. of Jonesborough, and 54 east of the mouth of French Broad river.—*ib.*

Greene, a township in Tioga county, New-York, on the east side of Chenengo river.—*ib.*

Greene, a county in the upper district of Georgia, bounded west by the upper part of Oconee river, east by Wilkes county, and south by that of Washington. It contains 5,405 inhabitants, including 1,377 slaves. Chief town, Greensborough.—*ib.*

GREENEVILLE, a post-town, and the chief town of Pitt county, North-Carolina; situated on the south bank of Tar river, distant from Ocreecok Inlet 110 miles. It contains about 50 houses, a court-house and gaol; also a seminary of learning, called the Pitt Academy. It is 23 miles from Washington and 25 miles from Tarborough.—*ib.*

Greeneville, a small post-town in Greene county, in the State of Tennessee, situated on the west side of the north-easternmost branch of Nolachucky river, about six miles N. by E. of Greenville college, 26 miles north-west of Jonesborough, 75 east of Knoxville, and 653 south-west of Philadelphia.—*ib.*

GREENFIELD, a handsome flourishing town in Hampshire county, Massachusetts, about 4 miles north of Deerfield, and 114 W. by N. of Boston. The township lies on the west bank of Connecticut river, was incorporated in 1753, and contains 1,498 inhabitants. A company was incorporated in 1796 to build a bridge over Connecticut river, to connect this town with Montague.—*ib.*

Greenfield, a township in Saratoga county, New-York; 380 of the inhabitants are electors.—*ib.*

GREENLAND, a town in Rockingham county, New-Hampshire, in the vicinity of the ocean, 5 miles southerly from Portsmouth. It was incorporated in 1713, and contains 634 inhabitants.—*ib.*

GREENSBOROUGH, a post-town, and chief town of Greene county, Georgia, 30 miles from Lexington, and 78 W. by S from Augusta.—*ib.*

Greensborough, a thriving village in Caroline county, Maryland; on the west side of Choptank Creek, about seven miles north of Danton, and 22 miles S. E. by S. of Chester.—*ib.*

Greensborough, a new township in Orleans county in Vermont. It adjoins to Minden on the north-west, and Wheelock on the south-east, and contains only 19 inhabitants.—*ib.*

GREENSBURG, a post town, and the capital of Westmoreland county, Pennsylvania. It is a neat pretty town, situated on a branch of Sewickly Creek, which empties into Youghiogany river. Here are 100 dwelling houses, a German Calvinist church, a brick court house, and a stone gaol. It is 31 miles S. E. by E. of Pittsburg, and 270 W. by N. of Philadelphia. —*ib.*

GREENSVILLE, a county of Virginia, encompassed by Brunswick, Southampton, and Sussex counties, on the west, north, and east, and by the State of North-Carolina on the south. It is about 24 miles long, and 20 broad, and contains 6,362 inhabitants, of whom 3,620 are slaves.—*ib.*

GREENVILLE *Court-House*, in Virginia, stands on Kick's Ford, 25 miles from Southampton, and 61 from Norfolk.—*ib.*

Greenville, a county in Washington district, S. Carolina; situated in the N. W. corner of the State; bounded east by Spartanburg county, in Pinckney district; south, by Pendleton; west, by the State of Georgia, and that tract of country which the State of South-Carolina ceded to the United States; and north, by the State of North Carolina. It contains 6,503 inhabitants, of whom 606 are slaves. Taxes £192 : 6 : 8. The lands are mountainous and hilly, and well watered, and the climate healthy and agreeable. —*ib.*

Greenville, a post-town of South-Carolina, and chief town of Cheraws district; situated on the west side of Great Pedee river, in Darlington county. It contains about 30 houses, a court-house, gaol, and academy. It is 55 miles E. N. E. of Camden, 90 N. E. by E. of Columbia, 135 N. by E. of Charleston.—*ib.*

Greenville, a fort and settlement in the N. W. Territory, on the south side of a north-western branch of the Great Miami, six miles north-west of Fort Jefferson on the same branch, and about 23 miles south-east of Fort Recovery. It is a picketed fort, with bastions at each angle, and capacious enough to accommodate 2,000 men. Here the American legion had their head-quarters in the late war with the Indians. It was established by the late Maj. Gen. A. Wayne in 1793, and here he concluded a treaty of peace with the Indian nations, on the 3d of August, 1795.—*ib.*

Greenville Bay, or *La Bay*, a town and port of entry on the east or windward side of the island of Granada. It has about 60 dwelling-houses, a church, and several rich stores of India and European goods, and plantation utensils. The situation is low, and rather unhealthy.—*ib.*

GREENWICH, a township in Hampshire county, Massachusetts, incorporated in 1754, contains 1045 inhabitants. It is 20 miles easterly of Northampton, and 75 westerly of Boston.—*ib.*

Greenwich, a township, the second in rank in Gloucester county, New-Jersey, situated on the east bank of Delaware river, opposite to Fort Mifflin, 3 miles N. by E. of Woodbury, and 6 south-east of Philadelphia.—*ib.*

Greenwich, a township in Sussex county, New-Jersey, on the east side of Delaware river, in a mountainous country, about 5 miles north-easterly of Easton, in Pennsylvania, and 31 south-west of Newton, the shire town. It contains 2,035 inhabitants, of whom 64 are slaves.—*ib.*

Greenwich, a town in Cumberland county, New-Jersey, on the north-west bank of Cohanzy creek, about 3 miles from its mouth in Delaware bay. Here are about 80 houses, and a Friend's meeting-house. It is 15 miles south-easterly of Salem, and 66 S. by W. of Philadelphia.—*ib.*

Greenwich, a maritime township in Fairfield county,

ty,

ty, Connecticut, and the south-westernmost of the State, lies about 50 miles west of New-Haven, and 40 east of New-York city. Its sea-coast on Long Island Sound, and that of the township of Stamford on the eastward, has a number of isles and rocks bordering the inlets of the sea and mouths of the creeks. Byram river passes through this town, the largest of the small streams which water it, and only noticeable as forming part of the line between Connecticut and New-York.

This tract was purchased of the native Indians in 1640, and settled under the government of the New Netherlands (now New-York) and was incorporated by Peter Stuyvesant in 1665, who was then governor of the New Netherlands. This town falling within the bounds of Connecticut, was afterwards granted to eight persons by that colony.—*ib.*

GREENWOOD, a township in Cumberland county, Pennsylvania. Also, a township in Mifflin county in the same State.—*ib.*

GREGORIA, St, a town of New-Mexico, situated on the east side of Rio Bravo, a few leagues north of St Antonio.—*ib.*

GREGORY (David), was a son of the Rev. John Gregory, minister of Drumoak, in the county of Aberdeen, and elder brother to Mr James Gregory, the inventor of the most common reflecting telescope. He was born about the year 1627 or 1628; and though he possessed all the genius of the other branches of his family, he was educated by his father for trade, and served an apprenticeship to a mercantile house in Holland. Having a stronger passion, however, for knowledge than for money, he abandoned trade in 1655; and returning to his own country, he succeeded, upon the death of an elder brother, to the estate of Kinardie, situated about forty miles north from Aberdeen, where he lived many years, and where thirty-two children were born to him by two wives. Of these, three sons made a conspicuous figure in the republic of letters, being all professors of mathematics at the same time in three of the British universities, viz. David at Oxford, James at Edinburgh, and Charles at St Andrews.

Mr Gregory, the subject of this memoir, while he lived at Kinardie, was a jest among the neighbouring gentlemen for his ignorance of what was doing about his own farm, but an oracle in matters of learning and philosophy, and particularly in medicine, which he had studied for his amusement, and began to practise among his poor neighbours. He acquired such a reputation in that science, that he was employed by the nobility and gentlemen of that county, but took no fees. His hours of study were singular. Being much occupied through the day with those who applied to him as a physician, he went early to bed, rose about two or three in the morning, and, after applying to his studies for some hours, went to bed again and slept an hour or two before breakfast.

He was the first man in that country who had a barometer; and having paid great attention to the changes in it, and the corresponding changes in the weather, he was once in danger of being tried by the presbytery for witchcraft or conjuration. A deputation of that body waited upon him to enquire into the ground of certain reports that had come to their ears; but he satisfied them so far as to prevent the prosecution of a man known to be so extensively useful by his knowledge of medicine.

About the beginning of this century he removed with his family to Aberdeen, and in the time of Queen Anne's war employed his thoughts upon an improvement in artillery, in order to make the shot of great guns more destructive to the enemy, and executed a model of the engine he had conceived. Dr Reid informs us, that he conversed with a clock-maker in Aberdeen who had been employed in making this model; but having made many different pieces by direction without knowing their intention, or how they were to be put together, he could give no account of the whole. After making some experiments with this model, which satisfied him, the old gentleman was so sanguine in the hope of being useful to the allies in the war against France, that he set about preparing a field equipage with a view to make a campaign in Flanders, and in the mean time sent his model to his son the Savilian professor, that he might have his and Sir Isaac Newton's opinion of it. His son shewed it to Newton, without letting him know that his own father was the inventor. Sir Isaac was much displeased with it, saying, that if it had tended as much to the preservation of mankind as to their destruction, the inventor would have deserved a great reward; but as it was contrived solely for destruction, and would soon be known by the enemy, he rather deserved to be punished, and urged the professor very strongly to destroy it, and if possible to suppress the invention. It is probable the professor followed this advice. He died soon after, and the model was never found.

If this be a just account of the matter, and Dr Reid's veracity is unquestionable, we cannot help thinking that Newton's usual sagacity had, on that occasion, forsaken him. Were the implements of war much more destructive than they are, it by no means follows that more men would be killed in battle than at present. Muskets and cannons are surely more destructive weapons than javelines and bows and arrows; and yet, it is a well known fact, that since the invention of gunpowder, battles are not half so bloody as they were before that period. The opposite armies now seldom come to close quarters, a few rounds of musketry and artillery commonly decide the fate of the day; and had Mr Gregory's improvement been carried into effect, still fewer rounds would have decided it than at present, and the carnage would consequently have been less.

When the rebellion broke out in 1715, the old gentleman went a second time to Holland, and returned when it was over to Aberdeen, where he died about 1720, aged 93, leaving behind him a history of his own time and country, which was never published.

Gregory (Dr David). In addition to the account given in the *Encyclopædia* of this eminent mathematician, it may be proper to add, that he was a most intimate and confidential friend of Sir Isaac Newton, and was intrusted with a manuscript copy of the *Principia*, for the purpose of making observations on it. Of these Newton availed himself in the second edition, they having come too late for his first publication, which was exceedingly hurried by Dr Halley, from

from fears that Newton's backwardness would not let it appear at all. There is a complete copy of these observations preserved in the library of the university of Edinburgh, presented to it by Dr James Gregory, the present professor of the practice of medicine. These contain many sublime mathematical discussions, many valuable commentaries on the *Principia*, and many interesting anecdotes. There are in it some paragraphs in the hand writing of Huyghens relative to his Theory of Light. It would appear that this work of confidential friendship was the foundation of that system of physical and mathematical astronomy which has raised Dr Gregory to great eminence in the republic of letters.

GREGSTOWN, a village in Somerset county, New-Jersey, on the east side of Millstone river, 6 miles north-easterly of Princeton, and about 9 south-west of New-Brunswick.—*Morse.*

GRES, Cape au, a promontory on the eastern side of the Mississippi in the N. W. Territory, 8 leagues above the Illinois river, and the tract of country so called extends 5 leagues on that river. There is a a gradual descent back to delightful meadows, and to beautiful and fertile uplands, watered by several rivulets, which fall into the Illinois river, between 30 and 40 miles from its entrance into the Mississippi, and into the latter at Cape au Gres. The distance from the Mississippi to the Illinois across the country, is lessened or increased, according to the windings of the former river; the smallest distance is at Cape au Gres, and there it is between 4 and 5 miles. The lands in this intermediate space between the above two rivers are rich, almost beyond parallel, covered with large oaks, walnut, &c. and not a stone to be seen, except upon the sides of the river.

If settlements were begun here, the French inhabitants acknowledge that the Spanish settlements on the other side of the Mississippi would be abandoned; as the former would excite a constant succession of settlers, and intercept all the trade of the upper Mississippi.—*ib.*

GRINDING in Cutlery, a well known operation, by which edge-tools are sharpened. As commonly practised, the grinding of tools is attended with great inconveniency arising from the production or developement of heat by friction. The fact of sparks flying from a dry grindstone when a piece of iron or steel is applied to its surface during the rotation, has been seen by every one. The heat produced during this process is such that the steel very soon becomes ignited, and hard tools are very frequently softened and spoiled, for want of care during the grinding. When a cylindrical stone is partly immersed in a trough of water, the rotation must be moderate and the work slow, otherwise the water would soon be thrown off by the centrifugal force; and when this fluid is applied by a cock from above, the quantity is too small to preserve the requisite low temperature. It is even found, that the point of a hard tool, ground under a considerable mass of water, will be softened, if it be not held so as to meet the stream; sparks being frequently afforded even under the water

To find a remedy for this, Mr Nicholson was led, by some accounts which he received of German cutlery, to make the following experiment. He procured a Newcastle grindstone of a fine grit and ten inches in diameter, and also a block of mahogany to be used with emery on its face. Both the stone and the wooden block were mounted on an axis, to be occasionally applied between the centres of a strong lathe. In this situation both were turned truly cylindrical, and of the same diameter. The face of the wood was grooved obliquely in opposite directions, to afford a lodgement for the emery. The face of the stone was left smooth, and there was a trough of proper size applied beneath the stone to hold water. The grindstone was then used with water, and the wooden cylinder was faced with emery and oil. The instrument ground was a file, out of which it was proposed to grind all the teeth. The rotation was produced by the mechanism of the lathe; the velocity being such as to turn the grinding apparatus about five revolutions in a second. The stone operated but slowly, and the water from the trough was soon exhausted, with inconvenience to the workman, who could scarcely be defended from it but by slackening the velocity. The emery cylinder cut rather faster. But notwithstanding the friction was made to operate successively and by quick changes on the whole surface of the file, it soon became too much heated to be held with any convenience; and when a cloth was used to defend the hand, the work not only became awkward, but the heat increased to such a degree that the oil began to be decomposed, and emitted an empyreumatic smell. The stone was then suffered to dry, and the file tried upon its face. It almost immediately became blue, and soon afterwards red hot. Both the cylinders were then covered with tallow, by applying the end of a candle to each while revolving, and emery was sprinkled upon the cylinder of wood. The same tool was then applied to the grindstone in rapid motion. At the first instant the friction was scarcely perceptible; but very speedily afterwards the zone of tallow pressed by the tool became fused, and the stone cut very fast. The tool was scarcely at all heated for a long time; and when it began to feel warm, its temperature was immediately lowered by removing it to a new zone of the cylinder. The same effect took place when the experiment was repeated with the wooden cylinder.

It is not difficult to explain this by the modern doctrine of heat. When oil was used upon the wooden cylinder, the heat developed by the friction was employed in raising the temperature of the tool and of the fluid oil: but when tallow was substituted instead of the oil, the greatest part of the heat was employed in fusing this consistent body. From the increased capacity of the tallow, when melted, this heat was absorbed, and became latent, instead of being employed to raise the temperature: and whenever, by continuing the process, the tallow already melted began to grow hot, together with the tool, it was easy to reduce the temperature again by employing the heat on another zone of consistent tallow. He used these two cylinders, with much satisfaction, in a considerable quantity of work.

This promises to be a valuable discovery; and the public is obliged to the ingenious author of the Philosophical Journal for being at so much pains on this, as well as on other occasions, to render his science subservient to the useful arts.

Grose.

GROSE (Francis Esq; F.A.S.) was born, we believe, in 1731. He was the son of Mr Francis Grose of Richmond, jeweller, who filled up the coronation crown of George II. and died 1769. By his father he was left an independent fortune, which he was not of a disposition to add to, or even to preserve. He early entered into the Surrey militia, of which he became adjutant and paymaster; but so much had dissipation taken possession of him, that in a situation which above all others required attention, he was so careless as to have for some time (as he used pleasantly to tell) only two books of accounts, viz. his right and left hand pockets. In the one he received, and from the other paid; and this too with a want of circumspection which may be readily supposed from such a mode of book-keeping. His losses on this occasion roused his latent talents. With a good classical education he united a fine taste for drawing; and encouraged by his friends, as well as prompted by his situation, he undertook the work from which he derived both profit and reputation; we mean, his Views of Antiquities in England and Wales, which he first began to publish in numbers in the year 1773, and finished in the year 1776. The next year he added two more volumes to his English Views, in which he included the islands of Guernsey and Jersey, which were completed in 1787. This work answered his most sanguine expectations; and, from the time he began it to the end of his life, he continued without intermission to publish various works (a list of which we subjoin), generally to the advantage of his literary reputation, and almost always to the benefit of his finances. His wit and good humour were the abundant source of satisfaction to himself, and entertainment to his friends. He visited almost every part of the kingdom, and was well received wherever he went. In the summer of 1789 he set out on a tour in Scotland; the result of which he began to communicate to the public in 1790 in numbers. Before he had concluded this work, he proceeded to Ireland, intending to furnish that kingdom with views and descriptions of her antiquities, in the same manner he had executed those of Great Britain; but soon after his arrival in Dublin, being at the house of Mr Home there, he suddenly was seized at table with an apoplectic fit, on the 6th of May, 1791, and died immediately. He was interred in Dublin.

"His literary history (says a friend), respectable as it is, was exceeded by his good humour, conviviality, and friendship. Living much abroad, and in the best company at home, he had the easiest habits of adapting himself to all tempers; and, being a man of general knowledge, perpetually drew out some conversation that was either useful to himself, or agreeable to the party. He could observe upon most things with precision and judgment; but his natural tendency was to humour, in which he excelled both by the selection of anecdotes, and his manner of telling them: it may be said, too, that his figure rather assisted him, which was in fact the very title page to a joke. He had neither the pride nor malignity of authorship; he felt the independency of his own talents, and was satisfied with them without degrading others. His friendships were of the same cast; constant and sincere, overlooking some faults, and seeking out greater virtues. He had a good heart; and, abating those little indiscretions natural to most men, could do no wrong."

Grose | Groton.

He married at Canterbury, and resided there some years, much beloved and respected for his wit and vivacity: "which (another friend observes), though he possessed in an extreme degree, was but little tinctured with the caustic spirit so prevalent among spirits of that class. His humour was of that nature which exhilarates and enlivens, without leaving behind it a sting; and though perhaps none possessed more than himself the faculty of "setting the table in a roar," it was never at the expence of virtue or good manners. Of him, indeed, may be said in the words of Shakespeare,

————— a merrier man,
Within the limits of becoming mirth,
I never spent an hour's talk withal:
His eye begets occasion for his wit;
And every object that the one doth catch,
The other turns to a mirth-moving jest.

"Of the most careless, open, and artless disposition, he was often (particularly in the early part of his life) the prey of the designing; and has more than once (it is believed) embarrassed himself by too implicit confidence in the probity of others. A tale of distress never failed to draw commiseration from his heart; and often has the tear been discovered gliding down that cheek which a moment before was flushed with jocularity."

He was father of Daniel Grose, Esq; captain of the royal regiment of artillery (who, after several campaigns in America, was appointed in 1790 deputy governor of the new settlement at Botany Bay), and some other children.

His works are as follow:

1. The Antiquities of England and Wales, 8 vols. 4to and 8vo. 2. The Antiquities of Scotland, 2 vols. 4to and 8vo. 3. The Antiquities of Ireland, 2 vols. 4to and 8vo. 4. A Treatise on ancient Armour and Weapons, 4to, 1785. 5. A Classical Dictionary of the Vulgar Tongue, 8vo, 1785. 6. Military Antiquities; being a History of the English Army from the Conquest to the present time, 2 vols 4to, 1786, 1788. 7. The History of Dover Castle, by the Rev. William Darell, 4to, 1786. 8. A Provincial Glossary, with a Collection of local Proverbs and popular Superstitions, 8vo, 1788. 9. Rules for drawing Caricatures, 8vo, 1788. 10. Supplement to the Treatise on Ancient Armour and Weapons, 4to, 1789. 11. A Guide to Health, Beauty, Honour, and Riches; being a collection of humourous Advertisements, pointing out the means to obtain those blessings; with a suitable introductory Preface, 8vo. 12. The Olio; being a Collection of Essays in 8vo, 1793.

GROS MORNE stands in the middle of the north peninsula of the island of St Domingo, between the mountain and the head waters of a river which falls into the sea 4 leagues to the north, and a league and a half west of Port de Paix. It is equally distant, 11 leagues north-east of Point Paradis, and north-west of Les Gonaives. N. lat. 19° 46', W. long. from Paris 75° 13'.—*Morse.*

GROTON, a township in Caledonia county, in Vermont, is situated westward of and adjoining to Ryegate

Evenate township on Connecticut river, and 9 miles north-westerly of Stephen's Fort on that river. It contains 45 inhabitants.—*ib.*

GROTON, a township in Middlesex county, Massachusetts, 35 miles N. W. of Boston, and contains 1,840 inhabitants.—*ib.*

GROTON, a township in New London county, Connecticut, having Fisher's Island Sound on the southward, and Thames river on the west; which separates it from New-London, to which it formerly belonged. It was incorporated in 1705, and consists of two parishes, containing 3,946 inhabitants. In 1770 there were 140 Indians here; 44 of whom could read, and 17 were church members. On a height, on the bank of the Thames, opposite New-London city, stood Fort Griswold, memorable for being stormed on the 6th of September, 1781, by Benedict Arnold, a native of Connecticut, after he had become a traitor to his country. Here 70 men, the flower of the town, were put to the sword, after they had surrendered themselves prisoners. The compact part of the town was burnt at the same time, and sustained losses to the amount of £23,217. Fort Griswold defends the harbour of New-London.—*ib.*

GROVE *Point* forms the north side of the mouth of Sassafras river, in Chesapeak Bay, 5 miles south-south-west of Turkey Point.—*ib.*

GROVET's *Creek*, in the State of Tennessee, lies 7 miles from King's Spring, and 2 from the foot of Cumberland Mountain.—*ib.*

GRYALVA, a river in the province of Chiapa, in New Spain, which is said to breed certain amphibious beasts not to be found in any other place. They resemble monkeys, and are spotted like tygers; they hide themselves generally under water, and if they see any man or beast swim by, they twist their tails about a leg or arm to draw them to the bottom; and yet it has never been observed that they eat them.—*ib.*

GRYSON, a new county of Virginia, taken from Montgomery, which bounds it on the north. It has the State of N. Carolina, south, Henry and Wythe counties on the east and west.—*ib.*

GUACANA, a village in New Spain, near the mountain Jeruyo, which was destroyed by a volcano in that mountain, in 1760.—*ib.*

GUADALAJARRA, or *Guadalaxara*, a province in the audience of Galicia, in Old Mexico or New Spain, and its capital, an episcopal city of the same name, both large and beautiful. The city was built anno 1531, by one of the family of the Guzmans; and the bishopric, which was before settled at Compostella, was translated thither in 1570. It is situated on a delightful and fertile plain, watered with several streams and fountains, not far from Baranja river. The air of the country is temperate, and the soil so fertile, that it yields 100 to one; and all the fruits of Europe grow in luxuriance and abundance. N. lat. 20° 50′, W. long. 104° 49′. The province is watered by the Guadalaxara river.—*ib.*

GUADALAXARA, or *Great River*, in Mexico or New Spain, rises in the mountains of the valley of Toloccan, where stands the city of Guadalajarra, or Guadalaxara, the capital of New Galicia. After running a course of more than 600 miles, it empties into the Pacific Ocean, in the 22d degree of N. lat. It has stupendous falls, 15 miles south of the city of its name.—*ib.*

GUAIRA, a Spanish province in the east division of Paraguay, in S. America. Its city is Cividad Real, called also Guaira, and Oliveros.—*ib.*

GUAMALIES, a province in the jurisdiction of the archbishop of Lima, in S. America, and empire of Peru, begins 80 leagues north-east of Lima, and extends along the centre of the Cordillera. The Indian inhabitants apply themselves to weaving, and making a great variety of baizes, serges, and other stuffs, with which they carry on considerable trade with the other provinces.—*ib.*

GUAMAN VILLAS, a jurisdiction under the archbishop of Lima, 7 leagues from Guamanga. It is highly fertile, abounding with corn, fruits, pastures, cattle in great quantities, and all manner of esculent vegetables. The Indians here are equally industrious as those above mentioned, making baizes, corded stuffs, &c. which they send to Cusco and other provinces.—*ib.*

GUAMANGA, or *Guamanca*, or *St Juan de la Vittoria*, a city of Peru, about 60 leagues south-east of Lima, and having Pisco between it and the sea. It was founded by Pizarro, in 1539. The houses are all of stone, covered with slates. There are in it 3 elegant churches, several convents, and a rich hospital; being the seat of a bishop, under the archbishop of Lima, the seat of a governor, and the capital of a small province. The air is wholesome and temperate. The soil produces wheat, and the meadows breed numerous herds of cattle There are in the province mines of gold, silver, iron, lead, copper, and sulphur. The famous quick-silver mines of Guancavelica are 9 or 10 leagues from this city. S. lat. 12° 20′, W. long. 72° 36′.—*ib.*

GUANA PATINA, a volcano near Arequipa, in the valley of Quilca, in S. America, and empire of Peru; whose eruption, assisted by an earthquake, laid Arequipa in ruins in 1600.—*ib.*

GUANCHA BELICA, a jurisdiction subject to the archbishop of Lima, in Peru, 30 leagues north of the city of Guamanga; has very rich quick-silver mines, but otherwise very barren.—*ib.*

GUANCHACO, a port or harbour in Peru, S. America, about 2 leagues north of Truxillo, and the channel of its maritime commerce, situated in 8° 6′ S. lat. in the South Sea.—*ib.*

GUANTA, a jurisdiction north-north-west of Guamanga 4 leagues, in the empire of Peru; under the archbishop of Lima. Its rich silver mines are nearly exhausted.—*ib.*

GUANZAVELICA, or *Guancavelica*, a town of Peru in South-America, and in the audience of Lima. It is rich and abounds in mines of quick-silver; 120 miles north-east of Pisco, and 175 south-east of Lima. S. lat. 13°, W. long. 88° 30′. The famous quick-silver mines called *Guanzavelica*, or *El Assiento de Oropeso*, not far from the above town, near the city of Oropeso, were discovered by the Spaniards in 1566, and produce annually a million pounds of quick-silver, which is transported by land to Lima, afterwards to Arica, and thence to Potosi, where they make use of it to melt and refine the silver; and it yields to the Spanish treasury 40,000 ducats a year, besides other emolu-

emoluments. The quick-ſilver is found in a whitiſh maſs reſembling brick half burned. This ſubſtance is volatilized by fire, and received in ſteam by a combination of glaſs veſſels, where it condenſes by means of a little water at the bottom of each veſſel, and forms a pure heavy liquid.—*ib.*

GUARA, a town in its own juriſdiction on the road from Truxillo to Lima, containing about 200 houſes. It has a pariſh church, and a convent of Franciſcans, ſurrounded by fine plantations, and delightful improvements. At the ſouth end of Guara ſtands a large tower with a gate, and over it a kind of redoubt. This tower is erected before a ſtone bridge, under which runs Guara river. It lies in S. lat. 11° 31′ 36″. Not far from this town are ſtill to be ſeen a great many ruinous remains of the edifices of the Yncas or Incas; ſuch as walls of palaces, large dykes, by the ſides of ſpacious highways, fortreſſes, and caſtles, erected for checking the inroads of the enemy. —*ib.*

GUARCHI, a juriſdiction 6 leagues eaſt of Lima, in Peru, extends itſelf above 40 leagues along the Cordilleras, abounding in grain and fruits. It has ſome ſilver mines, but as the metal is indifferent, few are wrought.—*ib.*

GUARMOY, a ſmall maritime town of Peru, in South-America. It is the reſidence of a corregidore; has a good harbour, and lies 134 miles north-weſt of Lima, S. lat. 18° 3′ 53″.—*ib.*

GUASTACA, or *Panuco*, a province which borders on New Leon and Mexico, in which province are grain, cochineal, and ſome very rich ſilver mines. All the ſhores are low, overflowed, unhealthy, and full of ſalt marſhes.—*ib.*

GUATIMALA, (*Encycl.*). There is a great chain of high mountains, which runs acroſs it from eaſt to weſt, and it is ſubject to earthquakes and ſtorms. It is, however, very fertile, and produces great quantities of chocolate, cochineal, cotton, indigo, honey, ſome balſam and wood. The merchandize of the province is generally conveyed to the port of St Thomas in the bay of Honduras, to be ſent to Europe. The way acroſs this province to the South Sea is about 65 leagues, and is the next to that from Vera Cruz to Acapulco. This province is called by the Indians *Quatuemallac*, which ſignifies a *rotten tree*.

St Jago de Guatimala, the capital city, is ſituated in a valley, through the midſt of which runs a river between two burning mountains. In 1541 this city was ruined by a dreadful tempeſt, and a number of the inhabitants were buried in the ruins. It was rebuilt at a good diſtance from the volcano, and became a large and rich town, with a biſhop's ſee, and an univerſity; but it was ſwallowed up by an earthquake in 1773. It contained about 60,000 inhabitants of all colours, and was immenſely rich, but there are no traces of it left. The loſs was valued at 15 millions ſterling; and it was the third city in rank in Spaniſh America. In this dreadful earthquake 8,000 families inſtantly periſhed. New Guatimala is built at ſome diſtance, is well inhabited, and carries on a great trade. N. lat. 13° 40′, W. long. 90° 30′.—*ib.*

GUAXACA, a province in the audience of Mexico, in New Spain, N. America, and its capital city of the ſame name. It reaches from the bay of Mexico on the north to the South Sea, having the province of Tlaſcala on the north-weſt, and thoſe of Chiapa and Tabaſco on the ſouth-eaſt. It extends nearly 95 leagues along the South Sea, 50 along the bay of Mexico, and near 120, ſay ſome, along the confines of Tlaſcala, but not above 50 on thoſe of Chiapa. The air here is good, and the ſoil fruitful, eſpecially in mulberry trees; ſo that it produces more ſilk than any province in America. Except the valley of Guaxaca (which is famous for giving the title of Marques del Valle to Ferdinand Cortez, the conqueror of Mexico) the greateſt part is mountainous, yet abounding with wheat, cattle, ſugar, cotton, honey, cocoa, plantanes and other fruits. It has rich mines of gold, ſilver, and lead; and all its rivers have gold in their ſands. Caſſia, cochineal, cryſtal, and copperas abound alſo here. Vanilla, a drug, uſed as a perfume to give chocolate a flavor, grows plentifully in this province. There were in this province 120 monaſteries, beſides hoſpitals, ſchools, and other places of public charity, 150 conſiderable towns, beſides upwards of 300 villages. But now the province is ſaid to be thinly inhabited.—*ib.*

GUAXACA, the capital of the laſt mentioned province, is a biſhop's ſee, and the reſidence of a governor. It lies 230 miles ſouth of the city of Mexico, 120 weſt of Spirito Santo, and 132 ſouth of the gulf of Mexico, and of Vera Cruz, in the delightful valley of Guaxaca, which is 40 miles in length and 20 in breadth; and on the road leading through Chiapa to Guatimala. This city contains a very ſtately cathedral, and ſeveral thouſand families, both Spaniards and Indians. It carries on a conſiderable trade with the N. and S. ſeas. The river is not fortified, ſo that it lies open to invaſion. The Creolian clergy here are bitter enemies to the Spaniſh clergy. According to ſome, the proper name of Guaxaca is *Antiquera*; but this laſt, others make a ſeparate town and biſhop's ſee alſo, ſituated about 80 miles to the S. W. It is ſaid to have a ſtately cathedral, adorned with many large and high pillars of marble, each of which is one entire ſtone. It is ſituated in N. lat. 18° 2′, W. long. 101° 10′. Guaxaca is ſituated, according to ſome, in N. lat. 17° 45′. W. long. 100°.—*ib.*

GUAYALAS, a province and juriſdiction in the archbiſhopric of Lima, in Peru, S. America; extends along the centre of the Cordilleras, begins 50 leagues N. N. E. of Lima; produces grain, fruits, and paſture for cattle.—*ib.*

GUAYAQUIL, called by ſome *Guiaquil*, by others *Guagaquil* and *Guayakal*, a city, bay, harbour and river, in Peru, South-America. Guayaquil city is the ſecond of Spaniſh origin, being as ancient as 1534; is ſituated on the weſt ſide of the river Guayaquil, north of the iſland of Puna, at the head of the bay, and about 155 miles S. S. W. of Quito, in 2° 11′ ſouth lat. 79° 17′ weſt long. Cividad Viega, or Old Town, was its firſt ſituation, but it was removed about a quarter of a league in 1693 by Orellana; and the communication over the great ravins or hollows of water, preſerved between the old and new towns by a wooden bridge of half a quarter of a league. The city is about two miles in extent; is defended by three forts, two on the river near the city, and the third behind it, guarding the entrance of a ravin. The churches, convents, and houſes are of wood. It contains about 20,000 inhabitants—Europeans, creoles and other casts; besides a number of strangers drawn hither by commercial interests. The women here are famed for their personal charms, polite manners, and elegant dress. The salt creek here abounds with lobsters and oysters; but the fish in the neighbourhood are not esteemed, being full of bones, and unpalatable. But this place is most noted for a shell-fish called *turbine*, no bigger than a nut, which produces a purple reckoned to exceed all others in the world, and to vie with that of the Tyrians. It is called the purple of Punta, a place in the jurisdiction of Guayaquil. With this valuable and scarce purple, they dye the threads of cotton, ribbands, laces, &c. and the weight and colour are said to exceed according to the hours of the day; so that one of the first preliminaries to a contract is to settle the time when it shall be weighed. The dye is only the blood of the fish, pressed out by a particular process; and the cotton so dyed is called by way of eminence *caracollillo*. The river Guayaquil is the channel of its commerce; and the distance of the navigable part of it, to the custom-house of Babahoio is reckoned about 24 leagues. The commerce of this place is considerable; the productions of the country alone form the most considerable part of it; these are cocoa, timber, salt, horned cattle, mules, and colts; Guinea pepper, drugs, and lana de ceibo, a kind of wool, the product of a very high and tufted tree of that name, being finer than cotton. It is used for matrasses and beds.—*ib.*

GUAYARA, La, a maritime town, and one of the chief of Caraccas, in South-America.—*ib.*

GUERITE, in Fortification, a centry-box; being a small tower of wood, or stone, usually placed on the point of the bastion, or on the angles of the shoulder, to hold a centinel, who is to take care of the ditch, and watch against a surprise.

GUIANDOT, a river of Virginia, which rises in the Cumberland Mountain, and running a N. by W. course about 80 miles, falls into the Ohio river, about 34 miles below the Great Kanhaway. It is said to be 60 yards wide at its mouth, and as many miles navigable for canoes.—*Morse.*

GUILDHALL, a township in Essex county in Vermont, is situated on Connecticut river, and contains 158 inhabitants. It is opposite the mouth of Israel river in New-Hampshire.—*ib.*

GUILFORD, a township in Franklin county, Pennsylvania.—*ib.*

Guilford, a township in Windham county, Vermont, on the west bank of Connecticut river, and opposite to the mouth of Ashuelot river in New-Hampshire. It has Hinsdale on the south-east, and the State of Massachusetts on the south, and contains 2432 inhabitants.—*ib.*

Guilford, a post-town of Connecticut, in New-Haven county, situated on the south side of Long-Island Sound, about 18 miles E. by S. of New-Haven city. The township is large, and is divided into 5 parishes, and was settled in 1639. It was called *Menuncatuck* by the Indians.—*ib.*

Guilford *County*, in Salisbury district, North-Carolina, is bounded east by Orange, west by Rowan, south by Rockingham county, and north by the state of Virginia. It is noted for the extensive and rich tracts called New Garden, Buffaloe and Deep river lands. It contains 7191 inhabitants, inclusive of 576 slaves. Chief town, Martinville.—*ib.*

Guilford *Court-House*. It is on the post-road from Halifax to Salisbury, 48 miles south-west of Hillsborough, and 61 eastward of Salisbury.—*ib.*

GUILLOTINE, a new term introduced into the languages of Europe by the mournful effects of fanaticism in the holy cause of liberty. Our readers are not ignorant that this is the name given by the National Assembly of France to the engine of decapitation, which those usurpers of the legislative authority decreed to be the sole punishment of those condemned to death for their crimes. This decree was issued on March 20th 1792.

We do not imagine that the world will derive much useful instruction from a minute description of this terrible instrument of public justice; and therefore content ourselves with giving two figures of it, sufficiently expressive of its construction. It is only the revival of an instrument used in former times. The earliest accounts that we have of it is, that it was used in the barony of Halyfax in Yorkshire. It was also set up in Scotland; but we have no certain information that it has ever been used; and it is still shewn as a sort of curiosity by the name of the *Mayden*. See Maiden, *Encycl.*

Eratosthenes could not think of a better way of handing down his name to future ages than by burning the temple of Diana at Ephesus; Dr Guillotin, physician at Lyons, and member of the self-named National Assembly of France, thought himself honoured by the decree which associated his name with this instrument of popular vengeance. It was indeed proposed by him as an instrument of mercy, in a studied harangue, filled with that sentimental slang of philanthropy, which costs so little, promises so much, and has now corrupted all the languages of Europe. His invention is indeed one of the most expressive specimens of Gallic philanthropy, whose tender mercies are cruel; and was accordingly received with loud applauses, both from the house, and from the galleries. To proceed, however, with imposing dignity, it was referred to the consideration of a committee, with injunctions to ask the opinion of able surgeons of its efficiency. Mr Louis, a celebrated surgeon of Paris, declared it well fitted for the task, in a long pedantic dissertation; in which he takes occasion to deliver, with academic coldness, a theory of the operation of cutting instruments; and says that he had examined the edge of the guillotine and other such instruments, with a microscope, and had discovered that the finest edges were toothed like a saw. M. Guillotin, he said, had therefore with great judgment made the axe of his engine of death with a sloping edge, by which means *il glissoit d'une façon infinitment plus douce.* This dissertation was so much to the taste of the humane legislature, that they rewarded Mr Louis with 2000 livres, and published it in the Paris Journals. As to the inventor, he reaped all the benefit from it which he so kindly intended for the nation, by the trial of it on his own person, when he fell under the displeasure of Robespierre.

We acknowledge, that in as far as this instrument lessens the duration of the horrid conflict with the king of of terrors, and probably diminishes the corporeal sufferance, it may be called merciful (alas! the day!); but we question much, whether the dreadful agitation of soul is not rather increased by the long train of preparatory operations. The hands of the convict are tied behind his back: he is then stretched along on his face on a strong plank, and his precise position adjusted to the instrument. When fastened to the plank, it is pushed forward into its place, under the fatal edge, his neck adjusted to the block, and a basket placed just before his eyes (for the face of Louis XVI. was not covered) to receive his head. This must employ a good deal of time, and every moment is terrible.

The construction has received many alterations and refinements; and has at last been made so compendious and portable, as to become part of the travelling equipage of a commissioner from the National Assembly, sent on a provincial or special visitation. Thus did the sovereign people become terrible in majesty. So sensible was the Assembly of the advantages of this awful impression, or so intoxicated with the enjoyment of irresistible power, that they have thought their coins ornamented by this attribute of their supremacy: and as Jupiter is distinguished by his thunderbolt, so the majesty of the people is distinguished by the no less fatal axe. We have seen a piece of ten sous, struck at Mentz in 1793, and issued as current money, at the very time that they were planting the tree of liberty in that illuminated city by the hands of Custine and his troops. The device is the fasces and axe of ancient Rome, crowned with the red cap, and surrounded by a laurel wreath. The inscription is, *Republique Françoise*, 1793, *an.* 2d. Fully impressed with the same sentiments, Lequinio, the sentimental novellist of France, whom Mercier compares with the tender, the heart-touching Sterne—Lequinio, now commissioner sent by the National Assembly to regenerate Normandy and Brittany, writes to his masters, that "he is very successful in conversions from superstition to sound reason." He opposes to the bible and the relicts of the saints the constitution and the guillotine. "And you would wonder (says he) at my success—The wise (but they are few) give up their prejudices at once; but the multitude, the stupid worshippers of *Notre Dame*, look at our lady the guillotine; are silent, become serious, and their doubts vanish;—they are converted. This is your *labarum*—*in hoc signo vinces*."

GULA, Gueule, or Gola, in Architecture, a wavy member whose contour resembles the letter S, commonly called an Ogee.

GULF of Florida, or *New Bahama Channel*, is bounded on the west by the peninsula of East-Florida, and on the east by the Bahama Islands. It is generally about 40 miles wide, and extends from the 25th to the 28th degree of N. latitude.—*Morse.*

Gulf Stream. This remarkable phenomenon is a current in the ocean which runs along the coast, at unequal distances from Cape Florida to the Isle of Sables and the banks of Newfoundland, where it turns off and runs down through the Western islands; thence to the coast of Africa, and along that coast in a southern direction, till it arrives at, and supplies the place of those waters carried by the constant trade-winds from the coast of Africa toward the west, thus producing a constant circulating current. This stream is about 75 miles from the shores of the Southern states, and the distance increases as you proceed northward. The width of it is about 40 or 50 miles, widening towards the north. Its common rapidity is three miles an hour. A north-east wind narrows the stream, renders it more rapid, and drives it nearer the coast. North-west and west winds have a contrary effect. The Gulf-Stream is supposed to be occasioned by the trade-winds that are constantly driving the water to the westward, which being compressed in the Gulf of Mexico, finds a passage between Florida and the Bahama Islands, and runs to the north-east along the American coast. This hypothesis is confirmed by another fact: It is said that the water in the Gulf of Mexico is many yards higher than on the western side of the continent in the Pacific Ocean. It is highly probable that the sand carried down by great rivers into bays, and the current out of these bays meeting with the Gulf Stream, by their eddies, have formed Nantucket Shoals, Cape Cod, George's Bank, the Island of Sable, &c.

Skilful navigators, who have acquired a knowledge of the extent to which this stream reaches on the New-England coast, have learnt, in their voyages from Europe to New-England, New-York, or Pennsylvania, to pass the banks of Newfoundland in about 44° or 45° N. lat. to sail thence in a course between the northern edge of the Gulf Stream, and the shoals and banks of Sable Island, George's Bank, and Nantucket, by which they make better and quicker voyages to America. —*ib.*

GUNPOWDER, as we have observed in the *Encyclopædia* under the word Gun, has been known in the east, and particularly in China, from a period of very remote antiquity. No man, however, seems to have suspected that the knowledge of it was conveyed from the east into Europe; but all have agreed to allow the merits of the invention both to friar Bacon and to Bartholomew Schwartz. This generally received opinion has been lately controverted by citizen Langles, who, in a memoir read in the French national institute, contends, that the knowledge of gunpowder was conveyed to us from the Arabs, on the return of the Crusaders to Europe. He assures us that the Arabs made use of it in 690 at the siege of Mecca; and he adds, that they derived it from the Indians, among whom it must have been known in the remotest ages, since their sacred books (the Vedam) forbid the use of it in war.

It is indeed extremely probable, that the composition of gunpowder was known in India at a very early period; for in whatever country nature forms nitre in the greatest plenty, there its deflagrating quality is most likely to be first observed; and a few experiments founded on that observation, will lead to the composition which produces such sudden and violent effects. "Nitre (says Sir George Staunton) is the natural and daily produce of China and India; and there, accordingly, the knowledge of gunpowder seems to be coeval with that of the most distant historic events. Among the Chinese, it has been applied at all times to useful purposes, such as blasting rocks, and removing great obstructions, and to those of amusement in making a vast variety of fire works. It was also used as a defence, by undermining the probable passage of the enemy, and blowing him up. But its force had not been directed through strong metallic tubes as it was by Europeans soon after they had discovered it. And though, in imitation of Europe, it has been introduced into the armies of the East, other modes of warfare are sometimes still preferred to it."

Of gunpowder manufactured by those who have manufactured it so long, it is desirable to know the composition and the qualities. It was therefore natural for the Hon. George Napier, when superintending the royal laboratory at Woolwich, and making experiments upon so necessary an implement of modern war, to procure some Chinese powder from Canton.

This he did; and analyzing two ounces of it, he found, after repeating the operation six times, that the mean result gave the following proportions*. Nitre 1 oz. 10 dwts. charcoal 6 dwts. sulphur 3 dwts. 14 grs. Here is a deficiency in weight of ten grains, which M. Napier supposes the consequence of some defect in his process; but as M. Baumé, a French chemist, made a variety of experiments to obtain a total separation of the sulphur from the charcoal of gunpowder, and was never able to effect it, one fourteenth part remaining united, three grains must be deducted from the charcoal, and added to the sulphur to give the accurate proportion of the ingredients; which by turning to the article Gunpowder, *Encycl.* the reader will perceive differs somewhat from the proportion of the same ingredients in the gunpowder of Europe. This Chinese powder was usually large grained and not strong, but very durable. It had been made many years when our author got it; yet there was no visible symptom of decay, the grain being hard, well coloured, and though angular, it was even-sized, and in perfect preservation.

* *Transactions of the Royal Irish Academy.*

When we consider the operations in which gunpowder is employed, it is obvious that it must be an object of importance to ascertain its explosive force; and yet there is scarcely a subject concerning which the most approved writers have so much differed. Mr Robins, who has done more towards perfecting the art of gunnery than any other individual, states the explosive force of gunpowder to be 1000 times greater than the mean pressure of the atmosphere; while the celebrated Daniel Bernouilli determines it not to be less than 10,000 times this pressure. Such a difference of opinion led Count Rumford to pursue a course of experiments, of which some were published in the Transactions of the Royal Society for the year 1781, and the remainder in the Transactions of the same Society for 1797; with the view principally of determining the initial expansive force of gunpowder. By one of these experiments, it appeared that, calculating even on Mr Robins's own principles, the force of gunpowder, instead of being 1000 times, must at least be 1308 times greater than the mean pressure of the atmosphere. From this experiment, the Count thought himself warranted in concluding, that the principles assumed by Mr Robins were erroneous, and that his mode of ascertaining the force of gunpowder could never satisfactorily determine it. Despairing of success in that way, he resolved to make an attempt for ascertaining this force by actual measurement; and after many unsuccessful experiments, he was at length led to conclude, that this force was at least 50,000 times greater than the mean pressure of the atmosphere.

Mr Robins apprehends that the force of fired gunpowder consists in the action of a permanently elastic fluid, similar, in many respects, to common atmospherical air; and this opinion has been very generally received: but Count Rumford thinks, that though the permanently elastic fluids, generated in the combustion of gunpowder, assist in producing the effects which result from its explosion, its enormous force, allowing it to be 50,000 times greater than the mean pressure of the atmosphere, cannot be explained, without supposing that it arises principally from the elasticity of the aqueous vapour generated from the powder in its combustion.

"The brilliant discoveries of modern chemists (says he) have taught us, that both the constituent parts of which water is composed, and even water itself, exist in the materials which are combined to make gunpowder; and there is much reason to believe that water is actually formed, as well as disengaged, in its combustion. M. Lavoisier, I know, imagined that the force of fired gunpowder depends in a great measure upon the expansive force of uncombined *caloric*, supposed to be let loose in great abundance during the combustion or deflagration of the powder: but it is not only dangerous to admit the action of an agent whose existence is not yet clearly demonstrated; but it appears to me that this supposition is quite unnecessary, the elastic force of the heated aqueous vapour, whose existence can hardly be doubted, being quite sufficient to account for all the phænomena. It is well known that the elasticity of aqueous vapour is incomparably more augmented by any given augmentation of temperature than that of any permanently elastic fluid whatever; and those who are acquainted with the amazing force of steam, when heated only to a few degrees above the boiling point, can easily perceive that its elasticity must be almost infinite when greatly condensed and heated to the temperature of red hot iron; and this heat it must certainly acquire in the explosion of gunpowder. But if the force of fired gunpowder arises *principally* from the elastic force of heated aqueous vapour, a cannon is nothing more than a *steam engine* upon a peculiar construction; and upon determining the ratio of the elasticity of this vapour to its density, and to its temperature, a law will be found to obtain very different from that assumed by Mr Robins in his Treatise on Gunnery."

In order to measure the elastic force of fired gunpowder, Count Rumford adopted a new plan; and, instead of causing the generated elastic fluid to act on a moveable body through a determined space, which he had found to be ineffectual to his purpose, he contrived an apparatus in which this fluid should be made to act, "by a determined surface against a weight, which, by being increased at pleasure, should at last be such as would just be able to confine it, and which in that case would just counterbalance and consequently *measure* the elastic force."

Having succeeded in setting fire to the powder, without any communication to the external air, "by causing the heat employed for that purpose to pass through the solid substance of the barrel, it only remained to apply such a weight to an opening made in the barrel, as the whole force of the generated elastic fluid should not be able to lift or displace." Many precautions were necessary. A solid block of very hard stone,

ſtone, four feet four inches ſquare, was placed upon a bed of ſolid maſonry, which deſcended ſix feet below the ſurface of the earth. Upon this block of ſtone, which ſerved as a baſe to the whole machinery, was placed the ſmall barrel, in which the exploſions were made, with its opening directly upwards. This opening was cloſed by a ſolid hemiſphere of hardened ſteel, on which the weight to be overcome by the exploſion was laid. Having charged the barrel with 10 grains of powder, its whole contents being about 28 grains, and a 24 pounder weighing 8081 lbs avoirdupois, being placed on its caſcabel ſo as by its weight to confine the generated elaſtic fluid, a heated iron ball was applied to the end of the vent tube, (a ſmall ſolid projection from the centre of the bottom of the barrel). In a few moments the powder took fire, though the exploſion made a very feeble report; and when the weight was raiſed, the confined elaſtic vapour ruſhed out of the barrel. The ſlight effect produced by this exploſion induced ſome of the attendants on this occaſion to undervalue the importance of this experiment, and to form a very inadequate idea of the real force of the elaſtic fluid that had been thus almoſt inſenſibly diſcharged. In a ſecond experiment, the barrel was filled with powder, and the ſame weight laid on as before. The barrel was made of the beſt hammered iron, and uncommonly ſtrong. The charge of powder amounted to little more than $\frac{1}{10}$ of a cubic inch, which is not ſo much as would be required to load a ſmall pocket piſtol, and not *one-tenth* part of the quantity frequently uſed for the charge of a common muſket. Yet this inconſiderable quantity of powder, when ſet on fire, exploded with a force that burſt the barrel, and with a loud report that alarmed the whole neighbourhood.

The author proceeds to make an eſtimate from the known ſtrength of iron, and the area of the fracture of the barrel in the preceding experiment, of the real force employed by the elaſtic vapour to burſt it; and he computes that it muſt have been equal to the preſſure of a weight of 412529 lbs.; which, by another computation, he found to be 55004 times greater than the mean preſſure of the atmoſphere. By another proceſs, he inveſtigates the ſtrength of the iron of which the barrel was made; and he thence finds that the force required to burſt it was equal to the preſſure of a weight of 410624½ lbs. This weight, reduced into atmoſpheres, gives 54750 atmoſpheres for the meaſure of the force exerted by the elaſtic fluid in the preſent inſtance. This force muſt be conſiderably leſs than the initial force of the elaſtic fluid generated in the combuſtion of gunpowder, before it has begun to expand; "for it is more than probable (ſays Count Rumford) that the barrel was in fact burſt before the generated elaſtic fluid had exerted all its force, or that this fluid would have been able to have burſt a barrel ſtill ſtronger than that uſed in the experiment."

After having ſhewn the extreme force of fired gunpowder, the Count adverts to an objection which may be made againſt his deductions. How does it happen that fire-arms and artillery of all kinds, which certainly are not calculated to withſtand ſo enormous a force, are not always burſt when they are uſed? Inſtead of anſwering this queſtion, by aſking how it happened that the extremely ſtrong barrel uſed in his experiment could be burſt by the force of gunpowder, if this force be not in fact much greater than it has ever been ſuppoſed to be, he proceeds to ſhew that the combuſtion of gunpowder, inſtead of being inſtantaneous, as Mr Robins's theory ſuppoſes, is much leſs rapid than has hitherto been apprehended; an obſervation which, if eſtabliſhed, is certainly ſufficient to anſwer the objection.

He remarks, that it is a well-known fact, that on the diſcharge of fire-arms of all kinds, there is always a conſiderable quantity of unconſumed grains of gunpowder blown out of them; and what is very remarkable, as it leads directly to a diſcovery of the cauſe of this effect, theſe unconſumed grains are not merely blown out of the muzzles of fire-arms, but come out alſo by their vents or touch-holes, where the fire enters to inflame the charge, as many perſons who have had the misfortune to ſtand with their faces near the touch-hole of a muſket, when it has been diſcharged, have found to their coſt.

It appears extremely improbable to our author, if not abſolutely impoſſible, that a grain of gunpowder actually in the chamber of the piece, and completely ſurrounded by flame, ſhould, by the action of that very flame, be blown out of it without being at the ſame time ſet on fire. And, if this be true, he conſiders it as a moſt deciſive proof, not only that the combuſtion of gunpowder is leſs rapid than it has generally been thought to be, but that a grain of gunpowder actually on fire, and burning with the utmoſt violence over the whole of its ſurface, may be projected with ſuch a velocity into a cold atmoſphere, as to extinguiſh the fire, and ſuffer the remains of the grain to fall to the ground unchanged, and as inflammable as before.

This extraordinary fact was aſcertained beyond all poſſibility of doubt by the Count's experiments. Having procured from a powdermill in the neighbourhood of the city of Munich, a quantity of gunpowder, all of the ſame maſs, but formed into grains of very different ſizes, ſome as ſmall as the grains of the fineſt Battel powder, he placed a number of vertical ſcreens of very thin paper, one behind another, at the diſtance of 12 inches from each other; and loading a common muſket repeatedly with this powder, ſometimes without and ſometimes with a wad, he fired it againſt the foremoſt ſcreen, and obſerved the quantity and effects of the unconſumed grains of powder which impinged againſt it. The ſcreens were ſo contrived by means of double frames united by hinges, that the paper could be changed with very little trouble, and it was actually changed after every experiment.

The diſtance from the muzzle of the gun to the firſt ſcreen was not always the ſame; in ſome of the experiments it was only 8 feet, in others it was 10, and in ſome 12 feet.

The charge of powder was varied in a great number of different ways; but the moſt intereſting experiments were made with one ſingle large grain of powder, propelled by ſmaller and larger charges of very fine grained powder.

Theſe large grains never failed to reach the ſcreen; and though they ſometimes appeared to have been broken into ſeveral pieces by the force of the exploſion, yet they frequently reached the ſcreen entire; and ſometimes paſſed through all the ſcreens (five in number) without being broken.

When they were propelled by large charges, and

cateconsequently with great velocity, they were seldom on fire when they arrived at the first screen; which was evident not only from their not setting fire to the paper (which they sometimes did), but also from their being found sticking in a soft board, against which they struck, after having passed through all the five screens; or leaving visible marks of their having been impinged against it, and being broken to pieces and dispersed by the blow. These pieces were often found lying on the ground; and from their forms and dimensions, as well as from other appearances, it was often quite evident that the little globe of powder had been on fire, and that its diameter had been diminished by the combustion before the fire was put out, on the globe being projected into the cold atmosphere.

That these globes or large grains of powder were always set on fire by the combustion of the charge, can hardly be doubted. This certainly happened in many of the experiments; for they arrived at the screens on fire, and set fire to the paper; and in the experiments in which they were projected with small velocities, they were often seen to pass through the air on fire; and when this was the case, no vestige was to be found. They sometimes passed on fire through several of the foremost screens, without setting them on fire, and set fire to one or more of the hindmost, and then went on and impinged against the board, which was placed at the distance of 12 inches behind the last screen.

The Count then proceeds to mention another experiment, in which the progressive combustion of gunpowder was shewn in a manner still more striking, and not less conclusive.

A small piece of red hot iron being dropped down into the chamber of a common horse-pistol, and the pistol being elevated to an angle of about 45 degrees, upon dropping down into its barrel one of the small globes of powder (of the size of a pea), it took fire, and was projected into the atmosphere by the elastic fluid generated in its own combustion, leaving a very beautiful train of light behind it, and disappearing all at once like a falling star. This amusing experiment was repeated very often, and with globes of different sizes. When very small ones were used singly, they were commonly consumed entirely before they came out of the barrel of the pistol; but when several of them were used together, some, if not all of them, were commonly projected into the atmosphere on fire.

As the slowness of the combustion of gunpowder is undoubtedly the cause which has prevented its enormous and almost incredible force from being discovered, our author deduces, as an evident consequence, that the readiest way to increase its effects, is to contrive matters so as to accelerate its inflammation, and combustion. This may be done in various ways; but, in his opinion, the most simple and most effectual manner of doing it would be to set fire to the charge of powder, by shooting (through a small opening) the flame of a smaller charge into the midst of it.

He contrived an instrument on this principle for firing cannon three or four years ago; and it was found, on repeated trials, to be useful, convenient in practice, and not liable to accidents. It likewise supersedes the necessity of using priming, of vent-tubes, port-fires, and matches, and on that account he imagined it might be of use in the British navy, but it does not appear to have been received into practice.

Another infallible method of increasing very considerably the effect of gunpowder in fire-arms of all sorts and dimensions, would be to cause the bullet to fit the bore exactly, or without windage, in that part of the bore at least where the bullet rests on the charge; for, when the bullet does not completely close the opening of the chamber, not only much of the elastic fluid, generated in the first moment of the combustion of the charge, escapes by the side of the bullet; but what is of still greater importance, a considerable part of the unconsumed powder is blown out of the chamber along with it in a state of actual combustion, and, getting before the bullet, continues to burn on as it passes through the whole length of the bore; by which the motion of the bullet is much impeded.

The loss of force which arises from this cause, is in some cases almost incredible; and it is by no means difficult to contrive matters so as to render it very apparent, and also to prevent it.

If a common horse-pistol be fired with a loose ball, and so small a charge of powder that the ball shall not be able to penetrate a deal board so deep as to stick in it when fired against it from the distance of six feet; the same ball, discharged from the same pistol with the same charge of powder, may be made to pass quite through one deal board, and bury itself in a second placed behind it, merely by preventing the loss of force which arises from what is called windage, as he found more than once by actual experiment.

The Count has in his possession a musket, from which, with a common charge of powder, he fires two bullets at once with the same velocity that a single bullet is discharged from a musket on the common construction with the same quantity of powder. And, what renders the experiment still more striking, the diameter of the bore of his musket is exactly the same as that of a common musket, except only in that part of it where it joins the chamber, in which part it is just so much contracted, that the bullet, which is next to the powder, may stick fast in it. He adds, that though the bullets are of the common size, and are consequently considerably less in diameter than the bore, means are used which effectually prevent the loss of force by windage; and to this last circumstance, he concludes, it is doubtless owing, in a great measure, that the charge appears to exert so great a force in propelling the bullets.

That the conical form of the lower part of the bore where it unites with the chamber has a considerable share in producing this extraordinary effect, is, however, very certain, as he has found by experiment made with a view merely to ascertain that fact.

At the close of the Count's last memoir, we have a computation, designed to shew that the force of the elastic fluid generated in the combustion of gunpowder, enormous as it is, may be satisfactorily explained on the supposition that it depends *solely* on the elasticity of watery vapour, or steam. From experiments made in France in the year 1790, it appears that the elasticity of steam is doubled by every addition of temperature equal to 30° of Fahrenheit's thermometer. As the heat generated in the combustion of gunpowder cannot be less than that of red-hot iron, it may be supposed

Gunpowder ‖ Gut-tie.

pofed equal to 1000° of Fahrenheit's fcale:—but the elaftic force of fteam is juft equal to the mean preffure of the atmofphere, when its temperature is equal to that of boiling water, or to 212° of Fahrenheit's thermometer; confequently $212°+30°=240°$ will reprefent the temperature, when its elafticity will be equal to the preffure of two atmofpheres; and, purfuing the calculation, at 602° or 2° above the heat of boiling linfeed oil, its elafticity will be equal to the preffure of 8192 atmofpheres, or above *eight times* greater than the utmoft force of the fluid generated in the combuftion of gunpowder, according to Mr Robins's computation: but the heat in this cafe is much greater than that of 602° of Fahrenheit; and therefore the elafticity of the fteam generated from the water contained in the powder muft be much greater than the preffure of 8192 atmofpheres. At 722°, the elafticity will be equal to the preffure of 131,072 atmofpheres; and this temperature is lefs than the heat of iron, which is vifibly red-hot in daylight, by 355°:—but the flame of gunpowder has been found to melt brafs, which requires a heat equal to that of 3807° of Fahrenheit; 2730° above the heat of red-hot iron, or 3805° higher than the temperature which gives to fteam an elafticity equal to the preffure of 131,072 atmofpheres. That there is in gunpowder water fufficient for fupplying the neceffary quantity of fteam, the author has very fatisfactorily evinced: but we muft not purfue his curious inveftigations any farther. Thofe who want a fuller account of them, will find it either in the original memoirs themfelves, or in a very accurate abridgement of thefe memoirs in the firft volume of Nicholfon's *Journal of Natural Philofophy*, &c.

We cannot conclude this article without mentioning a new kind of gunpowder, invented fome years ago in France, in which the marine acid is fubftituted, in equal quantity, for nitre. Dr Hutton tried fome of this new powder which was made at Woolwich, and found it of about double the ftrength of the ordinary fort; but it is not likely to come into common and general ufe, for the preparation of the acid is difficult and expenfive, (See Chemistry-*Index* in this *Suppl.*), and the powder which is made of it catches fire and explodes from the fmalleft degree of heat, and without the aid of a fpark. It is to this circumftance, however, that its fuperior ftrength feems to be in a great meafure owing.

Gunpowder, a river of the weftern fhore of Maryland, whofe chief branches unite a little above Joppa, and empty into Chefapeak Bay, about 12 miles above Patapfco river. It is navigable only a few miles, by reafon of falls.—*Morse*.

Gunpowder Neck, near the head of Chefapeak Bay, is a curious peninfula formed by Gunpowder river, and Bufh river.—*ib.*

GUNTER's Chain. See Geometry, *Encyclopædia*, Part II. chap. 1.

GUT-tie, a dangerous difeafe to which oxen and male calves are rendered liable by an improper mode of caftration. In fome places, and particularly in Herefordfhire, the breeders of cattle, when they caftrate their calves, open the *fcrotum*, take hold of the tefticles with their teeth, and tear them out with violence; by which means all the veffels thereto belonging are ruptured. The *vafa deferentia*, entering by the holes of the tranfverfe and oblique mufcles into the abdomen, pafs over the ureters in acute angles; at which turning, by their great length and elaftic force, the peritoneum is ruptured; the *vafa deferentia* are fevered from the tefticles, and fpringing back, form a kind of bow from the urethra, where they are united, over the ureters, to the tranfverfe and oblique mufcles, and there again unite, where they firft entered the abdomen; the part of the gut that is tied is the jejunum, at its turning from the left fide to the right, and again from the right to the left, forming right angles under the kidney, and attached to the duplicature of the peritoneum, to which it was united, where the rupture happened. There the bow of the gut hangs over the bow of the *vafa deferentia*, which, by a fudden motion, or turn of the beaft, form a hitch or tie of the ftring round the bow of the gut (filled with air), fimilar to what a carter makes on his cart line. This caufes a ftoppage in the bowels, and brings on a mortification, which, in two days, or four at moft, proves fatal: And to this accident is the beaft, when caftrated as above, liable from the day that he was caftrated till the time of his being flaughtered.

The fymptoms of the gut-tie are the fame as thofe of an incurable colic, *volvulus*, or mortification of the bowels. The beaft affected with this complaint will kick at its belly, lie down, and groan; it has alfo a total ftoppage in its bowels (except blood and mucus, which it will void in large quantities), and a violent fever, &c. To diftinguifh with certainty the gut-tie from the colic, &c. the hand and arm of the operator muft be oiled, and introduced into the anus, through the rectum, beyond the os pubis, turning the hand down to the tranfverfe and oblique mufcles, where the veffels of the tefticles enter the abdomen. There the ftring will be found united to the mufcles, and is eafily traced to the ftricture by the hand, without pain to the beaft.

From the general view of the agriculture of the county of Hereford, drawn up by Mr Clark of Builth, Breconfhire, we learn that Mr Harris farmer at Wickton, near Leominfter, had been uncommonly fuccefsful in the cure of the gut-tie. That gentleman informs us, that he had cut cattle for this difeafe from the age of three months to that of nine years; and as it is a matter of great importance, we fhall ftate his method of operating in his own words.

"The only method of cure (fays he) that can be fafely ventured upon is, to make a perpendicular incifion, four inches under the third vertebra of the loins, on the left fide, over the paunch or ftomach, and introduce the arm to find the part affected; if poffible, keep the beaft ftanding by the help of proper affiftants. The knife I make ufe of to fever the ftring is in the form of a large fifh hook, with an edge on the concave fide; it is fixed to a ring, which fits the middle finger, which finger crooks round the back of the knife, the end of the thumb being placed on its edge. The inftrument, by being thus held in the hand, is fecured from wounding the furrounding inteftines: with it I divide the ftring or ftrings, and bring out one or both as circumftances require. Here it is to be obferved, that great care muft be taken by the operator not to wound or divide the ureters, which would be certain death. I then few up the divided lips of the peritoneum very clofe, with a furgeon's needle threaded with ftrong thread, eight or ten double, fufficiently waxed;

I alfo

I alſo ſew up the ſkin, leaving a vacancy at the top and bottom of the wound ſufficiently wide to introduce a tent of ſurgeon's tow, ſpread with common digeſtive and traumatic balſam; covering the inciſion with a plaſter made of the whites of eggs and wheat flour. The wound, thus treated and dreſſed every day, will be well in a fortnight. The medicine I give to remove the ſtoppage in the three ſtomachs occaſioned by the tie, and to carry off the fever, is four ounces of Glauber's ſalt, two ounces of cream of tartar, and one ounce of ſenna, infuſed in two pounds of boiling water, adding half a pound of olive-oil, and working it off with plenty of gruel, mixed with a large quantity of infuſion of mallows and elder-bark. I adminiſter the gruel and infuſion for at leaſt two or three days; by which time the beaſt will be well, will eat his provender, and chew the cud, and will for ever be relieved, and remain ſafe from this fatal diſorder.

"The following ſimple and eaſy method of caſtration will effectually prevent the gut tie. Open the ſcrotum, looſen out the teſticles, and tie the ſeveral veſſels with a waxed thread or ſilk; or ſear them with a hot iron, to prevent their bleeding, as in the common way of cutting colts. This method can never diſplace the veſſels of the teſticles, bladder, kidneys, or inteſtines; all of which remain covered or attached to the peritoneum, or lining of the abdomen of the beaſt, which renders it impoſſible that there ſhould ever be a ſtricture or tie on the gut."

GUZ, an Indian meaſure, varying in different places, but which may be reckoned about an Engliſh yard. The guz of Akbar was 41 fingers.

H.

HACHA, Rio de la, or *La Hacha*, a province, its chief town, and a river, in Terra Firma or Caſtile del Oro, in South-America. The province is ſurrounded on two ſides by the ocean, viz. on the N. and N. W. and on the third eaſtward by the gulf of Venezuela. The town is ſituated at the mouth of the river, and on its weſt ſide, on a little hill about a mile from the ſea. The ſoil about it is very rich, and abounds with productions common to the climate, alſo European plants and fruits; well ſupplied with ſalt ſprings, veins of gold, and ſome gems of great value. The harbour is none of the beſt, being expoſed to the north winds. It is about 8 leagues from New-Salamanca, and 18 from Cape Vela, N. by E. and 246 miles eaſt of Carthagena. Here the Spaniſh Galleons touch at their arrival in South-America, from whence expreſſes are ſent to all the ſettlements, to give them notice of it. In 1595 it was ſurpriſed and ſacked by Sir Francis Drake. N. lat. 11° 30′, W. long. 72°.—*Morſe.*

HACKETSTOWN, a ſmall poſt-town in Suſſex county, New-Jerſey, on the north-weſt ſide of Muſconecunk river. It is about three miles above the mineral ſpring near Roxbury, on the oppoſite ſide of the river, 22 miles W. by N. of Morriſtown, 16 S. W. by W. of Suſſex court-houſe, and 120 N. N. E. of Philadelphia.—*ib.*

HACKINSACK, a river of New-Jerſey which riſes in New-York, and runs a ſoutherly courſe four or five miles weſt of Hudſon's river. It unites with Paſſaic river at the head of Newark bay, and is navigable about 15 miles.—*ib.*

Hackinsack, the chief town in Bergen county, New-Jerſey, is ſituated near the weſt bank of the above river, 20 miles North-weſt of New-York city. The inhabitants are moſtly Dutch. The houſes are chiefly built of ſtone, in the old Dutch taſte. Here are four public buildings, a Dutch and Epiſcopal church, a court-houſe, and a flouriſhing academy. The people, who are moſtly farmers, carry their produce to New-York.—*ib.*

HADDAM, a town of Connecticut, the ſecond in rank in Middleſex county, ſituated on the weſt ſide of Connecticut river, 18 or 20 miles from its mouth, and 10 miles ſouth-eaſt of the city of Middletown. This townſhip, including Eaſt-Haddam, on the oppoſite ſide of the river, was purchaſed of the Indians, May 20th, 1662. A ſpot in Eaſt-Haddam was famous for Indian *Pawaws*, and was ſubject for many years to earthquakes and various noiſes, which the firſt ſettlers, agreeable to the ſuperſtitious ideas of that age, attributed to theſe *Pawaws*. An old Indian being aſked what was the reaſon of ſuch noiſes in this place? anſwered, The Indian's God was very angry becauſe the Engliſhmen's God came here." Theſe noiſes are now frequently heard.—*ib.*

HADDONFIELD, a ſmall town in Glouceſter county, New-Jerſey, 9 miles S. E. by E. of Philadelphia, and 17 from Burlington.—*ib.*

HADLEY, a pleaſant town in Hampſhire county, Maſſachuſetts, lying on the eaſt ſide of Connecticut river, nearly oppoſite to Northampton, 20 miles north of Springfield, and 97 weſt of Boſton. The town conſiſts of two long ſpacious ſtreets, which run parallel with each other, and with the river. The townſhip contains 882 inhabitants.—*ib.*

HAGARSTOWN, now called *Elizabeth-Town.* It has a conſiderable trade with the weſtern country, and has between two and 300 houſes. It is ſituated in Waſhington county, Maryland; it is a poſt-town 26 miles north-weſt of Fredericktown, 73 N. W. by W. of Baltimore, and 22 S. by W. of Chamberſburg in Pennſylvania.—*ib.*

HALBUT POINT, the north east point of Cape Anne, in Massachusetts.—*Morse.*

HALF MOON, an extensive township in Albany county, New-York. It contains 3,600 inhabitants; of these, 128 are slaves, and 563 are qualified electors. *Waterford*, a neat, compact, thriving village of about 70 or 80 houses, two miles E. N. E. of the Cohoez, and 12 miles north of Albany, on the north bank of the most northerly branch of Mohawk river and on the west bank of the Hudson, is situated in this township.—*ib.*

HALIFAX, a county in the eastern part of the British province of Nova-Scotia. It contains Halifax, the capital; the townships of Londonderry, Truro, Onslow, Colchester, Lawrence, Southampton, Canso, and Tinmouth. The inhabitants are chiefly Irish, Scotch, and New-Englanders. It has numerous bays, and rivers; the chief of the latter are Shabbennacadie, which is a boatable river, the Petitcodiac, Memramcook, &c.—*ib.*

HALIFAX, the capital of the province of Nova Scotia, in the county of its name, was settled by a number of British subjects in 1749. It is situated on a spacious and commodious bay or harbour, called Chebucto, of a bold and easy entrance, where a thousand of the largest ships might ride with great convenience and safety. The town is built on the west side of the harbour, on the declivity of a commanding hill, whose summit is 236 feet perpendicular from the level of the sea. The town is laid out into oblong squares; the streets parallel and at right angles. The town and suburbs are about two miles in length; and the general width a quarter of a mile. It contained in 1793 about 4000 inhabitants and 700 houses. At the northern extremity of the town, is the king's naval yard, completely built and supplied with stores of every kind for the royal navy. The harbour of Halifax is reckoned inferior to no place in British America for the seat of government, being open and accessible at all seasons of the year, when almost all other harbours in these provinces are locked up with ice; also from its entrance, situation, and its proximity to the bay of Fundy, and principal interior settlements of the province.

This city, lying on the south coast of Nova Scotia, has communication with Pictou, 68 miles to the north-east on the gulf of St. Lawrence, by a good cart-road, finished in 1792. It is twelve miles northerly of Cape Sambro, which forms in part the entrance of the bay; 27 south-easterly of Windsor, 40 N. by E. of Truro, 80 N. E. by E. of Annapolis on the bay of Fundy, and 157 south-east of St. Ann, in New-Brunswick, measuring in a straight line. N. lat. 44° 40′ W. long 63° 15′.—*ib.*

HALIFAX, a fort in the town of Winslow, in Lincoln county, Maine, erected by order of Governor Shirley in 1754. It stands on the point of land formed by the confluence of the Sebasticook with the Kennebeck, 30 miles below Sandy river.—*ib.*

HALIFAX, a township in Windham county, Vermont, 23 miles E. by S. of Bennington, has Marlborough on the north, and the Massachusetts line south. It contains 1309 inhabitants.—*ib.*

HALIFAX, a township in Plymouth county, Massachusetts, situated 35 miles south-east of Boston. It was incorporated in 1734, and contains 664 inhabitants.—*ib.*

HALIFAX, a village or settlement on the east side of Susquehannah river, in Dauphin county, Pennsylvania, 13 miles north of Harrisburg.—*ib.*

HALIFAX, one of the middle districts of North-Carolina, bounded north by the State of Virginia, east by Edenton district, west by Hillsborough, and south by Newbern. It is divided into 7 counties, viz. Northampton, Halifax, Martin, Edgecomb, Warren, Franklin, and Nash, which contain 64,630 inhabitants, including 25,402 slaves. Besides smaller streams, the Roanoke passes through this district in a south-east course, and the Pamplico has its source in it. Chief town, Halifax.—*ib.*

HALIFAX, a county of the above district, bounded north by Northampton, south by Edgcomb, east by Bertie, and west by Warren. It contains 7459 inhabitants, and 6506 slaves. Chief town, Halifax.—*ib.*

HALIFAX, the chief town of the above county, and of the district of its name in North-Carolina, is a post-town, pleasantly situated on the western bank of the Roanoke, about six miles below the falls, regularly laid out, and besides dwelling houses, has a court-house and gaol. It is 36 miles north of Tarborough, 28 miles from Grenville court house, 147 north-east of Fayetteville, 75 S. by W. of Petersburg, Virginia, and 393 S. W. by S. of Philadelphia. N. lat. 36° 13′.—*ib.*

HALIFAX, a county in Virginia, bordering on the State of North-Carolina. It is about 42 miles long and 39 broad, and contains 14,722 inhabitants, including 5565 slaves.—*ib.*

HALLOWELL, a flourishing post-town in the District of Maine, and the shire town of Lincoln county, situated in N. lat. 44° 16′, at the head of the tide waters on the west side of Kennebeck river. An academy is established here with a considerable fund in lands. The court-house here is 12 miles S. by W. of Vassalborough, 30 N. by W. of Wiscasset, 40 north-east of New-Gloucester, and 195 N. by E. of Boston. *Hallowell Hook* lies on the same side of the river, three miles below the town, and five north of Pittston. The whole township contains 1194 inhabitants.—*ib.*

HAMBATO, a principal asiento or jurisdiction in the province of Quito, in Peru. It is situated in 1° 41′ S. lat. and 12 miles west of the city of Quito; and has 6 small villages in its dependence. It contains about 18,000 inhabitants, who are mostly employed in weaving stuffs, and in knitting.—*ib.*

HAMBDEN, or *Hamden*, a township in New-York State, bounded north by land ceded to Massachusetts, south by the north line of Pennsylvania, and east by Sidney. Susquehannah river passes in a west course through both towns. The centre of the town lies 13 miles W. by S. of the mouth of Chenengo river.—*ib.*

HAMBURG, a small post town of New-Jersey, 18 miles from Goshen in New-York, and 20 from Newtown or Sussex court house.—*ib.*

HAMBURG, a handsome town in Burke's county, Pennsylvania, seated on the east side of Schuylkill. Here are about 50 or 60 houses, a German Lutheran and Calvinist church united. It is 18 miles N. by W. of Reading, and 70 north-north-west of Philadelphia. North lat. 40° 34′, west long. 76°.—*ib.*

HAMDEN, a township in New-Haven county, Connecticut, about eight miles north of New-Haven city.—*ib.*

HAMILTON, a cape on the north end of Newfoundland island —*ib.*

HAMILTON. There are three townships of this name in Pennsylvania; one in each of the counties of York, Franklin, and Northampton.—*ib.*

HAMILTON, a settlement in Vermont on the Canada line.—*ib.*

HAMILTON, in Herkemer county, New-York, a township 12 miles square, 20 south of old Fort Schuyler, a level township of good land, fast settling.—Oriskè or Olhiske creek, a water of Mohawk, and Chenung, a water of Susquehannah, rise in this township. In 1796 there were 1202 inhabitants, of whom 196 were electors.—*ib.*

HAMILTON, a town or settlement lately laid out in Albany county, New-York, in the extensive township of Water Vliet, formerly called the *Glass Factory;* and has its present name in honour of that great patron of American manufactures, the late secretary of the treasury of the United States of America. It lies 10 miles west of Albany, two miles from the Schenectady road; and is one of the most decisive efforts of private enterprize in the manufacturing line, as yet exhibited in the United States. The glass manufactury is now so well established, and so happily situated for the supply of the northern and western parts of the State of New-York, as well as Vermont and Canada, that it is to be expected the proprietors will be amply rewarded for their great and expensive exertions. The glass is in good reputation. Here are two glass houses, and various other buildings, curious hydraulic works, to save manual labour, by the help of machinery. A copious stream runs through the heart of the settlement which lies high; and being surrounded by pine plains, the air is highly salubrious. The great Schoharie road traverses the settlement. A spacious schoolhouse, and a church of an octagon form are soon to be erected.

In the neighbourhood of these glass works, a block was cut out of an ancient tree, not many years ago, containing evident marks of an axe or some edge tool, made 185 years ago, determined according to the usual and certain mode of ascertaining the age of trees. The block is preserved in Albany as a curiosity. Henry Hudson ascended the river which bears his name, as high as Albany, in the autumn of 1609, 187 years ago, and these marks were probably made by some of his men.—*ib.*

HAMILTON FORD lies near the mouth of Bullock's Creek in North-Carolina. This was the route pursued by Tarleton, after his defeat at Cowpens, in January, 1781.—*ib.*

HAMILTON, a district in the State of Tennessee, situated on the waters of the Holston and Clinch; bounded south by Tennessee river, and separated from Mero district on the west by an uninhabited country. It contains the counties of Knox, Jefferson, Blount, Sevier and Grainger.—*ib.*

HAMILTON, a county of the N. W. Territory, erected Jan. 2, 1790, "beginning on the bank of the Ohio river, at the confluence of the Little Miami; and down the said Ohio river to the mouth of the big Miami, and up said Miami to the Standing Stone Forks, or branch of said river; and thence with a line to be drawn due E. to the Little Miami, and down said little Miami river, to the place of beginning."—*ib.*

HAMILTON FORT, stands on the east side of the Great Miami, in the N. W. Territory; 25 miles south of Fort St. Clair, and 25 north of Cincinnati. It is a stockaded fort, capable of containing 200 men. The situation is as advantageous for defence as pleasing to the eye. It is built upon a narrow neck of land, commanding the Miami on the north-west, and a praire and sheet of water on the north-east, about a mile wide, and 2¼ miles long. The soil near it is rich and fertile; and forage may be got by repeated mowings of natural grass.—*ib.*

HAMILTON, a port in the Bermuda Islands.—*ib.*

HAMMEL'S TOWN, a town in Dauphine county, Pennsylvania, five miles from Susquehannah river, and 85 from Philadelphia. It contains a German church, and about 35 dwelling houses.—*ib.*

HAMPSHIRE, an extensive, populous, and wealthy county in Massachusetts, made a shire in 1662. It is in many parts mountainous and hilly, and extends across the State from north to south; bounded north by the States of New-Hampshire and Vermont, south by the State of Connecticut, east by Worcester county, and west by Berkshire. It contains 60 townships, 9181 houses, 9617 families, and 59,681 inhabitants. Its principal towns lie on both sides of Connecticut river, which intersects it from north to south. These are Springfield, West Springfield, Northampton, Hadley, Hatfield, Deerfield, and Northfield. It is generally of a fertile soil, and produces the necessaries of life, and some of its luxuries in great plenty.—*ib.*

HAMPSHIRE, a county in Virginia, bounded N. and N. W. by the Patowmack river, which divides it from the State of Maryland. It is about 60 miles long and 50 broad, and contains 7346 inhabitants, including 454 slaves. It is well watered by Patowmack and its south branch. Iron ore and coals have been discovered on the banks of this river. Chief town, Romney.—*ib.*

HAMPSTEAD, a town in Rockingham county, New-Hampshire, about 34 miles westerly of Portsmouth. It was incorporated in 1749, and contained in 1775, 768 inhabitants; in 1790, 724.—*ib.*

HAMPSTEAD, a town on Long Island, New-York, nine miles easterly of Jamaica, and 23 miles eastward of New-York city. In this town is an extensive and remarkable plain called *Hampstead Plain.*—*ib.*

HAMPSTEAD, a village in Georgia, about four miles from Savannah, and about a mile from another village called Highgate. The inhabitants are gardeners, and supply the town with greens, pot herbs, roots, &c.—*ib.*

HAMPTON, a township in Windham county, Connecticut, three miles north-east of Windham, of which it was formerly a parish, but lately incorporated.—*ib.*

HAMPTON, EAST, a township in Hampshire county, Massachusetts, containing 457 inhabitants, and situated 105 miles west of Boston. It was incorporated in 1785.—*ib.*

HAMPTON, EAST, on the east end of Long-Island, (New-York) a half shire town of Suffolk county. It has 3260 inhabitants; and in it is Clinton Academy, which in 1795 had 92 students.—*ib.*

HAMPTON, a township on the sea coast of New-Hampshire,

Hampshire, on the eastern side of Rockingham county, and called *Winicumet* by the Indians. It was settled under Massachusetts, and incorporated in 1638. In 1775 it contained 862 inhabitants, and in 1790, 853. It is 12 or 14 miles S. by W. of Portsmouth, and 8 south-east of Exeter. In 1791, a canal was cut through the marshes in this town, which opens an inland navigation from Hampton through Salisbury into Merrimack river for about eight miles; loaded boats may pass through it with ease and safety.—*ib.*

HAMPTON FALLS, a small town taken from the above town, lying on the road which leads from Exeter to Newbury-Port, six miles south easterly of the former, and eight northerly of the latter. In 1775 it contained 645, and in 1790, 541 inhabitants. It was incorporated in 1712.—*ib.*

HAMPTON, a township in the northern part of Washington county, New-York, having Skeensborough on the west. It has 463 inhabitants, of whom 107 are electors.—*ib.*

HAMPTON, the capital of Elizabeth county, in Virginia, also a port of entry, and post town, situated at the head of a bay which runs up north from the mouth of James river, called *Hampton Road*, five miles northwest of Point Comfort. It contains about 30 houses, an episcopal church, a court-house and gaol. The value of its exports of grain, lumber, staves, &c. amounted to 41,997 dollars in one year, ending September 30, 1794. This town was anciently called *Kecoughton* by the Indians. It is 18 miles north of Norfolk, 22 south-east of Yorktown, 93 east-south east of Richmond, and 205 W. by S. of Philadelphia.—*ib.*

HANCES, HANCHES, HAUNCHES, or *Hanses*, in architecture, are certain small intermediate parts of arches between the key or crown and the spring at the bottom, being perhaps about one-third of the arch, and situated nearer the bottom than the top or crown; and are otherwise called the *spandrels*. See ARCH in this *Supplement*.

HANCOCK's HARBOUR, called by the Indians *Clioquot*, is situated about 20 leagues east-south-east of Nootka, in N. lat. 48° 30′, west long. from Greenwich 125° 26′. The entrance of this harbour is about five miles in length, and has good anchorage; about it are scattered a number of islands, and several sand-banks or spits. It has also a number of fine coves. The land round the harbour is generally uneven, rocky and mountainous; covered however with pine, fir, spruce, cedar, hemlock, cypress and other trees of a remarkable size. The climate here is much milder than in the same latitude on the eastern side of the continent; the frost in winter being seldom so severe as to prevent vegetation. An easterly wind is considered here is a prognostic of a storm, and west winds bring fair weather. Deer, racoons, wolves, bears, squirrels, martins, land otters, beaver, and wild cats are the animals which inhabit the forests. The amphibious animals are the common seal, and the sea-otter. The skin of the latter is very valuable. The inhabitants are said to be cannibals. This and other places of the same name have their appellation in honour of the late Governor Hancock, of Massachusetts.—*Morse.*

HANCOCK, a river of Washington island, on the north-west coast of North-America, called *Masheet* by the Indians, discovered by Captain Crowell in 1791. It empties into the sea from the north end of the largest island. At its mouth it is nearly two and a half nautical miles wide; and a considerable size ten miles up. It has at its mouth five fathoms water, gradually increasing in breadth; and for 7½ miles up, to Goose Island, has not less than ten fathoms. Captain Ingraham examined it about 12 miles; but by the information of the natives, he judged that it communicates with Skitikiss Bay, or near it, on the east side of the islands. It is by far the most eligible for a new settlement of any place the Captain had seen on the coast. The land is low and apparently very fertile: and the river abounds with salmon. Were a good house erected on some of the pleasant spots it would have every appearance of being long settled. Beautiful bushes and grass occupy the skirts of the woods. The mouth of the river is in north lat. 54° 7′, west long. 131° 54′.—*ib.*

HANCOCK, a township in Addison county, Vermont. —*ib.*

HANCOCK, a large maritime county of the District of Maine, bounded north by Lower Canada, south by the ocean, east by Washington county, and west by Lincoln county. It is 190 miles long from north to south, and nearly 60 broad. It contains 24 townships and plantations; of which Penobscot and Castine are the chief. The number of inhabitants is greatly increased since 1790. At that time there were 9549 souls. It is remarkably well watered by Penobscot river, and its branches, Union river, and other smaller streams. The northern part of the county sends its waters in one stream from numerous branches in a N. E. course to St. John's river. On the sea-coast are many harbours and inlets, hid by a multitude of fertile islands; the largest of these in a S. W. direction from Goldsborough, are Mount Desart, Swan Isles, Vinal Haven, Haut Isle, Deer and Islesborough, all situated in Penobscot Bay. Great part of the county is yet unsettled. The towns along the sea coast, and on the banks of Penobscot and Union rivers, are the most fertile and populous. Castine is the shire town.—*ib.*

HANCOCK, a township in Lincoln county, Maine, embosomed by the Kennebeck and Sebasticook rivers, bounded N. W. by Canaan, and 7 miles north of the confluence of the two rivers. It contains 278 inhabitants.—*ib.*

HANCOCK, a township in Hillsborough county, New-Hampshire, situated between two western branches of Contoocook river, 14 miles east of Keene, and between 60 and 70 W. by S. of Portsmouth. It was incorporated in 1779, and contains 634 inhabitants. —*ib.*

HANCOCK, a long, narrow and mountainous township on the New-York line, in Berkshire county, Massachusetts, having the towns of Lanesborough and Partridgefield on the northward, and Pittsfield on the S. It was incorporated in 1776, has 1211 inhabitants, and lies 20 miles N. by W. of Lenox, and 150 W. of Boston.—*ib.*

HANCOCK, a small post town of Maryland, situated in Washington county, on the N. bank of Patowmack river, between Conolowy and Little Conolowy creeks, about 25 miles S. E. of Bedford in Pennsylvania, 34 N. E. of Old Town in Maryland, and 119 N. W. of Baltimore.—*ib.*

HANCOCK, a new county in the upper diſtrict of Georgia.—*ib.*

HANNAH BAY *Houſe*, a factory of the Hudſon's Bay Company, at the ſouth end of James' Bay in North America, and on the eaſtern ſide of Harricanaw river, 45 miles E. by S. of Mooſe Fort, and 18 below a houſe on the ſame river.—*ib.*

HANNAH'S TOWN, in Weſtmoreland county, Pennſylvania, 4 miles N. N. E. of Greenſburg, and on the road from Bedford to Pittſburg; 54 miles N. W. by W. of the former, and 26 eaſt of the latter.—*ib.*

HANNIBAL, a military townſhip in the State of New-York, on Lake Ontario, 10 miles S. by W. of Fort Oſwego.—*ib.*

HANOVER, a bay in the ſea of Honduras, ſituated on the eaſt ſide of the peninſula of Yucatan, from which it receives the waters of the Rio Honde. The tract of land between the river Honde and the Balize was ceded by the Spaniſh king to the king of Great Britain, at the peace of 1783, for the purpoſe of cutting and carrying away logwood.—*ib.*

HANOVER, a townſhip in Luzerne county, Pennſylvania. Alſo a townſhip in Waſhington county. Eaſt and Weſt Hanover, are two townſhips in Dauphine county in the ſame State.—*ib.*

HANOVER, or *M'Alliſter's Town*, a poſt town in York county, Pennſylvania, ſituated between Cadorus creek, and a branch of Little Conewago, which flows into the Suſquehannah. It contains nearly 300 dwelling houſes, and a German and Lutheran church. It is 7 miles north of the Maryland line, 18 miles ſouth-weſt of York, and 106 W. by S. of Philadelphia.—*ib.*

HANOVER, a townſhip in Plymouth county, Maſſachuſetts, 25 miles S. E. from Boſton, was incorporated in 1727, and contains 1,083 inhabitants.—*ib.*

HANOVER, a poſt-town of New-Hampſhire, ſituated on the eaſt ſide of Connecticut river in Grafton county. *Dartmouth College*, in this town, is ſituated on a beautiful plain, about half a mile, from the river, in 43° 43′ N. lat. and in 72° 14′ W. long. from Greenwich. It derives its name from William Earl of Dartmouth, one of its principal benefactors, and was founded in the year 1769 by the late Dr Eleazer Wheelock. The funds of the college conſiſt chiefly of lands, amounting to about 80,000 acres, which are increaſing in value in proportion to the growth of the country; 1,200 acres lie contiguous to the college; and are capable of the beſt improvement; 12,000 lie in Vermont. A tract of 8 miles ſquare was granted by the aſſembly of New-Hampſhire in 1789. The revenue of the college ariſing from the lands, in 1793, amounted annually to £140. By contracts then made, they would amount, in four years after, to £450; and in 12 years, to 650. The income from tuition is about £600 per annum. The number of under-graduates is, on an average, from 150 to 180. A grammar ſchool of about 50 or 60 ſcholars is annexed to the college. The ſtudents are under the immediate government and inſtruction of a preſident, who is alſo profeſſor of hiſtory, a profeſſor of mathematics, and natural philoſophy, a profeſſor of languages, and two tutors. The college is furniſhed with a handſome library and a philoſophical apparatus tolerably complete. A new college edifice of wood, 150 by 50 feet, and three ſtories high, was erected in 1786, containing 36 rooms for ſtudents. Its ſituation is elevated, healthful and pleaſant, commanding an extenſive proſpect to the weſt. There are three other public buildings, belonging to the college, and a handſome congregational meeting houſe has lately been erected, in which the commencement exerciſes are exhibited. It is 32 miles north of Charleſton, 115 N. W. by W. of Portſmouth, 138 N. W. of Boſton, and 378 N. E. by N. of Philadelphia.—*ib.*

HANOVER, a townſhip in Morris county, New-Jerſey. In a ridge of hills in this townſhip are a number of wells, 40 miles from the ſea in a ſtraight line, which regularly ebb and flow about 6 feet twice in every 24 hours. It is about 16 miles N. W. of Elizabeth-Town, and joins upon Morriſtown.—*ib.*

HANOVER, a county of Virginia, lying between Pamunky and Chickahominy rivers. Its length is about 48 miles, and its breadth 22; and contains 14,754 inhabitants, including 8,223 ſlaves. It abounds with lime-ſtone.—*ib.*

HANOVER, a ſmall town of Virginia, of the above county, ſituated on the weſt ſide of the Pamunky, in which is an academy. It is 6 miles from Newcaſtle, 22 N. E. by E. of Richmond, and 110 N. N. W. of Waſhington city.—*ib.*

HANSPIKE, or HANDSPEC, a lever or piece of ſtrong wood, for raiſing by the hand great weights, &c. It is five or ſix feet long, cut thin and crooked at the lower end, that it may get the eaſier between things that are to be ſeparated, or under any thing that is to be raiſed. It is better than a crow of iron, becauſe its length allows a better poiſe.

HANTS, a county of Nova-Scotia, beginning about 30 miles from Halifax, contains the townſhips of Windſor, Falmouth, and Newport; ſeveral valuable tracts remain unſettled. The road from Halifax runs part of the way between Windſor and Newport, and has ſettlements on it at ſmall diſtances. The county is about 20 miles ſquare, and is well watered. The rivers St. Croix, Kenetcoot, and Cocmiguen empty into the Avon, and are all navigable except the laſt. The Cacaguet and Cobeguit are navigable 40 miles for veſſels of 60 tons.—*Morſe.*

HARDIN, a new county in the State of Kentucky, bounded N. E. by Waſhington and Lincoln, N. W. and W. by Nelſon and Greene, and S. E. by Logan counties.—*ib.*

HARDWICK, a townſhip in Caledonia county, in Vermont.—*ib.*

HARDWICK, a townſhip in Worceſter county, Maſſachuſetts, 25 miles N. W. of Worceſter, and 70 S. W. of Boſton. It is ſeparated from New-Braintree and Ware by Ware river. There are within this town 245 houſes, 1,725 inhabitants, 5 corn and 4 ſaw mills, and two clothiers' works.—*ib.*

HARDWICK, a townſhip in Suſſex county, New-Jerſey, nearly 10 miles S. W. of Newton.—*ib.*

HARDWICK, a ſmall town of Georgia, at the mouth of Ogeeche river, and about 18 miles S. by W. of Savannah. It has lately been made a port of entry.—*ib.*

HARDY, a county of Virginia, bounded north by Hampſhire. It is about 60 miles long, and 40 in breadth, and contains 7,336 inhabitants, including 369 ſlaves. Chief town, Moorfield.—*ib.*

HARDYSTON, a townſhip in Suſſex county, New-Jerſey, containing 2,393 inhabitants, including 26 ſlaves.—*ib.*

HARFORD *County*, in Maryland, is bounded north by York county in Pennſylvania; eaſt by Suſquehannah river and Cheſapeak Bay. The chief waters within the county are Buſh river and Deer creek; on which are 16 mills of different kinds. On the former and its branches are the towns of Harford, Abington, Coopſtown, and Belle-Air. The other towns are Havre de Gras at the mouth of Suſquehannah, and Joppa below the forks of Gunpowder.

It contains 14,976 inhabitants, including 3,417 ſlaves. Chief town, Belle-Air.—*ib.*

Harford, or *Buſh-town*, in Harford county, Maryland, lies at the head of the tide waters of Buſh river, between Binam's and James's runs; the former ſeparating it from Abington. It has few houſes, and is falling to decay ſince the courts of juſtice have been removed to Belle-Air. It is 9 miles S. E. of Belle-Air, and 25 N. E. by E. of Baltimore.—*ib.*

HARLEM, a townſhip in Lincoln county, Maine, incorporated in 1796. It was formerly called *Jones's Plantation.*—*ib.*

Harlem, or *Eaſt River*, a river which connects Long-Iſland Sound with North, or Hudſon river, and forms York-Iſland.—*ib.*

Harlem, a diviſion of New-York county in the northern part of York-Iſland, which contains 803 inhabitants, including 189 ſlaves. The village of its name ſtands 9 miles northerly of New-York city, and 4 S. W. of Weſt-Cheſter. It is oppoſite to the weſt end of Hell Gate.—*ib.*

HARMAN's *Station*, in Kentucky, is a fort on the eaſt ſide of the weſt branch of Big Sandy river. On the oppoſite ſide of this branch is the Great Salt ſpring. Harman's Station is about 20 miles ſouth of Vancouver's fort.—*ib.*

HARMAR, a well conſtructed fort in the N. W. Territory, ſituated at the mouth of the Muſkingum. It has 5 baſtions, and 3 cannon mounted, and is garriſoned by 4 companies. It is conveniently ſituated to reinforce any of the poſts up or down the river Ohio. The place is remarkably healthy.—*ib.*

HARMONY, a village in Luzerne county, Pennſylvania, cloſe on the line of New-York, on the north ſide of Starucca creek, a water of the eaſt branch of Suſquehannah river. Between this and Stockport on Delaware river, diſtant 18 miles E. S. E. there is a portage. It is about 140 miles N. by W. of Philadelphia, and 130 N. W. of New-York. N. lat. 41° 58'.—*ib.*

HARPATH, a ſmall boatable river in Tenneſſee, which, after a N. N. W. courſe of about 40 miles, falls into Cumberland river, 19 miles N. W. of Naſhville.—*ib.*

HARPERSFIELD, a townſhip in Otſego county, in New-York, bounded S. W. by Unadilla townſhip, and 32 miles S. E. of Cooperſtown; 155 of its inhabitants are electors. Through this town runs the great poſt-road from Hudſon to Williamſburgh, 62 miles weſt of Hudſon city.—*ib.*

HARPLE, a townſhip in Delaware county, Pennſylvania.—*ib.*

HARPSWELL, a townſhip in Cumberland county, Diſtrict of Maine, incorporated in 1758, and contains 1071 inhabitants. It is bounded eaſterly by Georgetown; from which it is ſeparated by a navigable river. The people here are opening a communication by a canal between the waters of Kennebeck river and thoſe of Caſco Bay, through the arm of the ſea called Stevens's river. The point called Merryconeag, projecting itſelf into the bay together with the iſland Sebaſcodeagan, and ſeveral other ſmall iſlands, are incorporated and form this townſhip. The waters round this iſland extend to within two miles of the waters of the Kennebeck, and thus form what is called ſmall Point.—*ib.*

HARRINGTON, a townſhip in Bergen county, New-Jerſey.—*ib.*

HARRIOT (Thomas) was a very eminent mathematician of the 16th and 17th centuries, of whom ſome account has been given in the *Encyclopædia.* In that article it has been ſhewn, that Des Cartes had ſeen ſome improvements of Harriot's in algebra, and publiſhed them to the world as his own; but this piece of plagiariſm has been more completely proved in the Aſtronomical Ephemeris for the year 1788, by Dr Zach, aſtronomer to the Duke of Saxe-Gotha; who likewiſe ſhews that Harriot was an aſtronomer as well as an algebraiſt.

"I here preſent to the world (ſays the Doctor) a ſhort account of ſome valuable and curious manuſcripts, which I found in the year 1784 at the ſeat of the earl of Egremont, at Petworth in Suſſex.

"A predeceſſor of the family of lord Egremont, viz. that noble earl of Northumberland, named Henry Percy, was not only a generous favourer of all good learning, but alſo a patron and Mæcenas of the learned men of his age. Thomas Harriot, the author of the ſaid manuſcripts, Robert Hues (well known by his Treatiſe upon the Globes), and Walter Warner, all three eminent mathematicians, who were known to the earl, received from him yearly penſions; ſo that when the earl was committed priſoner to the Tower of London in the year 1606, our author, with Hues and Warner, were his conſtant companions: and were uſually called the earl of Northumberland's three Magi.

"Thomas Harriot is a known and celebrated mathematician among the learned of all nations, by his excellent work. *Artis Analyticæ Praxis, ad æquationes algebraicas nova expedita & generali methodo, reſolvendas, Tractatus poſthumus:* Lond. 1631: dedicated to Henry earl of Northumberland; publiſhed after his death by Walter Warner. It is remarkable, that the fame and the honour of this truly great man were conſtantly attacked by the French mathematicians, who could not endure that Harriot ſhould in any way diminiſh the fame of their Vieta and Des Cartes, eſpecially the latter, who was openly accuſed of plagiariſm from our author.

"Des Cartes publiſhed his Geometry ſix years after Harriot's work appeared, viz. in the year 1637. Sir Charles Cavendiſh, then ambaſſador at the French court at Paris, obſerved to the famous geometrician Roberval, that theſe improvements in analyſis had been already made theſe ſix years in England, and ſhewed him afterwards Harriot's *Artis Analyticæ Praxis*; which, Harriot. as Roverval was looking over, at every page he cried out, *Oui! oui! il l'a vu! Yes! yes! he has seen it!* Des Cartes had also been in England before Harriot's death, and had heard of his new improvements and inventions in analysis.

"Now all this relates to Harriot the celebrated analyst; but it has not hitherto been known that Harriot was an eminent astronomer, both theoretical and practical, which first appears by these manuscripts; among which, the most remarkable are 199 observations of the sun's spots, with their drawings, calculations, and determinations of the sun's rotation about his axis. There is the greatest probability that Harriot was the first discoverer of these spots, even before either Galileo or Scheiner. The earliest intelligence we have of the first discovered solar spots is of one Joh. Fabricius Phrysius, who in the year 1611 published at Wittemberg a small treatise, intitled, *De Maculis in Sole observatis & apparente eorum cum Sole conversione narratio.* Galileo, who is commonly accounted the first discoverer of the solar spots, published his book, *Istoria e Dimonstrazioni intorne alle Machie Solare e loro accidenti*, at Rome in the year 1613. His first observation in this work is dated June 2d 1612. Angelo de Filiis, the editor of Galileo's work, who wrote the dedication and preface to it, mentions, page 3. that Galileo had not only discovered these spots in the month of April in the year 1611, at Rome, in the Quirinal Garden, but had shewn them several months before (*molti-mesi inanzi*) to his friends in Florence; and that the observations of the disguised Apelles (the Jesuit Scheiner, a pretender to this first discovery) were not later than the month of October in the same year; by which the epoch of this discovery was fixed to the beginning of the year 1611. But a passage in the first letter of Galileo's works, pa. 11. gives a more precise term to this discovery. Galileo there says in plain terms, that he had observed the spots in the sun 18 months before. The date of this letter is May 24. 1612; which brings the true epoch of this discovery to the month of November 1610. However, Galileo's first produced observations are only from June 2. 1612, and those of father Scheiner of the month of October in the same year. But now it appears from Harriot's manuscripts, that his first observations of these spots are of Dec. 8. 1610. It is not likely that Harriot could have this notice from Galileo, for I do not find this mathematician's name ever quoted in Harriot's papers: But I find him quoting book i. chap. 2. of Joseph a Costa's *Natural and Moral History of the West Indies;* in which he relates, that in Peru there are spots to be seen in the sun which are not seen in Europe: and hence it is probable, that Harriot took the hint of looking for such spots. Besides, it is not unlikely, that living with so munificent a patron, Harriot got from Holland the new invented telescopes much sooner than they could reach Galileo, who at the time lived at Venice. Harriot's very careful and exact observations of these spots, shew also that he was in possession of the best and most improved telescopes of that time; for it appears he had some with magnifying powers of 10, 20, and 30 times. At least there are no earlier observations of the solar spots extant than his; they run from December 8. 1610, till January 18. 1613. I compared the corresponding ones with these observed by Galileo, between which I found an exact agreement. Had Harriot had any notion about Galileo's discoveries, he certainly would have also known something about the phases of Venus and Mercury, and especially about the singular shape of Saturn, first discovered by Galileo; but I find not a word in all his papers concerning the particular figure of that planet.

"I found likewise, (continues Dr Zach) among the papers of Harriot a large set of observations on the satellites of Jupiter, with drawings of them, their positions, and calculations of their revolutions and periods. His first observation of those discovered satellites, I find to be of January 16. 1610; and they go till February 26. 1612. Galileo pretends to have discovered them January 7. 1610; so that it is not improbable that Harriot was likewise the first discoverer of these attendants of Jupiter.

"Among his other observations of the moon, of eclipses, of the planet Mars, of solstices, of refraction, of the declination of the needle, &c. there are remarkable ones of the comet of 1607, and the latter comet (for there were two) of 1618. They were all observed with a cross-staff, by measuring their distances from fixed stars; whence these observations are the more valuable, as comets had before been but grossly observed. Kepler himself observed the comet of 1607 only with the naked eye, pointing out its place by a coarse estimation, without the aid of an instrument; and the elements of their orbits could, in defect of better observations, be only calculated by them. The observations of the comet of the year 1607 are of the more importance, even now for modern astronomy, as this is the same comet that fulfilled Dr Halley's prediction of its return in the year 1759. That prediction was only grounded upon the elements afforded him by these coarse observations; for which reason he only assigned the term of its return to the space of a year. The very intricate calculations of the perturbations of this comet, afterwards made by M. Clairaut, reduced the limits to a month's space. But a greater light may now be thrown upon this matter by the more accurate observations on this comet by Mr Harriot. In the month of October 1785, when I conversed upon the subject of Harriot's papers, and especially on this comet, with the celebrated mathematician M. de la Grange, director of the Royal Academy of Sciences at Berlin, he then suggested to me an idea, which, if brought into execution, will clear up an important point in astronomy. It is well known to astronomers how difficult a matter it is to determine the mass, or quantity of matter, in the planet Saturn; and how little satisfactory the notions of it are that have hitherto been formed. The whole theory of the perturbations of comets depending upon this uncertain datum, several attempts and trials have been made towards a more exact determination of it by the most eminent geometricians of this age, and particularly by la Grange himself; but never having been satisfied with the few and uncertain data heretofore obtained for the resolution of this problem, he thought that Harriot's observations on the comet of 1607, and the modern ones of the same comet in 1759, would suggest a way of resolving the problem *à posteriori;* that of determining by them the elements of its ellipsis. The retardation of the comet compared to its period, may clearly be laid to the account of the attraction and perturbation it has

has suffered in the region of Jupiter and Saturn; and as the part of it belonging to Jupiter is very well known, the remainder must be the share which is due to Saturn; whence the mass of the latter may be inferred. In consequence of this consideration, I have already begun to reduce most of Harriot's observations of this comet, in order to calculate by them the true elements of its orbit on an elliptical hypothesis, to complete M. de la Grange's idea upon this matter.

"I forbear to mention here any more of Harriot's analytical papers, which I found in a very great number. They contain several elegant solutions of quadratic, cubic, and biquadratic equations; with some other solutions and *loca geometrica*, that shew his eminent qualifications, and will serve to vindicate them against the attacks of several French writers, who refuse him the justice due to his skill and accomplishments, merely to save Des Cartes's honour, who yet, by some impartial men of his own nation, was accused of public plagiarism."

HARRISBURG, a post-town, and the capital of Dauphine county, Pennsylvania, is situated on the N. E. bank of Susquehannah river. It is laid out regularly, and contains about 300 houses; of which several are neat and convenient; some of brick and others of stone. In 1789, it contained 130 houses, a stone gaol, and a German church. At that period it had been settled about 3 years. It is 107 miles W. N. W. of Philadelphia, 53 W. S. W. of Reading, and 17 E. N. E. of Carlisle. N. lat. 40° 16′.—*Morse*.

HARRISON, a township in West-Chester county, New-York, containing 1004 inhabitants; of whom 115 are electors, and 54 slaves.—*ib.*

HARRISON, a county in the western part of Virginia, bounded N. by Ohio county, N. E. by Monongalia, S. by Greenbriar, and S. W. by Kenhawa. Its length is about 120 miles, its breadth 80; and the number of inhabitants 2,080, including 67 slaves. Chief town Clarksburg.—*ib.*

HARRISON, a new county in the N. E. part of the State of Kentucky, N. of Bourbon.—*ib.*

HARRODSBURG, or *Harrodstown*; a post-town in Mercer county, Kentucky, at the head of Salt river, which contains about 20 houses, and is 10 miles S. W. of Danville, 30 S. by W. of Frankfort, and 825 S. W. of Philadelphia.—*ib.*

HARTFORD, a township in Windsor county, Vermont, on Connecticut river, opposite the town of Lebanon, in New-Hampshire. It contains 988 inhabitants.—*ib.*

HARTFORD, a township on the east bank of Genessee river, in New-York State, 40 miles W. of Geneva, and 67 S. E. by E. of Fort Niagara.

HARTFORD, a fertile and populous, though hilly county, in Connecticut, bounded N. by the State of Massachusetts; S. by part of Middlesex and New-Haven counties; E. by Tolland, and W. by Litchfield county. It is about 34 miles from N. to S. and its greatest breadth from E. to W. is 30 miles. It is divided into 15 townships, and contains 38,029 inhabitants, including 263 slaves. Chief town, Hartford city.—*ib.*

HARTFORD *City*, the capital of Connecticut, lies on the west bank of Connecticut river, in the county and township of its own name, 50 miles north-westerly from the mouth of the river, at Saybrook Bar, in Long Island Sound; and thus far the tide flows. The township is 6 miles square, bounded N. by Windsor, N. E. by East-Windsor, W. by Farmington, E. by East-Hartford, S. E. by Glastenbury, and S. by Wethersfield. The town is divided by a small stream called Little River, with high romantic banks, over which is a bridge connecting the two divisions of the town. The city is regularly laid out, the streets intersecting each other at right angles. Its buildings are an elegant state-house, lately built, 2 churches for Congregationalists, 1 for Episcopalians, and between 400 and 500 dwelling-houses; a number of which are handsomely built with brick. The inhabitants amount to upwards of 4,000. A bank was incorporated in 1792, with 100,000 dollars capital, number of shares 250. The corporation have the power to extend their capital to 500,000 dollars. A woollen manufactory was established here and encouraged by the State, but has not succeeded. The town is advantageously situated for trade, has a fine back country, enters largely into the manufacturing business, and is a rich, flourishing, commercial town.

This town was first settled in the year 1636, by Mr Haynes and Mr Hooker, who, with their adherents, removed from Massachusetts. The Dutch had then a trading house at the confluence of Mill and Connecticut rivers. They soon relinquished the settlement, and their lands were confiscated by a commission from the Commonwealth of England in 1653. A point of land, which formed part of their possessions, is still called Dutch Point. It is 40 miles N. E. by N. of New-Haven, 55 N. W. of New-London, 124 S. W. of Boston, 128 N. E. of New-York, 223 N. E. of Philadelphia, 502 from Richmond, 376 from Washington city, 1044 from Augusta, and 1018 from Frankfort in Kentucky. N. lat. 41° 44′, W. long. 73° 4′.—*ib.*

HARTLAND, a township of Connecticut, the north-easternmost in Litchfield county.—*ib.*

HARTLAND, a township in Windsor county, Vermont, situated on the west bank of Connecticut river, 11 miles below the 15 mile Falls.—*ib.*

HARVARD, a township in the eastern part of Worcester county, Massachusetts, 23 miles N. E. of Worcester, and 35 north easterly of Boston. It was incorporated in 1732, by this name, in honour of the founder of Harvard University in Cambridge. It has 1400 inhabitants.—*ib.*

HARWICH, a township on Cape Cod, in Barnstable county, Massachusetts, lying between Yarmouth and Chatham, about 88 miles S. E. of Boston, containing 2392 inhabitants. It extends quite across the cape, which is here about 6 miles over. Their marine business lies chiefly in the fishery. The remains of the Indians of this township are only 6 or 7 souls. They live at *Potanumaquut*.—*ib.*

HARWICH, a township in Rutland county, Vermont, containing 165 inhabitants.—*ib.*

HARWINGTON, a post town of Connecticut, in Litchfield county, 8 miles E. of Litchfield, and 24 W. by N. of Hartford.—*ib.*

HASSELQUIST (Frederick) was born in the province of East Gothland in 1722, and studied medicine and botany in the university of Upsal. Linnæus had in his lectures represented the extraordinary merits and

Hasselquist. and great celebrity which a young student might obtain by travelling through Palestine, and by inquiring into and describing the natural history of that country, which was till then unknown, and had become of the greatest importance to interpret the bible, and to understand eastern philology. Hasselquist was fired with ambition to accomplish an object so important in itself, and so warmly recommended by his beloved master. There being no fund arising from the liberality of the crown, private collections were made, which poured in very copiously, especially from the native country of the young traveller. All the faculties of the university of Upsal also granted him a stipend.

Thus protected, he commenced his journey in the summer of 1749. By the interference of Lagerstroem, he had a free passage to Smyrna in one of the Swedish East Indiamen. He arrived there at the conclusion of the year, and was received in the most friendly manner by Mr A. Rydel, the Swedish consul. In the beginning of 1750 he set out for Egypt, and remained nine months at Cairo the capital. Hence he sent to Linnæus, and to the learned societies of his country, some specimens of his researches. They were published in the public papers, and met with the greatest approbation; and upon the proposition of Dean Baeck and Dr Wargentin, secretary of the Royal Academy of Sciences, a collection of upwards of 10,000 dollars in copper money was made for the continuance of the travels of young Hasselquist. Counsellors Lagerstroem and Nordencrantz were the most active in raising subscriptions at Stockholm and Gothenburgh. In the spring of 1751, he repaired to his destination, and passed through Jaffa to Jerusalem, Jericho, &c. He returned afterwards through Rhodus and Scio to Smyrna. Thus he fulfilled all the expectations of his country, but he was not to reap the reward of his toils. The burning heat of the sandy deserts of Arabia had affected his lungs; he reached Smyrna in a state of illness, in which he languished for some time, and died February 9. 1752, in the 30th year of his age.

The fruits of his travels were, however, preserved through the liberality of a great princess. He had been obliged to contract debts. The Turks, therefore, seized upon all his collections, and threatened to expose them to public sale. The Swedish consul prevented it. He sent, with the intelligence of the unhappy exit of his countryman, an account of the distresses under which he died;—and at the representation of Dean Baeck, Queen Louisa Ulrica granted the sum of 14,000 dollars in copper specie to redeem all his collections. They arrived afterwards in good preservation at Stockholm; consisting of a great quantity of antiques, Arabian manuscripts, shells, birds, serpents, insects, &c. and were kept in the cabinets at Ulrichsdale and Drottningholm. The specimens of the natural curiosities of these museums being double or treble in number, Linnæus obtained some of them, and published the voyage of his ill-fated friend, and honoured his memory with a plant, which he called from his name *Hasselquistia*. Hasselquista, *Encycl.*

Hat-making. HAT-MAKING is a mechanical process, which is detailed in the *Encyclopædia* from the best information that could then be obtained. We have lately learned, however, that our detail is sometimes defective, and sometimes erroneous; and it is our duty to supply those defects, and to correct these errors. But, strangers as we are to the business of hat-making, we should not perhaps have suspected, that we had been misled by the persons whom we consulted, had we not been informed by a very intelligent writer in Nicholson's Philosophical Journal, that the account of the manufacturing of hats, which is given in the *Encyclopædia* is far from the truth. This information induced us to look through the Journal itself for a more accurate account of the process; well convinced, that the liberal-minded author of that work would not have pointed out our mistakes without making us welcome to avail ourselves of his aid to correct them. Our readers will therefore be indebted only to Mr Nicholson and his correspondent for whatever instruction they may derive from this article; and as we wish not to deck ourselves in borrowed plumes, we shall communicate that instruction in the words of its author.

Having visited the manufactory of Messrs Collinsons, hatters in Gravel lane, Southwark, Mr Nicholson gives the following account of their procedure:

"The materials for making hats are rabbits fur cut off from the skin, after the hairs have been plucked out, together with wool and beaver. The two former are mixed in various proportions, and of different qualities, according to the value of the article intended to be made; and the latter our author believes to be universally used for facing the finer articles, and never for the body or main stuff. Experience has shewn, that these materials cannot be evenly, and well felted together, unless all the fibres be first separated, or put into the same state with regard to each other. This is the object of the first process, called *bowing*. The material, without any previous preparation (A), is laid upon a platform of wood, or of wire, somewhat more than four feet square, called a *hurdle*, which is fixed against the wall of the work-shop, and is enlightened by a small window, and separated by two side partitions from other hurdles, which occupy the rest of the space along the wall. The hurdle, if of wood, is made of deal planks, not quite three inches wide, disposed parallel to the wall, and at the distance of one fortieth or one fiftieth of an inch from each other, for the purpose of suffering the dust, and other impurities of the stuff, to pass through; a purpose still more effectually answered by the hurdle of wire.

"The workman is provided with a bow, a bow-pin, a basket, and several cloths. The bow is a pole of yellow deal wood, between seven and eight feet long, to which are fixed two bridges, somewhat like that which receives the hair in the bow of the violin (B). Over these

(A) Some writers mention a partial wetting of the fur while on the skin, by lightly smearing it with a solution of nitrate of mercury to give it a curl. Messrs Collinsons do not use it, nor any other preparation.

(B) Mr Nicholson's correspondent, who is himself a hatter, says that a bow is best made of ash; that it is composed of the *stang* or handle; that the bridge at the smaller end, or that which is nearest the window in the act of bowing, is called the *cock*; and that the other bridge, which is nearer to the workman's hand, is called the *breech*.

Hat-making.

these is stretched a catgut, about one-twelfth part of an inch in thickness. The bow-pin is a stick with a knob, and is used for plucking the bow-string. The basket is a square piece of ozier work, consisting of open strait bars with no crossing or interweaving. Its length across the bars may be about two feet, and its breadth eighteen inches. The sides into which the bars are fixed are slightly bended into a circular curve, so that the basket may be set upright on one of these edges near the right hand end of the hurdle, where it usually stands. The cloths are linen. Besides these implements, the workman is also provided with brown paper.

"The *bowing* commences by shovelling the material towards the right hand partition with the basket, upon which, the workman holding the bow horizontally in his left hand, and the bow-pin in his right, lightly places the bow string, and gives it a pluck with the pin. The string, in its return, strikes part of the fur, and causes it to rise, and fly partly across the hurdle in a light open form. By repeated strokes, the whole is thus subjected to the bow; and this beating is repeated till all the original clots or masses of the filaments are perfectly opened and obliterated. The quantity thus treated at once is called a *batt*, and never exceeds half the quantity required to make one hat.

"When the batt is sufficiently bowed, it is ready for *hardening*; which term denotes the first commencement of felting. The prepared material being evenly disposed on the hurdle, is first pressed down by the convex side of the basket, then covered with a cloth, and pressed successively in its various parts by the hands of the workman. The pressure is gentle, and the hands are very slightly moved back and forwards at the same time through a space of perhaps a quarter of an inch, to favour the hardening or entangling of the fibres (See Felting in this *Suppl.*) In a very short time, indeed, the stuff acquires sufficient firmness to bear careful handling. The cloth is then taken off, and a sheet of paper, with its corners doubled in, so as to give it a triangular outline, is laid upon the batt, which last is folded over the paper as it lies, and its edges, meeting one over the other, form a conical cap. The joining is soon made good by pressure with the hands on the cloth. Another batt, ready hardened, is in the next place laid on the hurdle, and the cap here mentioned placed upon it, with the joining downwards. This last batt being also folded up, will consequently have its place of junction diametrically opposite to that of the inner felt, which it must therefore greatly tend to strengthen. The principal part of the hat is thus put together, and now requires to be worked with the hands a considerable time upon the hurdle, the cloth being also occasionally sprinkled with clear water. During the whole of this operation, which is called *basoning* (c), the article becomes firmer and firmer, and contracts in its dimensions. It may easily be understood, that the chief use of the paper, is to prevent the sides from felting together.

"The basoning is followed by a still more effectual continuation of the felting called *working* (d). This is done in another shop, at an apparatus called a *battery*, consisting of a *kettle* (containing water slightly acidulated with sulphuric acid, to which, for beaver hats, a quantity of the grounds of beer is added, or else plain water for rinsing out), and eight *planks* of wood joined together in the form of a frustum of a pyramid, and meeting in the kettle at the middle. The outer or upper edge of each plank is about two feet broad, and rises a little more than two feet and a half above the ground; and the slope towards the kettle is considerably rapid, so that the whole battery is little more than six feet in diameter. The quantity of sulphuric acid added to the liquor is not sufficient to give a sour taste, but only renders it rough to the tongue. In this liquor heated rather higher than unpractised hands could bear, the article is dipped from time to time, and then worked on the planks with a roller, and also by folding or rolling it up, and opening it again; in all which, a certain degree of care is at first necessary, to prevent the sides from felting together; of which, in the more advanced stages of the operation, there is no danger. The imperfections of the work now present themselves to the eye of the workman, who picks out knots and other hard substances with a bodkin, and adds more felt upon all such parts as require strengthening. This added felt is patted down with a wet brush, and soon incorporates with the rest. The beaver is laid on towards the conclusion of this kind of working. Mr Nicholson could not distinctly learn why the beer grounds were used with beaver-hats. Some workmen said, that by rendering the liquor more tenacious, the hat was enabled to hold a greater quantity of it for a longer time; but others said, that the mere acid and water would not adhere to the beaver facing, but would roll off immediately when the article was laid on the plank.

(c) Mr Nicholson's correspondent says, that after bowing, and previous to the basoning, a *hardening skin*, that is, a large piece of skin, about four feet long and three feet broad, of leather alumed or half tanned, is pressed upon the batt, to bring it by an easier gradation to a compact appearance; after which it is basoned, being still kept upon the hurdle. This operation, the basoning, derives its name from the process or *mode of working*, being the same as that practised upon a wool hat after bowing; the last being done upon a piece of cast metal, four feet across, of a circular shape, called *a bason*: the joining of each batt is made good here by thumbling the hand, that is, by rubbing the edges of each batt folded over the other to excite the progressive motion of each of the filaments in felting, and to join the two together. Many journeymen, to hurry this work, use a quantity of vitriol (sulphuric acid), and then, to make the nap rise and flow, they kill the vitriol, and open the body again by throwing in a handful or two of oatmeal; by this means they get a great many made, though, at the same time, they leave them quite grainy from the want of labour. This, in handling the dry grey hat when made may be in part discovered; but in part only.

(d) The intelligent writer, who has been so often quoted, says, that before this operation is begun, the hat is dipped into the boiling kettle, and allowed to lie upon the plank until cold again; this is called *soaking*, that is, being perfectly saturated with the hot liquor: if they are put in too hastily in this state, for they are then only bowed and basoned, they would burst from the edges, each batt not being sufficiently felted into the other.

plank. It is probable, as he observes, that the manufacturers who now follow the established practice, may not have tried what are the inconveniencies this addition is calculated to remove."

Our author's correspondent, however, assigns several reasons for the addition of those dregs, which, he says, ought to be thick, and the sourest that can be got. 1. Vitriol (sulphuric acid) would harden the hat too much, which is kept mellow by the dregs. 2. The dregs are said by the workmen to hold or fill the body, whilst a little vitriol cleanses it of the dirt, &c. that may be on the rabbit or other wools. 3. Another advantage attending the use of dregs, whether of beer, porter, or wine, is, that as the boiling of the dyeing does not draw out much of the mucilage from each hat when it comes to be stiffened, the dregs form a body within the hat, sufficiently strong or retentive to keep the glue from coming through amongst the nap. 4. Vitriol (sulphuric acid) alone purges or weakens the goods too much; consequently half of the quantity does better with the addition of dregs, as it allows the body to be made closer by more work.

Of these four reasons for the use of dregs, the last alone appears to us perspicuous or at all satisfactory. But be this as it may, acid of some kind gives a roughness to the surface of the hair, which facilitates the mechanical action of felting; and Mr Collinson informed Mr Nicholson, that in a process, called *carotting*, they make use of nitrous acid. In this operation, the material is put into a mixture of the nitrous and sulphuric acids in water, and kept in the digesting heat of a stove all night; by which means the hair acquires a ruddy or yellow colour, and loses part of its strength.

"It must be remembered, that our hat still possesses the form of a cone, and that the whole of the several actions it has undergone have only converted it into a soft flexible felt, capable of being extended, though with some difficulty, in every direction. The next thing to be done is to give it the form required by the wearer. For this purpose the workman turns up the edge or rim to the depth of about an inch and a half, and then returns the point back again through the centre or axis of the cap, so far as not to take out this fold, but to produce another inner fold of the same depth. The point being returned back again in the same manner, produces a third fold; and thus the workman proceeds, until the whole has acquired the appearance of a flat circular piece, consisting of a number of concentric undulations or folds, with the point in the centre. This is laid upon the plank, where the workman, keeping the piece wet with the liquor, pulls out the point with his fingers, and presses it down with his hand, at the same time turning it round on its centre in contact with the plank, till he has, by this means, rubbed out a flat portion, equal to the intended crown of the hat. In the next place he takes a block, to the crown of which he applies the flat central portion of the felt, and by forcing a string down the sides of the block, he causes the next part to assume the figure of the crown, which he continues to wet and work, until it has properly disposed itself round the block. The rim now appears like a flounced or puckered appendage round the edge of the crown; but the block being set upright on the plank, the requisite figure is soon given by working, rubbing and extending this part. Water only is used in this operation of fashioning or blocking; at the conclusion of which it is pressed out by the blunt edge of a copper implement for that purpose.

"Previous to the dyeing, the nap of the hat is raised or loosened out with a wire brush, or carding instrument. The fibres are too rotten after the dyeing to bear this operation. The dyeing materials are logwood, and a mixture of the sulphates of iron and of copper, known in the market by the names of green copperas and blue vitriol. As the time of Mr Collinson was limited, and my attention, says Mr Nicholson, was more particularly directed to the mechanical processes, I did not go into the dye-house; but I have no doubt that the hats are boiled with the logwood, and afterwards immersed in the saline solution. I particularly asked whether galls were used, and was answered in the negative.

"The dyed hats are, in the next place, taken to the stiffening shop. One workman, assisted by a boy, does this part of the business. He has two vessels, or boilers, the one containing the grounds of strong beer, which costs seven shillings per barrel, and the other vessel containing melted glue a little thinner than it is used by carpenters. Our author particularly asked, whether this last solution contained any other ingredient besides glue, and was assured that it did not. The beer grounds are applied in the inside of the crown to prevent the glue from coming through to the face, and also, as he supposes, to give the requisite firmness at a less expence than could be produced by glue alone. If the glue were to pass through the hat in different places, it might, he imagines, be more difficult to produce an even gloss upon the face in the subsequent finishing. The glue stiffening is applied after the beer-grounds are dried, and then only upon the lower face of the flap, and the inside of the crown. For this purpose, the hat is put into another hat, called a stiffening hat, the crown of which is notched, or slit open in various directions. These are then placed in a hole in a deal board, which supports the flap, and the glue is applied with a brush.

"The dry hat, after this operation, is very rigid, and its figure irregular. The last dressing is given by the application of moisture and heat, and the use of the brush, and a hot iron, somewhat in the shape of that used by tailors, but shorter and broader on the face. The hat being softened by exposure to steam, is drawn upon a block, to which it is securely applied by the former method of forcing a string down from the crown to the commencement of the rim. The judgment of the workman is employed in moistening, brushing, and ironing the hat, in order to give and preserve the proper figure. When the rim of the hat is not intended to be of an equal width throughout, it is cut by means of a wooden, or perhaps metallic pattern; but as no such hats are now in fashion, Mr Nicholson saw only the tool for cutting them round. The contrivance is very ingenious and simple. A number of notches are made in one edge of a flat piece of wood for the purpose of inserting the point of a knife, and from one side or edge of this piece of wood there proceeds a strait handle, which lies parallel to the notched side, forming an angle somewhat like that of a carpenter's square. When the legs of this angle are applied to the outside of the crown, and the board lies flat on the rim of the hat, the notched edge will lie nearly in the direction of the

Hat-making.

the radius, or line pointing to the centre of the hat. A knife being therefore inserted in one of the notches, it is easy to draw it round by leaning the tool against the crown, and it will cut the border very regular and true. This cut is made before the hat is quite finished, and is not carried entirely through; so that one of the last operations consists in tearing off the redundant part, which by that means leaves an edging of beaver round the external face of the flap. When the hat is completely finished, the crown is tied up in gauze paper, which is neatly ironed down. It is then ready for the subsequent operations of lining," &c.

Our author concludes his valuable memoir on the fabrication of hats, with some observations on the probable gain or loss of employing machinery in the manufacture. These observations, as they are stated in the original paper, we recommend to the serious attention of every judicious hat-maker, who carries on his business on a large scale; for he will find them not the reveries of a rash speculatist, but the cool reflections of a real philosopher, who is at the same time no stranger to the arts of life. They suggest the following subjects of enquiry; Whether carding, which is rapidly and mechanically done, be inferior to bowing, which does not promise much facility for mechanical operation? Whether a succession of bats or cardings might be thrown round a fluted cone, which rapidly revolving, in contact with three or more cylinders, might perform the hardening, and even the working, with much more precision and speed than they are now done by hand? Whether blocking or shaping be not an operation extremely well calculated for the operation of one or more machines? Whether loose weaving and subsequent felting might not produce a lighter, cheaper, and stronger article? And how far the mechanical felting, which is not confined merely to the hairs of animals, might be applied to this art?

Before we dismiss this subject, it may be worth while to state Mr Dunnage's method of making *water-proof hats*, in imitation of beaver, for which, in November 1794, he obtained a patent. It is as follows: Let a shag be woven, of such count in the reed, and cut over such sized wire, as will give the hats to be manufactured from it that degree of richness, or appearance of fur, which may be thought necessary. The materials of which this shag may be composed are various, and should be accommodated to different kinds of hats, according to the degree of beauty and durability to be given them, and the price at which they are designed to be sold; that is to say, silk, mohair, or any other hair that is capable of being spun into an end fine enough for the purpose, cotton, inkle, wool, or a mixture of any, or all the above materials, as may suit the different purposes of the manufacturer. Those answer best, (says our author), which are made with two poles, either of Bergam, Piedmont, or Organzine silk, rising alternately, in a reed of about nine hundred count to eighteen inches wide, with three shoots over each wire. This method of weaving distributes the silk (as it may be put single into the harness), and prevents any ribby appearance which it might have if the silk were passed double, and the whole of the pole cut over each wire. This may be made either on a two or four thread ground of hard silk, shot with fine cotton, which he thinks preferable for shoot, to silk, inkle, or any other material, as it forms both a close and fine texture. An inferior kind of hats may be made from any of the before mentioned materials, and with cheaper silk. This shag should be stretched on a frame, such as dyers use to rack cloth; then (having previously set the pile upright with a comb, to prevent its being injured or stuck together), go over the ground with thin size, laid on with a soft brush. For black, or dark colours, common size will do; with white, or any light colour, use isinglass, or a size made from white kid leather. These, or gum, or any other mucilaginous matter, which, without altering the colour, will prevent oil from getting through the ground so as to injure the pile, will answer the purpose. Take care not to apply more of any material, as a preparation, than may be fully saturated with oil or varnish, so that water will not discharge it from the ground. The size, or other glutinous matter, being dry, the pile must be teaseled, or carded with a fine card, till the silk is completely taken out of the twist or throwing, when it will lose its coarse shaggy look, and assume the appearance of a very fine fur. It must now be once more set upright with a comb, and you may proceed to lay on your water-proof material; this too may be varied according to circumstances. For black, or any dark colour, linseed oil well boiled with the usual driers, and thickened with a small quantity of any good drying colour, will do; for white, or very fine colours, poppy or nut oil, or copal or other varnishes, may be used. In this particular the manufacturer must judge what will best answer his purpose, taking care never to use any thing that will dry hard, or be subject to crack. Mr Dunnage has found good drying linseed oil preferable to any other thing which he has used, and, with the precaution of laying on very little the first time, it will not injure the finest colours. When the first coat of oil is dry, go over it a second and a third time, if necessary, till you are convinced the pores of the ground are fully closed up, and the stuff rendered impervious to water. It should now stand several days, till the smell is sufficiently gone off; and before it is taken from the frame, should be gone over with some ox gall or lime-water, to take off the greasiness, which would otherwise prevent the stiffening from adhering to the oil. The material being now ready to be formed into hats, should be cut into proper shapes for that purpose. The crown should be made up over a block, with needle and silk, the oiled side outwards. The seams should then be rubbed with a piece of hard wood, bone, or ivory, to make them lie flat, and the edges of the stuff pared off very near the stitches, that no joint may appear on the right side. The seams should then be carefully gone over with the prepared oil, till every crevice or hole made by the needle is completely filled up, and the crown rendered perfectly water-proof. The crown may then be turned and stiffened, by sticking linen, leather, paper, or any other material that may be found to answer the purpose, to the inner or painted side, till it acquires about the same degree of stiffness, or resistance to the touch, as a good beaver. The mucilaginous matter which he used to attach the stiffening to the crown, and the upper and under parts of the brim to each other, was composed of one pound of gum arabic or senega, one pound of starch, and a half a pound of glue, boiled up with as much water as reduced the whole to the consistence of a thick paste. A greater or less proportion of any of these ingredients may be used, and other glutinous and adhesive substances may answer the same purposes; or drying-oils may be made use of, instead of this or other mucilage; or any of the resinous gums dissolved in oil or spirits; only it should be observed, in this case, the hats will require more time in the preparation, as the oily matter, unless exposed to the air, will not readily dry; but he found by experience that the above mentioned composition does not dry hard or brittle, but retains that pleasant flexibility which is agreeable to the touch, while it communicates to the other materials a sufficient degree of elasticity. Before the brim is perfectly dry, care should be taken to form a neck or rising round the hole where it is to be attached to the crown, by notching it round with a pair of scissars, and then forcing it over a block something larger than you have made the hole, so that the uncut stuff may turn up, under the lower edge of the crown, about a quarter of an inch. Before you join the crown and brim together, go over the outside of the neck of the brim, and the inside of the crown, as high as the neck will come (which should be about half an inch), with the prepared oil; and when they are nearly dry, so as to adhere to the finger on touching them, put the crown over the neck of the brim, and let them be sewed strongly together, taking care to sew down as little of the pile as possible, and using the same precaution of oiling, where the needle has been through, as was observed in making up the crown. The hat is now ready for dressing; which operation may be performed over a block, with a hot iron, brush, &c. in the same manner as those commonly called felts. When putting in the lining, be very careful to let the needle only take hold of the under surface of the brim; for should it perforate the upper one, the water will find its way through, and the hat be of no value. Though we have already declared how little we are acquainted with the operation of hat-making, we cannot help suggesting the enquiry, whether these water-proof hats might not be improved both in strength and beauty, by a slight felting before the application of the size by the brush. Such of them as are composed of wool or hair, or contain a mixture of these materials, are unquestionably susceptible of felting.

HATBOROUGH, a small town in Montgomery county, Pennsylvania, situated on the N. E. side of Pennepeck Creek, which runs into Delaware river about 5 miles above Frankfort. It contains about 20 houses.—*Morse.*

HATCHY, a navigable river in the State of Tennessee, runs westerly into the Mississippi, about 19 miles N. of Wolf river, and is about 80 yards wide 7 miles from its month.—*ib.*

HATFIELD, a very pleasant town in Hampshire county, Massachusetts, situated on the west bank of a bend of Connecticut river where it is 80 rods wide, 5 miles north of Northampton, and 100 west of Boston. It lies chiefly on one street, and contains 103 houses, and 703 inhabitants. Here are two ferries on Connecticut river; the one to Hadley, the other to Amherst. North of the ferry to Amherst, the river meets with a bed of rocks, which lessens its breadth 20 or 30 rods—no fall, but a large eddy at high water.—*ib.*

HATTERAS is the most remarkable and dangerous cape on the coast of N. America. This point extends far into the ocean, from the coast of N. Carolina, in 35° 15′ N. lat. The water is very shoal at a great distance from the cape, which is remarkable for sudden squalls of wind, and for the most severe storms of thunder, lightning and rain, which happen almost every day, during one half the year. At the time of Sir Walter Raleigh's approaching this coast, the shoals in the vicinity of Hatteras were found so dangerous, so extensive, and so shallow, many of them covered with not more than 5 or 6 feet water, that no vessels, in that latitude, ventured within 7 leagues of the land.

At present the out-shoals, which lie about 14 miles S. W. of the cape, are but of 5 or 6 acres extent, and where they are really dangerous to vessels of moderate draught, not above half that extent. On the shoalest part of these is about 10 feet at low water; and here, at times, the ocean breaks in a tremendous manner, spouting, as it were, to the clouds, from the violent agitation of the Gulf Stream, which touches the eastern edge of the banks, from which the declivity is sudden, that is to say, from 10 fathoms to no soundings. On the spot above mentioned, which is firm sand, it has been the lot of many a good vessel to strike, in a gale of wind, and go to pieces. In moderate weather, however, these shoals may be passed over, if necessary, at full tide, without much danger, by vessels not drawing more than 8, 9, or 10 feet water. From this bank, formerly of vast extent, and called the *Full Moon Shoal*, a ridge runs the whole distance to the cape about a N. W. course, is about half a mile wide, and at low water has generally, 10, 11 and 12 feet water. There are gaps at equal intervals, affording channels of about 15 or 16 feet water. The most noted of these is about a mile and a half from the land, and is at least two miles and a half wide, and might at full sea be safely passed by the largest ships; but is rarely used except by coasting vessels. It may be easily known by a range of breakers always seen on the west side, and a breaker head or two on the eastern side; which, however, are not so constant, only appearing when the sea is considerably agitated. A little north of the cape is good anchoring in 4 or 5 fathoms; and with the wind to the westward, a boat may land in safety, and even bring off casks of fresh water, plenty of which is to be found every where on the beach, by digging a foot or two, and putting a barrel into the sand.—*ib.*

HATTON'S FORD, on Tugelo river, a village 16 miles from Pendleton court-house, in S. Carolina, and 17 from Franklin court-house, in Georgia.—*ib.*

HAVERFORD, a township in Delaware county, Pennsylvania.—*ib.*

HAVERHILL, a post-town of New-Hampshire, and the capital of Grafton county, situated on the east side of Connecticut river, in Lower Coos. It has between 40 and 50 compact houses, a well constructed court-house, and a congregational church. This township was incorporated in 1763, and contains 552 inhabitants. In it is a bed of iron ore, which has yielded some profit to the proprietor, also a quarry of freestone, fit for hearths and chimney pieces. It has also a fulling-mill, an oil-mill, and many other excellent mill seats. It is opposite to Newbury in Vermont, 35 miles

miles above Dartmouth college, 119 miles N. W. of Portsmouth.—*ib.*

HAVERHILL, a handsome post-town of Massachusetts, in Essex county, situated on the N. side of Merrimack river, across which is an elegant bridge, connecting this town with Bradford, 650 feet long and 34 wide. It has 3 arches, of 180 feet each, supported by 3 handsome stone piers, 40 feet square; also a draw of 30 feet, over the channel of the river. Haverhill has a considerable inland trade, lying about 32 miles N. by W. of Boston, and 12 miles from Newburyport, at the mouth of the river, and about 28 S. W. of Portsmouth in New-Hampshire. It lies chiefly upon two streets; the principal of which runs parallel with the river. Vessels of 100 tons burden can go up to it. Travellers are struck with the pleasantness of the situation; and a number of neat and well finished houses give it an air of elegance. Here are two churches, one for Congregationalists and one for Baptists; 3 distilleries, one of which has lately undergone a laudable transmutation into a brewery. Some vessels are annually built here, and several are employed in the West India trade. A manufactory of sail-cloth was begun here in 1789, and is said to be in a promising way. The trade of the place, however, is considerably less than before the revolution. The whole township contains 330 houses, and 2,408 inhabitants. —*ib.*

HAVERSTRAW BAY, called by some *Haversham*, in Hudson's river, 38 miles above New-York city, spreads S. of Stony Point, and before the town of its own name, is 10 miles long and about 3 wide. —*ib.*

HAVERSTRAW, a township in Orange county, New-York, situated on the W. side of the above bay, 35 miles N. of New-York city. It contains 4,826 inhabitants, of whom 98 are qualified electors, and 238 slaves.—*ib.*

HAVRE DE GRACE, or GRAS, a post-town and port of entry in Harford county, Maryland, on the W. side of Susquehannah river, at its mouth in Chesapeak Bay. It contains about 40 houses, 250 inhabitants, and is the port of entry for all the shores of Chesapeak Bay above Turkey Point. It is 6 miles W. by S. of Charleston in Cecil county, 37 N. E. of Baltimore, and 65 W. S. W. of Philadelphia. N. lat. 39° 39′.—*ib.*

HAW, a water of Cape Fear which unites with Deep river. It may be rendered navigable for 50 miles.—*ib.*

HAWKE, a township in Rockingham county, New-Hampshire, was incorporated in 1760, and contained in 1775, 504, and in 1790, 420 inhabitants.—*ib.*

HAWKINS (Sir John), was the youngest son of a man who, though descended from Sir John Hawkins the memorable admiral and treasurer of the navy in the reign of Queen Elizabeth, followed at first the occupation of a house-carpenter, which he afterwards exchanged for the profession of a surveyor and builder. He was born in the city of London on the 30th day of March 1719; and after having been sent first to one school, and afterwards to a second, where he acquired a tolerable knowledge of Latin, he went through a regular course of architecture and perspective, in order to fit him for his father's profession of a surveyor. He was, however, persuaded, by a near relation, to abandon the profession of his first choice, and to embrace that of the law; and was accordingly articled to Mr John Scott an attorney and solicitor in great practice. In this situation his time was too fully employed in the actual dispatch of business to permit him, without some extraordinary means, to acquire the necessary knowledge of his profession by reading and study; besides that, his master is said to have been more anxious to render him a good copying clerk, by scrupulous attention to his hand-writing, than to qualify him by instruction to conduct business. To remedy this inconvenience, therefore, he abridged himself of his rest, and rising at four in the morning, found opportunity of reading all the necessary and most eminent law writers, and the works of our most celebrated authors on the subjects of verse and prose. By these means, before the expiration of his clerkship, he had rendered himself a very able lawyer, and had acquired a love for literature in general, but particularly for poetry and the polite arts; and the better to facilitate his improvement, he occasionally furnished to the Universal Spectator, the Westminster Journal, the Gentleman's Magazine, and other periodical publications of the time, essays and disquisitions on several subjects. The first of these is believed to have been an Essay on *Swearing*; but the exact time of its appearance, and the paper in which it was inserted, are both unknown. It was, however, re-published some years before his death (without his knowledge till he saw it in print) in one of the newspapers. His next production was an Essay on *Honesty*, inserted in the Gentleman's Magazine for March 1739; and which occasioned a controversy, continued through the Magazines for several succeeding months, between him and a Mr Calamy, a descendant of the celebrated Dr Edmund Calamy, then a fellow-clerk with him.

About the year 1741, a club having been instituted by several amateurs of music, under the name of the Madrigal Society, to meet every Wednesday evening, and his clerkship being now out, he became a member of it, and continued so many years. Pursuing his inclination for music still farther, he became also a member of the Academy of Ancient Music, which used to meet every Thursday evening at the Crown and Anchor in the Strand, but since removed to Freemasons Hall; and of this he continued a member till a few years before its removal.

Impelled by his own taste for poetry, and excited to it by his friend Foster Webb's example, who had contributed to the Gentleman's Magazine many very elegant poetical compositions, he had, before this time, himself become an occasional contributor in the same kind, as well to that as to some other publications. The earliest of his productions of this species, now known, is supposed to be a copy of verses "To Mr George Stanley, occasioned by looking over some Compositions of his lately published," which bears date 19th February 1740, and was inserted in the Daily Advertiser for February 21. 1741; but, about the year 1742, he proposed to Mr Stanley, the project of publishing, in conjunction with him, six cantatas for a voice and instruments, the words to be furnished by himself, and the music by Mr Stanley. The proposal was accepted, the publication was to be at their joint expence, and for their mutual benefit; and accordingly, in 1742, six cantatas were thus published, the five first written by Mr Hawkins, the sixth and last by Foster Webb; and these having succeeded

Hawkins.

ceeded beyond the most sanguine expectations of their authors, a second set of six more, written wholly by himself, was in like manner published a few months after, and succeeded equally well.

As these compositions, by being frequently performed at Vauxhall, Ranelagh, and other public places, and at many private concerts, had become favourite entertainments, many persons, finding the author also a modest well-informed young man of unexceptionable morals, were become desirous of his acquaintance. Among these was Mr Hare of Limehouse, a brewer, who being himself a musical man, and having met him at Mr Stanley's at musical parties, gave him an invitation to his house: and, to forward him in his profession, introduced him to a friend of his, Peter Storer of Highgate, Esq; which proved the means of making his fortune.

In the winter of the year 1749, Dr then Mr Johnson, was induced to institute a club to meet every Tuesday evening at the King's Head, in Ivy-lane, near St Paul's. It consisted only of nine persons; and Mr Hawkins was one of the first members. About this time, as it is supposed, finding his father's house, where he had hitherto resided, too small for the dispatch of his business, now very much increasing, he, in conjunction with Dr Munckley, a physician, with whom he had contracted an intimacy, took a house in Clements-lane, Lombard-street. The ground floor was occupied by him as an office, and the first floor by the Doctor as his apartment. Here he continued till the beginning of 1753, when, on occasion of his marriage with Sidney, the youngest of Mr Storer's daughters, who brought him a considerable fortune, he took a house in Austin Friars, near Broad-street, still continuing to follow his profession of an attorney.

Having received, on the death of Peter Storer, Esq; his wife's brother, in 1759, a very large addition to her fortune, he quitted business to Mr Clark, afterwards Alderman Clark, who had a short time before completed his clerkship under him, disposed of his house in Austin Friars, and purchased a house at Twickenham. Soon afterwards he bought the lease of one in Hatton-street London, for a town residence.

From a very early period of his life he had entertained a strong love for the amusement of angling; and his affection for it, together with the vicinity of the river Thames, was undoubtedly his motive to a residence at this village. He had been long acquainted with Walton's Complete Angler; and had, by observation and experience, become himself a very able proficient in the art. Hearing, about this time, that Mr Moses Browne proposed to publish a new edition of that work, and being himself in possession of some material particulars respecting Walton, he, by letter, made Mr Browne an offer of writing, for his intended edition, Walton's Life. To this proposal no answer was returned, at least for some time; from which circumstance Mr Hawkins concluded, as any one reasonably would, that his offer was not accepted; and, therefore, having also learnt that Mr Browne meant not to publish the text as the author left it, but to modernize it, in order to file off the rust, as he called it, he wrote again to tell Mr Browne that he understood his intention was to sophisticate the text, and that therefore he, Mr Hawkins, would himself publish a correct edition. Such an edition, in 1760, he accordingly published in octavo with notes, adding to it a Life of Walton by himself, a Life of Cotton, the author of the second part by the well-known Mr Oldys; and a set of cuts designed by Wale, and engraved by Ryland.

Hawkins.

His propensity to music, manifested by his becoming a member and frequenter of the several musical societies before mentioned, and also by a regular concert at his house in Austin Friars, had led him, at the time that he was endeavouring to get together a good library of books, to be particularly solicitous for collecting the works of some of the best musical composers; and, among other acquisitions, it was his singular good fortune to become possessed by purchase of several of the most scarce and valuable theoretical treatises on the science any where extant, which had formerly been collected by Dr Pepusch. With this stock of erudition, therefore, he, about this time, at the instance of some friends, set about procuring materials for a work then very much wanted, a History of the Science and Practice of Music, which he afterwards published.

At the recommendation of the well known Paul Whitehead, to the Duke of Newcastle, then Lord Lieutenant for Middlesex, his name was, in 1761, inserted in the Commission of the Peace for that county; and having by the proper studies, and a sedulous attendance at the sessions, qualified himself for the office, he became an active and useful magistrate in the county (A). Observing, as he had frequent occasion to do in the course of his duty, the bad state of highways, and the great defect in the laws for amending and keeping them in repair, he set himself to revise the former statutes, and drew an act of parliament consolidating all the former ones, and adding such other regulations as were necessary. His sentiments on this subject he published in octavo, in 1763, under the title of "Observations on the State of Highways, and on the Laws for amending and keeping them in repair;" subjoining to them the draught of the act before mentioned; which bill being afterwards introduced into parliament, passed into a law, and is that under which all the highways in England are at this time kept repaired. Of this bill it is but justice to add, that, in the experience of more than thirty years, it has never required a single amendment.

Johnson and Sir Joshua, then Mr Reynolds, had, in the winter of this year 1763, projected the establishment of a club to meet every Monday evening at the Turk's Head in Gerard street; and, at Johnson's solicitation, Mr Hawkins became one of the first members.

An

(A) When he first began to act, he formed a resolution of taking no fees, not even the legal and authorised ones, and pursued this method for some time, till he found that it was a temptation to litigation, and that every trifling ale-house quarrel produced an application for a warrant. To check this, therefore, he altered his mode, and received his due fees, but kept them separately in a purse; and at the end of every summer, before he left the country for the winter, delivered the whole amount to the clergyman of the parish, to be by him distributed among such of the poor as he judged fit.

An event of confiderable importance engaged him, in the year 1764, to ftand forth as the champion of the county of Middlefex, againft a claim then for the firft time fet up, and fo enormous in its amount as juftly to excite refiftance. The city of London finding it neceffary to re-build the gaol of Newgate, the expence of which, according to their own eftimates, would amount to L.40,000, had this year applied to parliament, by a bill brought into the Houfe of Commons, in which, on a fuggeftion that the county prifoners removed to Newgate for a few days previous to their trials at the Old Bailey, were as two to one of the London prifoners, conftantly confined there, they endeavoured to throw the burthen of two-thirds of the expence on the county, while they themfelves propofed to contribute one-third only. This attempt the magiftrates for Middlefex thought it their duty to oppofe; and accordingly a vigorous oppofition to it was commenced and fupported under the conduct of Mr Hawkins, who drew a petition againft the bill, and a cafe of the county, which was printed and diftributed amongft the members of both houfes of parliament. It was the fubject of a day's converfation in the Houfe of Lords; and it produced fuch an effect in the Houfe of Commons, that the city, by its own members, moved for leave to withdraw the bill. The fuccefs of this oppofition, and the abilities and fpirit with which it was conducted, naturally attracted towards Mr Hawkins the attention of his fellow-magiftrates; and the chairman of the quarter feffions dying not long after, he was, on the 19th day of September 1765, elected his fucceffor.

In the year 1771, he quitted Twickenham, and fold his houfe there to Mr Vaillant; and, in the fummer of the next year, for the purpofe of obtaining, by fearches in the Bodleian and other libraries, farther materials for his hiftory of mufic, he made a journey to Oxford, carrying with him an engraver from London, to make drawings from the portraits in the mufic fchool.

On occafion of actual tumults or expected difturbances, he had more than once been called into fervice of great perfonal danger. When the riots at Brentford had arifen, during the time of the Middlefex election in the year 1768, he and fome of his brethren attended to fupprefs them; and, in confequence of an expected riotous affembly of the journeymen Spital-fields weavers in Moorfields in 1769, the magiftrates of Middlefex, and he at their head, with a party of guards, attended to oppofe them; but the mob, on feeing them prepared, thought it prudent to difperfe. In thefe and other inftances, and particularly in his conduct as chairman, having given fufficient proof of his activity, refolution, abilities, integrity and loyalty, he, on the 23d of October 1772, received from his majefty the honour of knighthood.

In 1773 Dr Johnfon and Mr Stevens publifhed, in ten volumes octavo, their firft joint edition of Shakefpeare, to which Sir John Hawkins contributed fuch notes as are diftinguifhed by his name, as he afterwards did a few more on the republication of it in 1778. An addrefs to the king from the county of Middlefex, on occafion of the American war, having, in 1774, been judged expedient, and at his inftance voted, he drew up fuch an addrefs, and, together with two of his brethren, had, in the month of October in that year, the honour of prefenting it.

After fixteen years labour, he, in 1776, publifhed, in five volumes quarto, his General Hiftory of the Science and Practice of Mufic; which in confequence of permiffion obtained in 1773, he dedicated to the king, and prefented it to him at Buckingham-houfe on the 14th of November, 1776, when he was honoured with an audience of confiderable length both from the king and queen.

Not long after this publication, that is to fay in November 1777, he was induced, by an attempt to rob his houfe, which, though unfuccefsful, was made three different nights with the interval of one or two only between each attempt, to quit his houfe in Hatton-ftreet; and, after a temporary refidence for a fhort time in St James's Place, he took a leafe of one, formerly inhabited by the famous admiral Vernon, in the ftreet leading up to Queen Square, Weftminfter, and removed thither.

By this removal he became a conftant attendant on Divine worfhip at the parifh-church of St Margaret, Weftminfter; and having learnt, in December 1778, that the furveyor to the board of ordnance was, in defiance of a provifo in the leafe under which they claimed, carrying up a building at the eaft end of the church, which was likely to obfcure the beautiful painted glafs window over the altar there, Sir John Hawkins, with the concurrence of fome of the principal inhabitants, wrote to the furveyor, and compelled him to take down two feet of the wall, which he had already carried up above the fill of the window, and to flope off the roof of his building in fuch a manner as that it is not only no injury, but, on the contrary, a defence to the window.

In the month of December 1783, Dr Johnfon having difcovered in himfelf fymptoms of a dropfy, fent for Sir John Hawkins, and telling him the precarious ftate of his health, declared his defire of making a will, and requefted him to be one of his executors. Sir John accepted the office; inftructed the Doctor how to make his will: and on his death undertook to be his biographer, and the guardian of his fame, by publifhing a complete edition of his works.

Not three months after the commencement of this undertaking, he met with the feverett lofs of almoft any that a literary man can fuftain, fhort of that of his friends or relations, in the deftruction, by fire, of his library; confifting of a numerous and well chofen collection of books, ancient and modern, in many languages, and on moft fubjects, which it had been the bufinefs of above 30 years at intervals to get together. Of this lofs, great as it was in pecuniary value, and comprifing in books, prints, and drawings, many articles that could never be replaced, he was never heard in the fmalleft degree to complain; but having found a temporary reception in a large houfe in Orchard-ftreet, Weftminfter, he continued there a fhort time, and then took a houfe in the Broad Sanctuary, Weftminfter.

This event, for a fhort time, put a ftop to the progrefs of his literary purfuits. As foon, however, as he could fufficiently collect his thoughts, he recommenced his office of biographer of Johnfon; and completed his intention by publifhing, in 1787, the life and works, in eleven volumes octavo, which he dedicated to the king.

With this production he terminated his literary labours; and having for many years been more particularly fedulous in his attention to the duties of religion, and accuſtomed to ſpend all his leiſure from other neceſſary concerns in theological and devotional ſtudies, he now more cloſely addicted himſelf to them, and ſet himſelf to prepare for that event, which he ſaw could be at no great diſtance; and the better to accompliſh this end, in the month of May 1788, he, by a will and other proper inſtruments, made ſuch an arrangement of his affairs as he meant ſhould take place after his deceaſe.

In this manner he ſpent his time till about the beginning of May 1789, when, finding his appetite fail him in a greater degree than uſual, he had recourſe, as he had ſometimes had before on the ſame occaſion, to the waters of the Iſlington Spa. Theſe he drank for a few mornings; but on the 14th of that month, while he was there, he was, it is ſuppoſed, ſeized with a paralytic affection, as, on his returning to the carriage which waited for him, his ſervants perceived a viſible alteration in his face. On his arrival at home, he went to bed, but got up a few hours after, intending to receive an old friend, from whom he expected a viſit in the evening. At dinner, however, his diſorder returning, he was led up to bed, from which he never roſe, on the 21ſt of the ſame month, about two in the morning, dying of an apoplexy. He was interred on the 28th in the cloiſters of Weſtminſter Abbey, in the north walk near the eaſtern door into the church, under a ſtone, containing, by his expreſs injunctions, no more than the initials of his name, the date of his death, and his age; leaving behind him a high reputation for abilities and integrity, united with the well-earnt character of an active and reſolute magiſtrate, an affectionate huſband and father, a firm and zealous friend, a loyal ſubject, and a ſincere Chriſtian.

Such is the character of him in the Biographical Dictionary, which we have neither right nor inclination to controvert. With none of his works are we acquainted but his edition of *Walton's Complete Angler*, and his *Life of Johnſon*. The former is a very pleaſing book; and in the latter are collected many intereſting anecdotes of literature and literary men; but they are not well arranged, and the ſtyle of the compoſition is coarſe and ſlovenly. Sir John, we doubt not, was a man of worth, and his reflections on the ſentimental ſlang of Sterne and others, ſhew that he had ſucceſsfully ſtudied human nature; but he certainly was not a man of general taſte.

HAWKINS, a county in Waſhington diſtrict, in Tenneſſee, having 6,970 inhabitants, incluſive of 807 ſlaves. Chief town, Rogerſville.—*Morſe.*

HAWKINS *Court-Houſe*, in Tenneſſee, is 25 miles from Free-ſtone Gap, 72 from Abington, and 178 from Danville in Kentucky.—*ib.*

HAWK'S BAY, on the coaſt of Weſt-Florida, weſtward of the mouth of Mobile Bay, is between Pelican and Dauphin iſlands. There is a broad channel of 11 and 12 feet water, afterwards ſafe anchorage in 4 fathoms, good holding ground, and ſheltered from moſt winds; on which account it is very convenient for ſmall veſſels.—*ib.*

HAWK'S HARBOUR is an arm of Igornachoix Bay, Newfoundland Iſland.—*ib.*

HAWLEY, a townſhip in Hampſhire county, Maſſachuſetts, 120 miles weſterly of Boſton. Previous to its incorporation in 1792, it was called *Plantation No.* 7, and had 539 inhabitants. It is compoſed of parts of ſeveral adjoining towns, and is about 20 miles N. W. of Northampton.—*ib.*

HAYCOCKS, a ſmall iſle in Delaware river, about 7 miles below Eaſton, in Northampton county, Pennſylvania.—*ib.*

HAYNE'S FORT, COLONEL, is ſituated in Nelſon county, Kentucky, on the north ſide of Green river, 25 miles weſt of Craig's Fort, and 53 from the Ohio.—*ib.*

HEAT. See in this Supplement, CHEMISTRY, Part I. chap. v. where we have endeavoured to eſtabliſh the modern doctrine reſpecting *Caloric* or latent heat. In nº 309, &c. of that article, we have given an account of Count Rumford's ingenious experiments, inſtituted with a view to determine whether or not caloric be a ſubſtance, and have ſtated our reaſons for diſſenting from his opinion. It has been ſuggeſted to us, however, by a friend, to whoſe judgment we are inclined to pay great deference, that it would be proper, in this place, to give the Count's arguments at full length, and in his own words: and the propriety of this is the more apparent, that in the ſupplementary article ELECTRICITY, we have hinted our own ſuſpicions of the non-exiſtence of an *electrical fluid*. The Count then reaſons from his experiments in the following words:

"By meditating on the reſults of all theſe experiments, we are naturally brought to that great queſtion which has ſo often been the ſubject of ſpeculation among philoſophers, namely, What is heat?—Is there any ſuch thing as an *igneous fluid?*—Is there any thing that can with propriety be called caloric?

"We have ſeen that a very conſiderable quantity of heat may be excited in the friction of two metallic ſurfaces, and given off in a conſtant ſtream or flux *in all directions*, without interruption or intermiſſion, and without any ſigns of diminution or exhauſtion.

"From whence came the heat which was continually given off in this manner in the foregoing experiments? Was it furniſhed by the ſmall particles of metal detached from the larger ſolid maſſes on their being rubbed together? This, as we have already ſeen, could not poſſibly have been the caſe.

"Was it furniſhed by the air? This could not have been the caſe; for in three of theſe experiments, the machinery being kept immerſed in water, the acceſs of the air of the atmoſphere was completely prevented.

"Was it furniſhed by the water which ſurrounded the machinery? That this could not have been the caſe is evident; *firſt*, becauſe this water was continually *receiving heat* from the machinery, and could not at the ſame time be *giving to* and *receiving heat from* the ſame body; and, *ſecondly*, becauſe there was no chemical decompoſition of any part of this water. Had any ſuch decompoſition taken place (which indeed could not reaſonably have been expected), one of its compound elaſtic fluids (moſt probably inflammable air) muſt at the ſame time have been ſet at liberty, and, in making its eſcape into the atmoſphere, would have been detected; but though I frequently examined the water to ſee if any air bubbles roſe up through it, and had even made preparations for catching them in order to examine them if any ſhould appear, I could perceive none;

nor

nor was there any ſign of decompoſition of any kind whatever, or other chemical proceſs going on in the water.

"Is it poſſible the heat could have been ſupplied by means of the iron bar to the end of which the blunt ſteel borer was fixed? or by the ſmall neck of gun-metal by which the hollow cylinder was united to the cannon? Theſe ſuppoſitions appear more improbable even than either of thoſe before mentioned; for heat was continually going off or *out of the machinery*, by both theſe laſt paſſages, during the whole time the experiment laſted.

"And, in reaſoning on this ſubject, we muſt not forget to conſider that moſt remarkable circumſtance, that the ſource of the heat generated by friction in theſe experiments appeared evidently to be inexhauſtible.

"It is hardly neceſſary to add, that any thing which any *inſulated* body or ſyſtem of bodies can continue to furniſh *without limitation*, cannot poſſibly be a *material ſubſtance*; and it appears to me to be extremely difficult, if not quite impoſſible, to form any diſtinct idea of any thing capable of being excited and communicated in the manner the heat was excited and communicated in theſe experiments, except it be motion.

"But although the mechaniſm of heat ſhould in fact be one of theſe myſteries of nature which are beyond the reach of human intelligence, this ought by no means to diſcourage us, or even leſſen our ardour, in our attempts to inveſtigate the laws of its operations. How far can we advance in any of the paths which ſcience has opened to us, before we find ourſelves enveloped in thoſe thick miſts which on every ſide bound the horizon of the human intellect? But how ample and intereſting is the field that is given us to explore?

"Nobody, ſurely, in his ſober ſenſes has ever pretended to underſtand the mechaniſm of gravitation; and yet what ſublime diſcoveries was our immortal Newton enabled to make, merely by the inveſtigation of the laws of its action! The effects produced in the world by the agency of heat are probably *juſt as extenſive* and quite as important, as thoſe which are owing to the tendency of the particles of matter towards each other; and there is no doubt but its operations are in all caſes determined by laws equally immutable."

HEATH, a townſhip in Hampſhire county, Maſſachuſetts, containing 379 inhabitants. It was incorporated in 1785, and is 125 miles N. W. of Boſton, and about 18 miles N. N. W. of Northampton.—*Morse.*

HEBRON, a town in Cumberland county, Maine, ſituated on the N. E. ſide of Little Androſcoggin, was incorporated in 1792. It is 35 miles N. by W. of Portland.—*ib.*

Hebron, a townſhip in Waſhington county, New-York, containing 1703 inhabitants, of whom 414 are electors.—*ib.*

Hebron, a townſhip in Tolland county, Connecticut, ſettled in 1704 from Northampton. Moſt of the lands were given by Joſhua, ſachem of the Mohegan tribe, in his laſt will and teſtament. It lies between Lebanon and Glaſtenbury, about 18 miles S. E. of Hartford, and 16 ſouth of Tolland.—*ib.*

Hebron, a Moravian ſettlement in Pennſylvania, 16 miles from Litiz, which is 70 miles northerly of Philadelphia. This ſettlement began in 1757.—*ib.*

HECTOR, a military townſhip in the State of New York, on the eaſt ſide of Seneca Lake toward the ſouth end, having Ovid on the north and Newtown townſhip on the ſouth, and 29 miles S. by W. of the ferry on Cayuga Lake.—*ib.*

HEIDELBERG, a Moravian ſettlement in Pennſylvania, begun in 1743; ſituated 24 miles from Litiz, which is in Warwick townſhip, Lancaſter county.—*ib.*

Heidelberg, a handſome town in Dauphine county, Pennſylvania, containing about 100 houſes and two German churches for Lutherans and Calviniſts; one of the churches is a handſome ſtone building. It is 33 miles E. by N. of Harriſburg, and 74 N. W. by W. of Philadelphia. There are two other townſhips of this name in the State, the one in York county, the other in that of Northampton.—*ib.*

HEIGHT OF LAND, a range of mountains which extend from S. W. to the N. E. and ſeparates the Diſtrict of Maine from Lower Canada, giving riſe to many rivers which fall into St Lawrence river, and others which fall into the Atlantic Ocean. The principal growth between the Height of Land and St Francis river is beech, maple, birch, hemlock and fir, very few white pines, and no oak of any ſort. Some of the rivers have fine intervales.—*ib.*

HELENA, or St Helena. In addition to the account of this iſland in the *Encyclopædia*, the following particulars from Sir George Staunton deſerve a place in this *Supplement*, becauſe ſome of them are important in themſelves, while others correct one or two miſtakes into which we had fallen, by adopting, implicitly, the narrative of Forſter.

The circumference of St Helena meaſures ſomewhat leſs than twenty-eight miles. Along the whole coaſt to leeward, or to the northward, ſhips may anchor in perfect ſecurity in all ſeaſons of the year, but the bank ſhelves ſo abruptly afterwards, that the anchorage, being in deep water, is inſecure. The tide ſeldom riſes above three feet and a half; but the ſurge of the ſea is ſometimes tremendous; and ſeveral accidents happened in approaching or quitting the ſhore, until a wharf was erected, lately, which renders the arrival there, and departure from it, perfectly ſafe. In the immediate neighbourhood of the iſland, ſtorms are little known, thunder is rarely heard, and lightning is ſeldom perceived.

The ſteep eminences which intervene between the valleys, that are the chief ſeats of population, render the communication from one part of this little ſpot to another ſlow and difficult. Planters on the windward ſide of the iſland conſider a journey to the leeward, or ſeat of government, as a ſerious undertaking. Several of them take that opportunity of paying their reſpects to the governor, which is called there ſometimes "going to court." There are St Helena planters who have not travelled ſo far. At preſent, by order of the governor, there are ſignals ſo placed all round the iſland, as to give inſtant notice of the approach of veſſels to any part of it.

In the *Encyclopædia*, it is ſaid that peaches are the only European fruits which thrive in St Helena; but this appears to be a miſtake. Several ſorts of fruit trees imported into the iſland had been deſtroyed by a particular inſect; but encouragement has been given for the cultivation of thoſe which that miſchievous animal is known to ſpare, ſuch as the apple, for example,

 with

with all the varieties of which it is susceptible. The plantain and banana, or the two species of the *musa*, thrive also remarkably well. The ground is fertile, and in favourable seasons produces, in some instances, double crops within the year. Plantations, however, of cotton, indigo, or canes, were not found to answer: though some good coffee has been produced in it. A botanic garden has been established near the governor's country house. An intelligent gardener has been sent to take care of it by the company; and a vast variety of trees, plants, and flowers of different, and sometimes opposite climates, are already collected in it. The surrounding sea abounds in esculent fish; and seventy different species, including turtle, have been caught upon the coasts. Whales are seen in great numbers playing round the island, where it is supposed the southern whale fishery might be carried on to great national advantage.

The country is chiefly cultivated by blacks. Persons of that colour were brought in a state of slavery to it by its first European settlers; and it seldom happens that white men will submit to common work where there are black slaves to whom it may be transferred. These were for a long time under the unlimited dominion of their owners, until a representation of the abuses made of that power induced the India Company to place them under the immediate protection of the magistracy, and to enact various regulations in their favour; which have contributed to render them, in a great degree, comfortable and secure. These regulations may have hurt, at first, the feelings of the owners of slaves, but not their real interest; for it appears, that before their introduction there was a loss, upon an average, of about ten in a hundred slaves every year, to be supplied at a very heavy expence; whereas, under the present system, they naturally increase. All future importation of slaves into the island is prohibited.

Besides the blacks in a state of slavery, there are some who are free. The labour of these tending to diminish the value of that of slaves, the free blacks became once obnoxious to some slave owners; who had sufficient influence, in a grand jury, to present them as without visible means of gaining a livelihood, and liable to become burdensome to the community; but upon examination, it appeared that all free blacks of age to work were actually employed; that not one of them had been tried for a crime for several years, nor had any of them been upon the parish. They are now by the humane interposition of the company placed under the immediate protection of the government, and put nearly upon a footing with the other free inhabitants, who, when accused of crimes, have the privilege of a jury, as well as in civil causes.

The principal settlement of St Helena has the peculiar advantage of uniting the shelter of a leeward situation with the coolness of windward gales. The south-east wind blows constantly down the valley, rendering a residence in it pleasant as well as healthy. The country is so fertile, and the climate so congenial to the human feelings, that perhaps it would be difficult to find out a spot where persons, not having acquired a relish for the enjoyments of the world, or already advanced in life, and surfeited with them, could have a better chance of protracting their days in ease, health and comfort.

HELENA ISLAND, St, on the coast of S. Carolina, with the continent on the north, forms St Helena Sound or Entrance, and gives name to a parish in Beaufort district.—*Morse.*

Helena Parish, St, in Beaufort district, S. Carolina, consists of a cluster of islands, on the S. W. side of St Helena Island, one of the largest of which is Port Royal. Adjacent to Port Royal are St Helena, Ladies, Paris, and Hunting Islands. The Hunting Islands are 5 or 6 in number, bordering on the ocean, so called from the number of deer and other game found upon them. All these islands, and some others of less note belong to this parish. The produce of the islands is rice, indigo, cotton, corn, and sweet potatoes; the cultivation of which, as well as in other parts of the State, is entirely carried on by slaves. Taxes paid by St Helena parish £1,144 : 13 : 2. Chief town, Beaufort, on Port Royal island.—*ib.*

Helena, St, a town on the coast of Florida, built by the Spaniards, and burnt by Sir Francis Drake in 1585.—*ib.*

HELICOID Parabola, or the *Parabolic Spiral* is a curve arising from the supposition that the common or Apollonian parabola is bent or twisted, till the axis come into the periphery of a circle, the ordinates still retaining their places and perpendicular positions with respect to the circle, all these lines still remaining in the same plane.

HELISPHERICAL Line, is the Rhumb line in Navigation; being so called, because on the globe it winds round the pole helically or spirally, coming still nearer and nearer to it.

HELL GATE, this celebrated strait is near the west end of Long Island Sound, opposite to Harlem in York Island, and about 8 miles north-east of New-York city, and is remarkable for its whirlpools, which make a tremendous roaring at certain times of the tide. These whirlpools are occasioned by the narrowness and crookedness of the passage, and a bed of rocks which extend quite across it; and not by the meeting of the tides from east to west, as has been conjectured, because they meet at Frog's Point, several miles above. A skilful pilot may conduct a ship of any burden, with safety, through this strait, at high water with the tide, or at low water with a fair wind. There is a tradition among the Indians, that in some distant period, in former times, their ancestors could step from rock to rock, and cross this arm of the sea on foot at Hell Gate.—*Morse.*

HEMLOCK, a lake in New-York State, 12 miles long, and 1 broad, in the Gennessee country.—*ib.*

HEMPFIELD, the name of two townships in Pennsylvania, the one in Lancaster county, the other in that of Westmoreland.—*ib.*

HENDERSON'S GRANT, a tract 12 miles square, on the peninsula formed by the junction of Green river with the Ohio, in the State of Kentucky.—*ib.*

HENIOCHAS, or Heniochus, a northern constellation, the same as Auriga, which see *Encycl.*

HENLEY HOUSE, a station of the Hudson's Bay Company, on the north bank of Albany river, in New S. Wales, 150 miles S. W. of Albany Fort, and 110 N. W. by W. of Brunswick House. N. lat. 51° 14′ 27″. W. long. 85° 5′ 54″.—*Morse.*

HENNIKER, a township in Hillsborough county, New-

New-Hampshire, about 12 miles west of Concord. In 1775, it contained 367, and in 1790, 1127 inhabitants.—*ib.*

HENLOPEN, CAPE, forms the S. W. side of the entrance of Delaware Bay, and Cape May the N. E. side, 28 miles apart. Cape Henlopen lies in N. lat. 38° 50′, and in W. long. 75° 26′. There is a light-house here, a few miles below the town of Lewis, of an octagon form, handsomely built of stone 115 feet high, and its foundation is nearly as much above the level of the sea. The lantern is between 7 and 8 feet square, lighted with 8 lamps, and may be seen in the night 10 leagues off at sea. Its annual expense is about £650. There is a strong iron net-work, in order to prevent birds from breaking the glass at night. Yet so attractive is the light to the winged tribe, that shortly after its erection, 110 birds of different kinds were found dead one morning, and a duck, in particular flew against it with such force, as to penetrate through both the wire and glass, and was found dead in the lantern. Since the above accident, few similar ones have occurred, and the birds have become more wary.

Vessels off the Delaware, upon displaying a jack at the foretopmast-head, will be immediately furnished with a pilot. None, however, are to be depended upon, unless they are furnished with branches, and with a certificate from the board of wardens of Philadelphia.—*ib.*

HENRICO, a county of Virginia, about 30 miles long, and 7 broad, contains 12,000 inhabitants, including 5819 slaves. It is surrounded by Hanover, Charles City, and Goochland counties, and James river. A number of coal mines are in the county, and pits have been opened by many of the proprietors, and worked to considerable profit. The coals in several of the pits are found nearly 200 feet above the level of the river, and 3 or 4 feet below the surface of the ground. It is supposed that 500,000 bushels might be raised from one of these in a year. Chief town, Richmond.—*ib.*

HENRIQUELLE, a remarkable salt-pond in the Spanish part of the island of St. Domingo, about 22 leagues in circuit. It is inhabited by lizards and alligators, and land tortoises, all of a large size. The water is deep, clear, bitter and salt, and has a disagreeable smell. Near the middle of this pond is an island about 2 leagues long, and a league wide, in which is a spring of fresh water, well stocked with *cabritoes*, and thence called *Cabrito island*. This pond is about 11 leagues E. of Port-au-Prince.—*ib.*

HENRY, a cape, the north-eastern extremity of Princess Ann county, in Virginia, 12 miles S. by W. of Cape Charles in Northampton county. These capes form the entrance of Chesapeak Bay. Cape Henry lies in N. lat. 37°, W. long. 76° 16′.—*ib.*

HENRY, a fort in Pennsylvania, 8 miles N. by W. of Myer's Town, at the head of Tulpehocken creek, 32 N. of Lancaster, and nearly 37 S. E. of Sunbury.—*ib.*

HENRY, a mountainous and hilly county of Virginia, bounded N. by Franklin, S. and S. E. by Patrick, S. W. by Grifon, and N. W. and W. by Montgomery. It is about 40 miles long, 15 broad, and contains 6928 inhabitants, including 1551 slaves.—*ib.*

HERKEMER, a new county of New-York, divided into 20 townships, viz. German Flats, Warren, Frankfort, and Litchfield, formed out of *German Flats* in Feb. 1796. Herkemer, Fairfield and N[illegible], formed out of *Fairfield*, Feb. 1796.—Schuyler. The following were comprehended originally in *H[illegible]*, viz. Paris, Sangerfield, Hamilton, Sherburn, Brookfield, Cazenovia, Westmoreland, Mexico, Rome, Steuben and Floyd. By the State census of 1796 the county contains 25,573 inhabitants, of whom 4161 are electors. It is bounded N. by part of Lower Canada and the river St Lawrence, N. W. by the E. end of Lake Ontario, and the river St Lawrence; S. by Otsego county; E. by Clinton and part of Washington county.—*ib.*

HERKEMER TOWN, in the above county, is situated on the north side of Mohawk river. The township includes the village called Little German Flats, and the celebrated plain called German Flats. The village contains a court-house, gaol, a Dutch church, and about 40 dwelling houses, which last are very indifferent buildings. It is 80 miles N. W. by W. of Albany, 16 S. E. of old Fort Schuyler, and 20 in a like direction from Whitestown. In the midst of the flats is a shrub oak plain of 80 or 100 acres, barren and [illegible], of no use but for building lots. The township is named in honour of general Herkemer, who was mortally wounded in the late war. It contained in 1796, by the State census, 2073 inhabitants; of whom [illegible] were electors.—*ib.*

HERO, NORTH, an island in Lake Champlain, is a township annexed to Chittenden county in Vermont, and contains 125 inhabitants. It is 13 miles in length, and 2 in breadth.—*ib.*

HERO, SOUTH, an island in the same lake, belonging to Chittenden county, Vermont, is a township and port of entry, and contains 537 inhabitants. It is 14 miles long, and 3½ broad. Numerous small isles surround the Heros. This island produces good crops of wheat and other grain. In it is a quarry of [illegible] grey marble, which has the appearance of being a petrifaction of scallops, a species of shell common in the vicinity of the lake, together with the common earth of the shore, which is [illegible].—*ib.*

HERON, PASS AU, at the bay of Mobile, in W. Florida, is 18 miles E. of [illegible] river, and has 4 feet water; and from thence to the [illegible] the E. side of the bay of Mobile, in N. lat. [illegible] is nearly 6 miles.—*ib.*

HERRING BAY, lies on the W. side of Chesapeak Bay, Maryland, 26 miles [illegible] and derives its name from the [illegible] quent it.—*ib.*

HERSCHEL, the name [illegible] and most other European nations, call [illegible] discovered by Dr Herschel in the year [illegible]. [illegible] or character is H. The [illegible] call it Uranus, or Urania; but the English, the Georgium [illegible], or Georgium Sidus.

HERTFORD, a county of Edenton district, N. Carolina; bounded N. by the State of Virginia, S. by Bertie county, E. by Chowan, and W. by Northampton, and contains [illegible] inhabitants, of whom [illegible] are slaves. Chief town, Wynton.—*M[illegible]*

HETERODROMUS VECTIS, or LEVER, in Mechanics, a lever in which the fulcrum or point of suspension is between the weight and the power; being the same as what is otherwise called a lever of the first kind.

HIATSTOWN, a village in Middlesex county, New-Jersey; 13 miles northeasterly of Trenton, and 17 S. by W. of New-Brunswick.—*Morse.*

HICKMAN'S, a settlement in Fayette county, Kentucky, on the N. side of Kentucky river, 10 miles N. of Danville, and 22 S. of Lexington.—*ib.*

HID ISLAND is situated in the N. W. Territory; in Plein river, the northern head water of the Illinois. —*ib.*

HIGHGATE, a village in Georgia, about 4 miles from Savannah.—*ib.*

HIGHGATE, the north-westernmost township except Alburgh, in Vermont, in Franklin county, contains 103 inhabitants.—*ib.*

HIGHLANDS, a mountainous tract of country on the banks of Hudson's river, in the State of New-York, between 40 and 60 miles N. of New-York city. The passage on the river through these Highlands, for the distance of about 18 miles, is grand and romantic in a high degree. The opening seems to have been formed on purpose for the passage of this noble river. In these highlands are situated the important and famous fortresses of West Point, Fort Montgomery, and Stoney Point. The most noted peaks are, as you ascend the river, Thunder Hill, St Anthony's Nose, Sugar Loaf, Butter Hill, and Break Neck Hill. After passing the two last, the country opens delightfully, and presents to the eye the pleasant villages of New-Windsor and Newburgh. These mountains abound with iron ore.—*ib.*

HIGUEY, or *Alta Gracia*, a city in the S. E. part of the Spanish division of St Domingo, the easternmost of all the settlements in the island, celebrated formerly for its fertility, and the quantity of sugar it produced. It was formerly the seat of *Cayacoa*, the most powerful cacique of the island. It has now only about 500 inhabitants, and is distant about 40 leagues to the eastward of St Domingo, between which and Higuey are three roads, the circuitous and northernmost of which leads by Bayaguana. N. lat. 18° 30'.—*ib.*

HILLSBOROUGH, an island on the Labrador coast, on a bay at the head of which is Nain.—*ib.*

HILLSBOROUGH, a county of New-Hampshire, bounded N. by Grafton county, S. by the State of Massachusetts, W. by Cheshire, and E. by Rockingham county.

It is divided into 37 townships and 4 gores of land, which contain 32,871 inhabitants, all free people, who chiefly follow agriculture. The academy at Amherst, has £800 funds, and another at New-Ipswich of £1000. Chief towns, Amherst and Hopkinton.—*ib.*

HILLSBOROUGH, a township in the above county, situated on the northern head branches of Contocook river, about 18 or 20 miles W. of Concord, was incorporated in 1772, and contains 798 inhabitants.—*ib.*

HILLSBOROUH, a township in Somerset county, New-Jersey, containing 2,201 inhabitants, including 386 slaves. It is about 15 miles W. of Brunswick, and 18 northerly of Trenton.—*ib.*

HILLSBOROUGH, a village on the eastern side of Chesapeak Bay, in Caroline county, Maryland; seated on the E. side of Tuckahoe Creek, one of the chief branches of Choptank river, 7 miles S. E. by E. of Denton, 9 N. W. of Greensborough, and 27 S. S. W. of Chester.—*ib.*

HILLSBOROUGH, one of the middle districts of North-Carolina, bounded N. by the State of Virginia, S. by Fayetteville district, E. by Halifax, and W. by Salisbury. It comprehends the counties of Granville, Person, Caswell, Orange, Wake, Chatham, and Randolph; and contains 59,983 inhabitants, of whom 13,506 are slaves. Chief town, Hillsborough.—*ib.*

HILLSBOROUGH, a post-town of North-Carolina, and capital of the district of its name, is situated in Orange county, on the N. side of Eno river, in a high, healthy and fertile country. It contains about 80 houses, a court-house and gaol; and had in 1788 an academy of 60 or 80 students, patronized by the principal gentlemen of the State. The Eno unites with Little and Flat rivers, and forms the Neus, about 17 miles below the town. It is 180 miles W. N. W. of Newbern, 26 S. by W. of Person court-house, 101 W. by S. of Halifax, 110 E. N. E. of Salisbury, and 452 S. W. by S. of Philadelphia.—*ib.*

HILLSDALE, a township in Columbia county, New-York, 18 miles from Hudson city, containing 4556 inhabitants, including 31 slaves. By the State census of 1796, 622 of the inhabitants are electors.—*ib.*

HILLTOWN, a small town near the centre of Chester county, Pennsylvania; 28 miles W. of Philadelphia, and 21 N. W. of Chester. Also the name of a township in Bucks county in the same State.—*ib.*

HILTON HEAD is the most southern sea land in S. Carolina. W. and S. W. of Hilton Head lie Pinckney's Bulls, Dawfuskies and some smaller islands, between which and Hilton Head, are Calibogie river and sound, which form the outlet of May and New rivers.—*ib.*

HILTON'S POINT, in Pascataqua river, in New-Hampshire, is the spot where the united stream of Newichawannock and Cochecho rivers, which comes from Dover, meets the western branch and forms the Piscataqua: From thence to the sea is 7 miles, the course generally S. to S. E. and the river is so rapid that it never freezes.—*ib.*

HINCHE, a territory and town in the Spanish part of St Domingo. The canton of Hinche is bounded W. by the French parishes of Gonaives, Petit Riviere and Mirebalais—and contains with some appendages about 12,000 souls. The town contains about 500 houses, and, together with its dependencies, 4,500 souls, 500 of whom are capable of bearing arms. It is situated on the E. side of the mouth of the river Guayamuco, 64 miles N. W. of St Domingo, N. lat. 19° 3'.—*ib.*

HINESBURGH, a township in Chittenden county, in Vermont, lies E. of and joins Charlotte on Lake Champlain. It contains 454 inhabitants.—*ib.*

HINGHAM, a post-town in Suffolk county, Massachusetts, situated on a small bay which sets up south from Boston Bay. It contains a number of houses compactly built, two Congregational churches, and a well endowed school, called, in honour of its principal donor

donor and founder, Derby School. It is 19 miles S. E. of Bofton, and 22 in a like direction from Plymouth. The townfhip is about 4 miles fquare, confifts of two parifhes, was incorporated in 1635, and contains 2,085 inhabitants. Here are 6 grift-mills, 3 faw-mills, and a fulling-mill; four of which are tide mills. Two hills in this town, one of which is called Baker's Hill, prefent extenfive and delightful profpects of Bofton Bay, its iflands, and the adjacent country.—*ib.*

HINSDALE, the S. eafternmoft townfhip in Vermont, and in Windham county. It contains 482 inhabitants.—*ib.*

HINSDALE, a townfhip in Chefhire county, New-Hampfhire, on the eaft bank of Connecticut river, where the fouth line of the State ftrikes the river in 42° 43′ 59″ N. lat. and is oppofite to Hinfdale in Vermont. It was incorporated in 1753, and contains 522 inhabitants. It is about 38 miles above Northampton.—*ib.*

HINZUAN, the proper name of one of the Comora iflands, which by different writers of different nations has been called *Anzuame, Anjuan, Juanny*, and *Johanna*, and which is defcribed in the *Encyclopædia* under the name of St Joanna. In that article, it is obferved, that an anonymous writer has cenfured the defcriptions of this ifland given by the Abbé Reynal and Major Rooke, as being not only exaggerated, but erroneous; neither the country being fo picturefque as the former reprefents it, nor the inhabitants meriting the refpectable character given of them by the latter.

There was not perhaps much propriety in admitting into fuch a work as the *Encyclopædia* the anonymous cenfure of defcriptions, authenticated by the names of refpectable authors; but the beft reparation which we can make to thofe authors, is, to inform our readers, that their defcriptions of Hinzuan are confirmed by Sir William Jones, whofe teftimony, we believe, no man will controvert. That accomplifhed fcholar, who vifited the ifland on his voyage to India, thus defcribes its appearance from the bay in which the fhip rode at anchor.

"Before us was a vaft amphitheatre, of which you may form a general notion by picturing in your minds a multitude of hills infinitely varied in fize and figure, and then fuppofing them to be thrown together, with a kind of artlefs fymmetry, in all imaginable pofitions. The back ground was a feries of mountains, one of which is pointed, near half a mile perpendicularly high from the level of the fea, and little more than three miles from the fhore, all of them richly clothed with wood, chiefly fruit trees, of an exquifite verdure. I had feen many a mountain of ftupendous height in Wales and Swifferland, but never faw one before, round the bofom of which the clouds were almoft continually rolling, while its green fummit rofe flourifhing above them, and received from them an additional brightnefs. Next to this diftant range of hills was another tier, part of which appeared charmingly verdant, and part rather barren; but the contraft of colours changed even this nakednefs into a beauty: nearer ftill were innumerable mountains, or rather cliffs, which brought down their verdure and fertility quite to the beach; fo that every fhade of green, the fweeteft of colours, was difplayed at one view by land and by water. But nothing conduced more to the variety of this enchanting profpect, than the many rows of palm-trees, efpecially the tall and graceful *Arecas*, on the fhores, in the valleys, and on the ridges of hills, where one might almoft fuppofe them to have been planted regularly by defign. A more beautiful appearance can fcarce be conceived, than fuch a number of elegant palms in fuch a fituation, with luxuriant tops, like verdant plumes, placed at juft intervals, and fhowing between them part of the remoter landfcape, while they left the reft to be fupplied by the beholder's imagination. The town of *Matfamúdò* lay on our left, remarkable at a diftance for the tower of the principal mofque, which was built by Halímah, a queen of the ifland from whom the prefent king is defcended: a little on our right was a fmall town called *Bantàni*. Neither the territory of *Nice*, with its olives, date trees and cypreffes, nor the ifles of *Hieres*, with their delightful orange groves, appeared fo charming to me, as the view from the road of *Hinzúàn*."

Sir William Jones, fpeaking of the inhabitants, takes notice of the *Lords, Dukes* and *Princes*, of whom we have made mention after major Rooke. "The frigate, (fays he) was prefently furrounded with canoes, and the deck foon crowded with natives of all ranks, from the high born chief, who wafhed linen, to the half-naked flave who only paddled. Moft of them had letters of recommendation from Englifhmen, which none of them were able to read, though they fpoke Englifh intelligibly; and fome appeared vain of titles, which our countrymen gave them in play, according to their fuppofed ftations: we had *Lords, Dukes*, and *Princes* on board, foliciting our cuftom, and importuning us for prefents. In fact, they were too fenfible to be proud of empty founds, but juftly imagined, that thofe ridiculous titles would ferve as marks of diftinction, and, by attracting notice, procure for them fomething fubftantial." He fpeaks with great refpect of the king, whofe name was *Ahmed*, as well as of feveral chiefs whom he faw, and feems to have met with no man of rank on the ifland whofe character was contemptible, but Selim the king's eldeft fon. For the behaviour of that prince, the old fovereign made the beft apology that he could, while he privately affured the interpreter, that he was much difpleafed with it, and would not fail to exprefs his difpleafure. He concluded his converfation with a long harangue on the advantage which the Englifh might derive from fending a fhip every year from Bombay to trade with his fubjects, and on the wonderful cheapnefs of their commodities, efpecially of their cowries. Ridiculous as this idea might feem, it fhowed (fays Sir William) an enlargement of mind, a defire of promoting the intereft of his people, and a fenfe of the benefits arifing from trade, which could hardly have been expected from a petty African chief, and which, if he had been fovereign of Yemen, might have been expanded into national projects proportioned to the extent of his dominions.

The mafter of the frigate learned from one of the chiefs a few curious circumftances concerning the government of *Hinzuan*: which he found to be a monarchy limited by an ariftocracy. The king, he was told, had no power of making war by his own authority; but, if the affembly of nobles, who were from time to time convened by him, refolved on a war with any of the neighbouring iflands, they defrayed the charges

of

of it by voluntary contributions; in return for which, they claimed as their own all the booty and captives that might be taken. The hope of gain or the want of slaves, is usually the real motive for such enterprises, and ostensible pretexts are easily found: at that very time, he understood they meditated a war, because they wanted hands for the following harvest. Their fleet consisted of sixteen or seventeen small vessels, which they manned with about two thousand five hundred islanders, armed with muskets and cutlasses, or with bows and arrows. Near two years before they had possessed themselves of two towns in *Mayóta*, which they still kept and garrisoned. The ordinary expences of the government were defrayed by a tax from two hundred villages; but the three principal towns were exempt from all taxes, except that they paid annually to the chief *Mufti* a fortieth part of the value of all their moveable property, and from that payment neither the king nor the nobles claimed an exemption. The kingly authority, by the principles of their constitution, was considered as elective, though the line of succession had not in fact been altered since the first election of a sultan.

Sir William Jones concludes his remarks on this island with some reflections; of which, though they may be considered as digressive, we are persuaded our readers will approve of our extending the circulation.

"We have lately heard of civil commotions in *Hinzuan*, which, we may venture to pronounce, were not excited by any cruelty or violence of Ahmed, but were probably occasioned by the insolence of an oligarchy naturally hostile to king and people. That the mountains in the *Comara* islands contain diamonds, and the precious metals, which are studiously concealed by the policy of the several governments, may be true, though I have no reason to believe it, and have only heard it asserted without evidence; but I hope, that neither an expectation of such treasures, nor of any other advantage, will ever induce an European power to violate the first principles of justice by assuming the sovereignty of *Hinzuan*, which cannot answer a better purpose than that of supplying our fleets with seasonable refreshment; and, although the natives have an interest in receiving us with apparent cordiality, yet, if we wish their attachment to be unfeigned and their dealings just, we must set them an example of strict honesty in the performance of our engagements. In truth, our nation is not cordially loved by the inhabitants of *Hinzuan*, who, as it commonly happens, form a general opinion from a few instances of violence or breach of faith. Not many years ago an European, who had been hospitably received and liberally supported at *Matsamudo*, behaved rudely to a young married woman, who, being of low degree, was walking veiled through a street in the evening: her husband ran to protect her, and resented the rudeness, probably with menaces, possibly with actual force; and the European is said to have given him a mortal wound with a knife or bayonet, which he brought, after the scuffle, from his lodging. This foul murder, which the law of nature would have justified the magistrate in punishing with death, was reported to the king, who told the governor (I use the very words of Alwi a cousin of the king's), that "it would be wiser to hush it up." Alwi mentioned a civil case of his own, which ought not to be concealed. When he was on the coast of Africa in the dominions of a very savage prince, a small European vessel was wrecked; and the prince not only seized all that could be saved from the wreck, but claimed the captain and the crew as his slaves, and treated them with ferocious insolence. Alwi assured me, that, when he heard of the accident, he hastened to the prince, fell prostrate before him, and by tears and importunity prevailed on him to give the Europeans their liberty; that he supported them at his own expence, enabled them to build another vessel, in which they sailed to *Hinzuan*, and departed thence for Europe or India: he shewed me the captain's promissory notes for sums, which to an African trader must be a considerable object, but which were no price for liberty, safety, and, perhaps, life, which his good, though disinterested offices had procured. I lamented that, in my situation, it was wholly out of my power to assist Alwi in obtaining justice; but he urged me to deliver an *Arabic* letter from him, enclosing the notes, to the governor-general, who, as he said, knew him well; and I complied with his request. Since it is possible, that a substantial defence may be made by the person thus accused of injustice, I will not name either him or the vessel, which he had commanded; but, if he be living, and if this paper should fall into his hands, he may be induced to reflect how highly it imports our national honour, that a people, whom we call savage, but who administer to our convenience, may have no just cause to reproach us with a violation of our contracts."

HIPS, in architecture, are those pieces of timber placed at the corners of a roof. These are much longer than the rafters, because of their oblique position. Hip means also the angle formed by two parts of the roof, when it rises outwards.

Hip-Roof, called also Italian roof, is one in which two parts of the roof meet in an angle, rising outwards: the same angle being called a valley, when it sinks inwards.

HIRCUS, in astronomy, a fixed star of the first magnitude, the same with capella.

Hircus is also used by some writers for a comet, encompassed as it were with a mane, seemingly rough and hairy.

HIRUDO. See *Encycl.* A new species of this insect was discovered in the South Sea by Le Martiniere, naturalist in Perouse's voyage of discovery. He found it buried about half an inch in a shark's liver, but could not conceive how it had got thither. It was something more than an inch long, of a whitish colour, and composed of several rings similar to those of the tænia. The superior part of its head was furnished with four small ciliated mamillæ, by which it took its food; under each mamilla on both sides was a small oblong pouch, in the form of a cup; and in the form of its *instrumenta cibaria*, it very nearly resembles the animal which has been supposed to be the cause of measles in swine. Both these species are referable to the genus *hirudo*, the characters of which, as given by Linnæus, stand (says Martiniere) in need of reformation.

HIRUNDO Esculenta (see Hirundo, *Encycl.* n° 3.), is thus described in the *Transactions of the Batavian Society in the Island of Java*, vol. iii.; and the description confirms the sagacious conjecture of Mr Latham

Hirundo || Hispaniola.

Latham respecting the size of the bird, which the reader will find in our article referred to.

"The hirundo esculenta is of a blackish grey colour, inclining a little to green; but on the back to the tail, as well as on the belly, this blackish colour gradually changes into a mouse colour. The whole length of the bird from the bill to the tail is about four inches and a half, and its height from the bill to the extremity of the middle toe three inches and a quarter. The distance from the tip of the one wing to that of the other, when extended, is ten inches and a quarter. The largest feathers of the wings are about four inches in length. The head is flat; but, on account of the thickness of the feathers, appears round, and to be of a large size in proportion to the rest of the body. The bill is broad, and ends in a sharp extremity, bent downwards in the form of an awl. The width of it is increased by a naked piece of skin somewhat like parchment, which, when the bill is shut, lies folded together; but which, when the bill opens, is considerably extended, and enables the bird to catch with greater ease, while on wing, the insects that serve it for food. The eyes are black, and of a considerable size. The tongue, which is not forked, is shaped like an arrow. The ears are flat, round, naked spots, with small oblong openings, and are entirely concealed under the feathers of the head. The neck is very short, as well as the legs and the bones of the wings. The thighs are wholly covered with feathers; and the very tender lower parts of the legs, and the feet themselves, are covered with a skin like black parchment. Each foot has four toes, three of which are before and one turned backwards. They are all detached from each other to the roots; and the middle one, together with the claw, is fully as long as the lower part of the leg. Each toe is furnished with a black, sharp, crooked claw of a considerable length, by which the animal can with great facility attach itself to crags and rocks. The tail is fully as long as the body together with the neck and the head. When expanded it has the form of a wedge, and consists of ten large feathers. The four first on each side are long; and, when the tail is closed, extend almost an inch beyond the rest. The other feathers decrease towards the middle of the tail, and are equal to about the length of the body."

There is a variety of this species of hirundo, with a speckled breast, and white spots on the tail feathers; and this, though less numerous than the other, and indeed not found at all in Java, appears to have been the only hirundo esculenta known to Linnæus. For an account of the eatable nests of these birds, and the manner of collecting them, see CAP and BUTTON in this *Supplement*.

HISPANIOLA, or ST DOMINGO, the largest of the Antilles or Caribbee islands, has been described, as it existed prior to the French revolution, in the *Encyclopædia*. Previous to the year 1789 the government of the French part of the island was administered by an officer called the Intendant, and a Governor-General, both nominated by the crown, and invested with authority for three years. Their powers were in some cases distinct, and in others united; but though these powers were extensive and almost absolute, the attention which the old government of France paid to the character and rank of those persons whom it had placed over its foreign settlements, secured to the inhabitants of Hispaniola a very considerable share of happiness. In spite of what our restless innovators call political evils, signs of prosperity were everywhere visible; their towns were opulent, their markets plentiful, their commerce extensive, and their cultivation increasing.

Hispaniola.

Such was, in 1788, the state of the French colony in the island of St Domingo; but in that eventful year, the flame, which had burst forth in Europe, spread itself to the West-Indies. An association had been formed in France upon principles somewhat similar to those of our society for the abolition of the slave trade; but that association, which called itself *Amis des Noirs*, had much more dangerous designs than ours. Avowing its detestation of every kind of slavery, as well as of the African trade, and condemning those abettors of liberty who dared to declare themselves poss[illegible], its members kept up an intimate and clandestine connection with those rich mulattoes who resided in France for their education, and laboured to convince them that neither their colour nor their *spurious birth* [illegible] make any civil or political distinction between them and the whites who were born in [illegible]. [illegible], as it were, with these factions and [illegible], the National Assembly issued its [illegible] declaration, in which it was maintained that all men [illegible] and continue free, and equal in their rights. The consequence of this was such as might have been expected. The mulattoes of Hispaniola instructed in the French philosophy of the rights of man, broke out into rebellion; but not acting in concert, they were quickly overpowered.

The spirit, however, which had been excited among them, still continued to ferment; and the National Assembly of France, taking the state of the island into solemn consideration, decreed, by a great [illegible], that its intention had never been to interfere with the internal affairs of the colony; that their internal legislation was entirely their own; and that the legislature of the mother country would make no innovation, directly or indirectly, in the system of commerce in which the colonies were already concerned. [illegible] grateful this declaration might be to the whites of St Domingo, and in the then state of things however wise in itself, it occasioned discontent and [illegible] on the part of the factious friends of the negroes. They regarded it as an unwarrantable [illegible] of the African traffic, and a confession, that the planters of Hispaniola were not colonists, but an independent people.

The colonists themselves, indeed, [illegible] representatives, seem to have [illegible] they were rendered independent; [illegible] assembly they passed an act [illegible] gate, the governor general, [illegible] their future acts. This [illegible] giving universal [illegible] called their delegates, [illegible] nounced their obedience to [illegible], and petitioned the governor [illegible].

During these [illegible] the line, which lay in [illegible] gave a sumptuous entertainment [illegible] governor; on which [illegible] themselves in the [illegible] to mutiny; and [illegible], in [illegible] thanks to the mutineers. [illegible] ing at the ſame time a powder magazine, the governor declared them adherents to traitors, and called on all officers, civil and military, to bring them to puniſhment. This was the ſignal for civil inſurrection; armed troops took the field on both ſides; and war ſeemed inevitable, when the aſſembly reſolved to repair in a body to France and juſtify their paſt conduct.

In the mean time the *Amis des Noirs* contrived to excite the people of colour to rebellion. They initiated in the doctrine of equality and the rights of man one James Oge, then reſiding in Paris in ſome degree of affluence. They perſuaded him to go to St Domingo, put himſelf at the head of his people, and deliver them from the oppreſſion of the whites; and in order to evade the notice of government, they undertook to procure for him arms and ammunition in America. He embarked accordingly, July 1790, for New England with money and letters of credit; but notwithſtanding the caution of the *Amis des Noirs*, his deſigns were diſcovered by the French government, and his portrait was ſent out before him to St Domingo. He landed on the iſland in October, and ſix weeks afterwards publiſhed a manifeſto, declaring his intention of taking up arms, if the privileges of whites were not granted to *all perſons without diſtinction*. He was joined by about 200 men of colour; and this little army of ruffians not only maſſacred the whites wherever they fell in with them in ſmall numbers, but, by a ſtill more unjuſtifiable mode of conduct, took vengeance on thoſe of their own colour who refuſed to join their rebellious ſtandard. They were, however, ſoon overpowered by the regular troops; and their leader, after diſcloſing, it is ſaid, ſome important ſecrets, ſuffered the puniſhment due to his treaſon.

While theſe things were going on in the iſland, the members of the Colonial Aſſembly arrived at Paris, where they were received by the repreſentatives of the French people with marked ſymptoms of averſion. The reſolutions compoſing their famous decree were pronounced improper; their vote of thanks to the mutineers was declared criminal; they were themſelves perſonally arreſted; orders were given for a new aſſembly to be called; and the king was requeſted to augment the naval and military force then at St Domingo.

The National Aſſembly of France having decreed that every perſon twenty-five years old and upwards, poſſeſſing property, or having reſided two years in the colony and paid taxes, ſhould be permitted to vote in the formation of the colonial aſſembly, the people of colour very naturally concluded that this privilege was conferred upon them. Such, however, we believe, was not the meaning of the National Aſſembly; but Gregoire, with the other friends of the negroes, at laſt prevailed, and mulattoes born of free parents were pronounced to be not only worthy of chooſing their repreſentatives, but alſo eligible themſelves to ſeats in the colonial aſſemblies. This decree ſacrificed at once all the whites in the iſland to the people of colour; and the indignation which filled the minds of both the royal and the republican parties ſeemed to have united them in one common cauſe. They reſolved to reject the civic oath; to confiſcate the French property in the harbour, on which they actually laid an embargo; to pull down the national colours, and to hoiſt the Britiſh ſtandard in their ſtead. The mulattoes in the mean time collected in armed bodies, and waited with anxious expectation to ſee what meaſures the colonial aſſembly would adopt.

During theſe diſſenſions, the negro ſlaves, into whoſe minds had been ſeduloufly inſtilled an opinion that their rights were equal to thoſe of their maſters, reſolved to recover their freedom. On the morning of the 23d of Auguſt 1791, the town of the Cape was alarmed by a confuſed report that the ſlaves in the adjoining pariſhes had revolted; and the tidings were ſoon confirmed by the arrival of thoſe who had narrowly eſcaped the maſſacre. The rebellion had broken out in the pariſh of Acul, nine miles from the city, where the whites had been butchered without diſtinction; and now the rebels proceeded from pariſh to pariſh, murdering the men, and raviſhing the unfortunate women who fell into their hands. In a ſhort time the ſword was accompanied with fire, and the cane-fields blazed in every direction. The citizens now flew to arms, and the command of the national troops was given to the governor, whilſt the women and children were put aboard the ſhips in the harbour for ſafety. In the firſt action the rebels were repulſed; but their numbers rapidly increaſing, the governor judged it expedient to act ſolely on the defenſive. In the ſpace of two months it was computed that upwards of 2000 white perſons periſhed; and of the inſurgents, who conſiſted as well of mulattoes as of negroes, not fewer than 10,000 died by famine and the ſword, and hundreds by the hands of the executioner.

When intelligence of theſe dreadful proceedings reached Paris, the Aſſembly began to be convinced that its equalizing principles had been carried too far; and the famous decree, which put the people of colour on the ſame footing with the whites, was repealed. Three commiſſioners were likewiſe ſent to the colony to reſtore peace between the whites and the mulattoes; but two of them being men of bad character, and none of them poſſeſſing abilities for the arduous taſk of extinguiſhing the flames of a civil war, they returned to France without accompliſhing in any degree the object of their miſſion.

In the mean time the *Amis des Noirs* in the mother country had once more gained the aſcendant in the National Aſſembly; and three new commiſſioners, Santhonax, Polverel, and Ailhaud, with 6000 choſen men from the national guards, were embarked for St Domingo. It was ſtrongly ſuſpected that the object of theſe commiſſioners was to procure unqualified freedom for all the blacks in the iſland; but they ſolemnly ſwore that their ſole purpoſe was to eſtabliſh the rights of the mulattoes, as decreed by the law which had been lately repealed. The whites therefore expected that a colonial aſſembly would be convoked; but inſtead of this the commiſſioners nominated twelve perſons, of whom ſix had been members of the laſt aſſembly, and ſix were mulattoes, *Une Commiſſion Intermediare*, with authority to raiſe contributions on the inhabitants, the application of which, however, they reſerved to themſelves. The governor finding that the commiſſioners uſurped all authority, complained that he was but a cypher in public affairs; his complaint was anſwered by an arreſt upon his perſon, and he was ſent a ſtate priſoner to France.

The tyranny of the commiſſioners did not ſtop here. They overawed the members of the commiſſion *intermediare*, by arreſting four of their number; and diſagreeing among themſelves, Santhonax and Polverel diſmiſſed

Hispaniola, || Hiwassee.

Hoboken || Holland.

missed Ailhaud from their councils. War was by this time declared between the mother country and Great Britain, and prudence compelled the government of France to take some care of the injured colony. Galbaud, therefore, a man of fair character, was appointed governor, and ordered to put the island in a state of defence against foreign invasion; but possessing West India property, which it seems was a legal disqualification for the office of governor, the commissioners disregarded his authority, and took up arms against him. Finding themselves likely to be worsted, they offered to purchase the aid of the rebel negroes, by the offer of a pardon for their past conduct, freedom in future, and the plunder of the capital. Two of the negro chiefs, more honourable than the French commissioners, spurned at the base proposal; but a third, after the governor had fled to the ships, entered the town with 3000 revolted negroes, and began an indiscriminate massacre. The miserable inhabitants fled to the shore, but their retreat was stopped by a party of mulattoes; and for two days the slaughter was incessant. The town was half consumed by fire; and the commissioners, terrified at the work of their own hands, fled for protection to a ship of the line, and thence issued a manifesto, which, while it tried to extenuate, evinced a consciousness of their guilt.

Thus was lost perhaps to Europe, and lost by the frantic conduct of French philanthropists, the finest island in the West Indies; an island which produced alone as much sugar as all the British West India possessions united; not to mention the coffee and indigo, which were in immense quantities cultivated in Hispaniola. Had it not been for the restless machinations of the *Amis des Noirs*, it does not appear that so general a revolt would have taken place among the slaves; for though the spirit of republicanism had found its way into the island, the republicans joined with the royalists to keep the negroes in proper subjection. The unsuccessful attempt which, at the request of the more respectable part of the inhabitants, the British government made to subdue the execrable commissioners and their adherents, is fresh in the memory of all our readers, and need not here be detailed at length. Suffice it to say, that after prodigies of valour, our troops were compelled, rather by disease than by the swords of the enemy, to abandon the island, which is now under the controul of a negro or mulatto-chief. What will ultimately become of it, future events must decide; but let its protracted and bloody disputes be a warning to all, and among others to our association for the abolition of the slave trade, that it is impossible to promote a good end by wicked means, and that slaves must be civilized before they be made free.

HITCHELAGA, or *Hochelaga*, an Indian village in Lower Canada, situated in the island of Montreal, and at the foot of the mountain so called. It is fortified after the Indian manner, and the inhabitants speak the Huron language.—*Morse.*

HITTON, a small village in Anne Arundel county, Maryland, 13 miles W. by S. of Baltimore.—*ib.*

HIWASSEE is the only river of any consequence which empties into the Tennessee from the south. It is a bold river, passing through the Cherokee towns and empties into the Tennessee about 40 miles below the mouth of the Clinch, and 46 above the Whirl or Suck, by land, but 60 by water. It is navigable till it penetrates the mountains on its S. side. Ore was found in these mountains, when in possession of the British, from which gold was extracted. The Indians know the spot; but are very anxious to keep it a secret. A branch of the Hiwassee, called Amoia, almost interlocks a branch of the Mobile. The portage between them is short, and the road firm and level.—*ib.*

HOBOKEN, a tract of land in Bergen county, New-Jersey, situated on the W. bank of the Hudson, in the mountainous country between the town of Bergen and Fort Lee, about 7 miles above New-York city.—*ib.*

HOCKHOCKING, a river in the N. W. Territory, about 28 miles below the Muskingum, which it resembles, but is inferior to it in size. It rises near a branch of the Sciota, and taking a S. W. course enters the Ohio at Bellpre, in N. lat. 38° 57′. It is navigable for large flat bottomed boats, between 70 and 80 miles; has fine meadows with high banks, which are seldom overflowed, and rich uplands on its borders. On the banks of this fine river are inexhaustible quarries of free-stone, large beds of iron ore, rich mines of lead, and coal pits. There are also productive salt springs, beds of white and blue clay of an excellent quality. Red bole, and many other useful fossils have been found on the banks of this river.—*ib.*

HOLDEN, a township in Worcester county, Massachusetts, was formerly the north-western part of Worcester, from which it is distant 7 miles, and 51 miles W. of Boston. It contains 1080 inhabitants. It was incorporated in 1740. In the earthquake in 1755, there were several acres of land, in an obscure place in the N. E. corner of the township, quite surrounded by a visible fracture in the earth, of a circular form, and of various width and depth. The small river there had its bed raised so as to occasion a considerable fall of water, where there was little or none before. The stump of a tree, that stood directly over the chasm, on the E. was divided into two equal parts, one standing on the outside of the chasm, the other upon the inside; but not opposite to each other: the half within the chasm, being carried 5 feet forward, towards the river.—*ib.*

HOLDERNESS, a township in Grafton county, New-Hampshire, situated on the eastern side of Pemigewasset river, was incorporated in 1761, and contains 329 inhabitants. A corner of Squam Lake is in this township; and Rattlesnake Mountain lies partly in this and Sandwich the adjoining township on the N. E. It is 64 miles N. N. W. of Portsmouth.—*ib.*

HOLE-IN-THE-WALL, a village in Talbot county, Maryland, on the E. side of Chesapeak bay; 7 miles easterly of Oxford, and a like distance S. of Easton.—*ib.*

HOLLAND, a township in Hampshire county, Massachusetts, which, until incorporated in 1785, was the E. parish of South Brimfield, and is bounded S. by Tolland county, in Connecticut, E. by Worcester county, and northward by Brimfield. It contains 428 inhabitants, and is 75 miles S. W. by W. of Boston.—*ib.*

Holland *Company Lands*, are situated in Pennsylvania, on the navigable waters of Alleghany river and French Creek.—*ib.*

HOLLAND'S *Islands* are near to, and south of Hooper's Island and Straits in Chesapeak Bay.—*ib.*

HOLLAND'S *Point*, on the west side of Chesapeak Bay, together with Parker's Island, form the mouth of Herring Bay.—*ib.*

HOLLIS, the *Nisitissit* of the Indians, a township in Hillsborough county, New-Hampshire, situated on the Massachusetts line, incorporated in 1746, and contains 1441 inhabitants. It is about 70 miles S. W. of Portsmouth, and 45 N. W. of Boston.—*ib.*

HOLLIDAYS *Island* lies 15 miles up Chowan river in North Carolina: Thus far the river is three miles wide.—*ib.*

HOLLISTON, the most southern township in Middlesex county, Massachusetts, has Hopkinton on the north, Wrentham on the east, and is 24 miles S. by W. of Boston. The first settlements were made here in 1710, and in 1724 the town was incorporated by its present name in honour of Thomas Hollis of London, one of the patrons of Cambridge University; and it now contains 875 inhabitants.—*ib.*

HOLLOW, in architecture, a concave moulding, about a quarter of a circle, by some called a casement, by others an abacus.

Hollow-Tower, in fortification, is a rounding made of the remainder of two brisures, to join the curtain to the crillon, where the small shot are played, that they may not be so much exposed to the view of the enemy.

HOLSTON, the largest branch of Tennessee river, rises in Virginia, and joins that river 22 miles below Knoxville. It is a large, bold river, upwards of 300 yards wide at that town, is about 200 miles in length, and receives in its course several considerable rivers, viz. from its head downwards, Watauga, French Broad, (which includes Limestone Creek, Nolachucky, Swanano, Big Laurel, and Big and Little Pigeon) and Little rivers. The streams on the northern side are creeks of no great size or length of course. Holston is navigable for boats of 25 tons upwards of 100 miles, as high as the mouth of the North Fork; at which place Mr David Ross has erected iron-works upon a large scale. At the mouth of this river, on the north side, stands Fort Grainger. The river is 150 yards wide, 16 miles above the North Fork at Ross's iron-works, and nearly 5 above Long-Island, and in N. lat. 36° 27′, W. long. 83° 8′.—*Morse.*

HOLSTON, a settlement on the river above mentioned, in the State of Tennessee, containing 28,649 inhabitants, though in the year 1775 it had hardly 2,200; yet its importance during the revolution may be conceived, when it is known that a great part of those volunteer troops who attacked and defeated the British and tories on King's Mountain, who were commanded by Colonel Ferguson, came from this country.

The land is generally fertile, but the face of the country is much broken. Placed between two large mountains, it seldom suffers for want of rain. It abounds with iron ore. A capital furnace and forge have lately been erected in Holston near the Virginia line, a bloomery below the mouth of Watawga, and another 25 miles above the mouth of the French Broad. There are sundry lead mines in the settlement, one in particular on the French Broad, that produces 75 per cent. pure lead. Long-Island on Holston river is 340 miles S. W. by W. of Richmond in Virginia.—*ib.*

HOLWELL (John Zephaniah, Esq;), was a gentleman of letters, whose history is well intitled to a place in such a collection as ours; but, unfortunately, we know not either the time or the place of his birth, or the school at which he was educated. At an early period of life he was sent to Bengal as a writer in the East-India Company's service, and in the year 1756, was second in council at Fort William, when an offence was given to the nabob of Bengal by the governor's protecting a fugitive native. In revenge for this, the nabob marched against the fort with a powerful army. Drake, the chief who had given the offence, deserted his station, and the command devolved on Mr Holwell, who, with the few men he had, defended the place to the last extremity. This opposition incensed the nabob against Mr Holwell; and although on the surrender he had given his word that no harm should come to him, Mr Holwell and his unfortunate fellows in arms were thrust into a close prison, called the Black Hole*, not eighteen feet square, to the number of 146 persons, and into which no supply of air could come but by two small windows in one end. Here for one whole night they were confined; the numbers crowded together caused a most profuse perspiration, which was succeeded by a raging thirst. They called for water, but the little supply which the humanity of the black soldiers could grant them, was nearly all lost in the struggle to obtain it. Every few minutes some one or other expired, through thirst, or pressure, or were trampled to death. Mr Holwell, after struggling for many hours, threw himself down on a platform, and in a short space of time happily became insensible. In this dismal dungeon they were kept till six o'clock in the morning, when twenty-three only were found alive. Mr Holwell himself was in a high fever, but was loaded with fetters and otherwise ill treated, yet the excellency of his constitution overcame all his hardships, and he was soon after released and embarked for England. In 1758 he published a well written and affecting narrative of the sufferings of himself and his companions. Since this time Mr Holwell has resided in England, and has written several tracts on Indian affairs, particularly a work in three parts, intitled "Events relative to Bengal and Hindostan."—"The manner of inoculating for the small-pox in the East Indies."—"A new experiment for the prevention of crimes," published in 1786. He has also published a tract which contains some very singular sentiments on religious subjects, intitled "Dissertations on the origin, nature, and pursuits of intelligent beings, and on Divine Providence, religion, and religious worship." Mr Holwell was elected many years ago, F. R. S. and lived to a good old age, respected by his acquaintance, and although much afflicted by bodily complaints, possessed a wonderful fund of spirits.

* See CALCUTTA, *Encycl.*

HOMER, a military township in Onondaga county, New York, on the head waters of the N. W. branch of Chenengo river; 56 of its inhabitants are electors.—*ib.*

HOMODROMUS VECTIS, or *Lever*, in mechanics, is a lever in which the weight and power are both on the same side of the fulcrum as in the lever of the 2d and 3d kind; being so called, because here the weight and power move both in the same direction, whereas in the heterodromus they move in opposite directions.

HONA CHITTO, a river which rises in Georgia, in in N. lat. 32°, between Pearl and Loofa Chitto rivers, runs foutherly 125 miles, and at the town of Manca in Weft-Florida, a few miles from its mouth, runs W. to Miffiffippi river. N. lat. 30° 25'.—*ib.*

HONDO, RIO, a river of Yucatan, which empties into the bay of Honduras. This river, by the peace of 1783, was the northern boundary of the tract fouthward of Balleffe river, granted by the Spaniards to the Britifh, to cut and carry away logwood.—*ib.*

HONDURAS, a province of New Spain, having the bay of its name and the North Sea on the north; Yucatan on the north-weft; and the Mofquito Shore on the north-eaft; Nicaragua and Guatimala on the fouth, and Vera Paz on the weft. It is about 100 leagues long and 80 broad. It abounds with honey, cotton, fine wool, dye woods in particular, and has fome gold and filver mines. The rivers overflow like the Nile, and enrich the land. The air is good, except near the lagoons and low grounds. The foil in many parts bears Indian corn thrice a year; and the vineyards bear twice a year; for immediately after the vintage they cut them again; and the fecond grapes are ripe before Chriftmas. Valladolid is the chief town, where the governor and bifhop refide. Truxillo is alfo a fine town, and very ftrong by nature; and Omoah is ftrongly fortified. The Spaniards claim this country; but the Englifh have been long in poffeffion of the logwood tract in the Bay of Honduras, cutting large quantities of it every year. And the Mofquito Indians to the eaft of this province have entered into treaties with the Englifh, received them into their country, and done them feveral fervices. Befides, the Spaniards have no forts in this bay, or in the country of the Mofquitos, only two fmall towns.—*ib.*

HONEYYOE, a lake in the Geneffee country in New-York State, weftward of Canandargua Lake, 5 miles long and 3 broad.—*ib.*

HONOMINIES, a river in the N. W. Territory which runs S. S. eafterly into Puan Bay. Between the head of this river and Lake Superior is a fhort portage.—*ib.*

HOOKE (Dr Robert) is faid, in the account of him which is publifhed in the *Encyclopædia*, to have laid claim to the inventions of others, and to have boafted of many of his own, which he never communicated. We will not prefume to fay that this charge is entirely groundlefs; but we know that it has been greatly exaggerated, and that many difcoveries undoubtedly made by him have been claimed by others. Of this the reader will find one confpicuous proof under the article Watch *(Encycl.)*; and perhaps the following hiftory of the inventions to which he laid claim may furnifh another. It would be harfh to charge him with falfity in any of them; that is to fay, to imagine that he either ftole them from others, or did not *think*, at leaft, that he was *an* inventor. And, with refpect to many of them, the priority of his claim is beyond difpute.

1656, Barometer, a weather glafs.

1657, A fcapement, for maintaining the vibration of a pendulum.—And not long after, the regulating or balance-fpring for watches.

1658, The double barrelled air pump.—The conical pendulum.—His firft employment of the conical pendulum was no lefs ingenious and fcientific than it was original. He employed it to reprefent the mutual gravitation of the planets; a fact which he had moft fyftematically announced. He had fhewn, that a force, perfectly analogous to gravity on this earth, operated on the furface of the moon and of Jupiter. Confidering the numerous round pits on the furface of the moon, furrounded with a fort of wall, and having a little eminence in the middle, as the production of volcanoes, he inferred, that the ejected matter fell back again to the moon, as fuch matter falls back again to the earth. He faw Jupiter furrounded with an atmofphere, which accompanied him; and therefore preffed on him, as our air preffes on the earth:—He inferred, that it was the fame kind of power that maintained the fun and other planets in a round form. He inferred a force to the fun from the circulation round him, and he called it a *gravitation;* and faid that it was not the earth which defcribed the ellipfe, but the centre of gravity of the earth and moon. He therefore made a conical pendulum, whofe tendency to a vertical pofition reprefented the gravitation to the fun, and which was projected at right angles to the vertical plane; and fhewed experimentally, how the different proportions of the projectile and centripetal tendencies produced various degrees of eccentricity in the orbit. He then added another pendulum, defcribing a cone round the firft, while this defcribed a cone round the vertical line, in order to fee what point between them defcribed the ellipfe. The refults of the experiment were intricate and unfatisfactory; but the thought was ingenious. He candidly acknowledged, that he had not difcovered the true law of gravitation which would produce the defcription of an ellipfe *round the focus*, owing to his want of due mathematical knowledge; and therefore left this inveftigation to his fuperiors. Sir Ifaac Newton was the happy man who made the difcovery, after having entertained the fame notions of the forces which connected the bodies of the folar fyftem, before he had any acquaintance with Dr Hooke, or knew of his fpeculations.

1660, The engine for cutting clock and watch wheels.—The chief phenomena of capillary attraction.—The freezing of water a fixed temperature.

1663, The method of fupplying air to a diving bell.—The number of vibrations made by a mufical chord.

1664, His Micrographia was, by the council of the Royal Society, ordered to be printed; but in that work are many juft notions refpecting refpiration, the compofition of the atmofphere, and the nature of light, which were afterwards attributed as difcoveries to Mayow and others, who, though we are far from fuppofing that they ftole their difcoveries from Dr Hooke, were certainly anticipated by him.

1666, A quadrant by reflection.

1667, The marine barometer.—The gage for founding unfathomable depths.

1668, The meafurement of a degree of the meridian, with a view to determine the figure of the earth, by means of a zenith fector.

1669, The fact of the *confervatio virium vivarum*, and that in all the productions and extinctions of motion, the accumulated forces were as the fquares of the final or initial velocities. This doctrine he announces in all its generality and importance, deducing from it all the confequences which John Bernoulli values himfelf fo highly upon, and which are the chief facts adduced by Leibnitz in support of his doctrine of the forces of bodies in motion. But Hooke was perfectly aware of their entire correspondence with the Cartesian, or common doctrine, and was one of the first in applying the celebrated 39th proposition of Newton's Principia to his former positions on this subject, as a mathematical demonstration of them.

1673, That the catenarea was the best form of an arch.

1674, Steam engine on Newcomen's principle.

1679, That the air was the sole source of heat in burning: That combustion is the solution of the inflammable vapour in air; and that in this solution the air gives out its heat and light. That nitre explodes and causes bodies to burn without air, because it consists of this air, accompanied by its heat and light in a condensed or solid state; and air supports flame, because it contains the same ingredients that gunpowder doth, that is, a nitrous spirit: That this air dissolves something in the blood while it is exposed to it in the lungs in a very expanded surface, and when saturated with it, can no longer support life nor flame; but in the act of solution, it produces animal heat: That the arterial and venal blood differ on account of this something being wanting in one of them. In short, the fundamental doctrines of modern chemistry are systematically delivered by Dr Hooke in his Micrographia, published in 1664, and his Lampas, published in 1677.

1680, He first observed the secondary vibrations of elastic bodies, and their connection with harmonic sounds. A glass containing water, and excited by a fiddlestick, threw the water into undulations, which were square, hexagonal, octagonal, &c. shewing that it made vibrations subordinate to the total vibration; and that the fundamental sound was accompanied by its octave, its twelfth, &c.

1681, He exhibited musical tones by means of toothed wheels, whirled round and rubbed with a quill, which dropped from tooth to tooth, and produced tones proportioned to the frequency of the cracks or snaps.

1684, He read a paper before the Royal Society, in which he affirms, that some years before that period he had proposed a method of discoursing at a distance, not by sound, but by sight. He then proceeds to describe a very accurate and complete telegraph, equal, perhaps, in all respects to those now in use. But some years previous to 1684, M. Amontans had not invented his telegraph; so that, though the Marquis of Worcester unquestionably gave the first hint of this instrument, Dr Hooke appears to have first brought it to perfection. See TELEGRAPH, *Encycl.*; and a book, published 1726, entitled *Philosophical Experiments and Observations* of the late eminent Dr Robert Hooke.

We are indebted to him for many other discoveries of lesser note; such as the wheel barometer, the universal joint, the manometer, screw divided quadrant, telescopic sights for astronomical instruments, representation of a muscular fibre by a chain of bladders, experiments shewing the inflection of light, and its attraction for solid bodies, the curvilineal path of light through the atmosphere.

HOOKSET FALLS, or *Hookset Isle Falls* in Merrimack river, just below the mouth of Suncook, 7 miles above Amuskeag Falls, and 8 miles below Concord, in New-Hampshire.—*Morse*.

HOOKSTOWN, a village on the west side of Chesapeak Bay in Maryland, in Baltimore county, 6 miles N. W. of the town of Baltimore.—*ib.*

HOOKTOWN, a village on the east side of Chesapeak Bay, in Talbot county, Maryland, lies north of Easton, and S. W. of Williamsburg, nearly 3 miles from each.—*ib.*

HOOPER'S ISLAND AND STRAITS lie on the east side of Chesapeak Bay, and on the S. W. coast of Dorchester county, Maryland. The island is 7 miles long, and 2½ broad.—*ib.*

HOOSACK, a river of New-York which falls into the Hudson from the east, about 8 miles above the city of Lansinburgh. It rises in Berkshire county, Massachusetts, runs north-westerly through Pownal in Vermont, thence into New-York State. Its length is about 40 miles. The curious mill-stream called Hudson's Brook, which falls into a north branch of Hoosack, is described in the article *Adams*, in this *Supplement*.—*ib.*

HOPE, a village in Sussex county, New-Jersey, on the post-road from Newtown to Easton in Pennsylvania, 16 miles S. W. of the former, and 20 N. E. of the latter. It is inhabited by about 100 of the Moravian United Brethren.—*ib.*

HOPE, a bay on the N. W. coast of N. America, so named by Capt. Cook. The entrance of Nootka, or St George's Sound, is situated in the east corner of Hope Bay, in N. lat. 49° 33′, E. long. 233° 12′.—*ib.*

HOPE, a Moravian settlement in Wachovia, in N. Carolina, in Surry county, where is a meeting-house of the United Brethren.—*ib.*

HOPE, a small island in Narraganset Bay, State of Rhode-Island.—*ib.*

HOPEWELL, a township in Cumberland county, in the province of New-Brunswick, situated on Chepodie river, which runs easterly into a northern arm of the Bay of Fundy, and is navigable 4 or 5 miles.—*ib.*

HOPEWELL, the name of 3 townships in Pennsylvania, viz. in York, Huntingdon, and Washington counties.—*ib.*

HOPEWELL, a township in Hunterdon county, New-Jersey, situated on Delaware river, 14 miles W. of Princeton, 11 above Trenton and 30 south-westerly of New-Brunswick. It contains 2320 inhabitants, including 233 slaves. Another township of this name lies in Cumberland county, in New-Jersey.—*ib.*

HOPKINS, or *Hopkinsville*, a township in Caledonia county, in Vermont, was granted to Dr Hopkins; 11 miles northwest of the upper bar of the Fifteen Mile Falls in Connecticut river.—*ib.*

HOPKINSON (Francis, Esq.) Judge of the Court of Admiralty in Pennsylvania, possessed an uncommon share of genius of a peculiar kind. He excelled in music and poetry, (A) and had some knowledge

(A) He invented an improved tongue for the harpsichord; a description of which accompanied with an engraving, may be seen in the Columbian Magazine for May 1787. He also published a small collection of songs, composed and set to musick by himself, which have been universally admired.

ledge in painting. But these arts did not monopolise all the powers of his mind. He was well skilled in many practical and useful sciences, particularly mathematics and natural philosophy, and he had a general acquaintance with the principles of anatomy, chemistry, and natural history.—But his *forte* was *humour* and *satire*, in both of which he was not surpassed by Lucian, Swift, or Rabelais. These extraordinary powers were consecrated to the advancement of the interests of patriotism, virtue, and science. It would fill many pages to mention his numerous publications during the late revolution, all of which were directed to those important objects.——He began in the year 1775, with a small tract which he entitled "A pretty story" in which he exposed the tyranny of Great Britain in America, by a most beautiful allegory, and he concluded his contributions to his country, in this way, with the history of "a new roof." A performance, which for wit, humour, and good sense, must last as long as the citizens of America continue to admire, and to be happy under, the present national government of the United States.

Newspaper scandal, frequently for months together, disappeared or languished, after the publication of several of his irresistible satires upon that disgraceful species of writing. He gave a currency to a *thought* or *phrase* in these effusions from his pen, which never failed to bear down the spirit of the times, and frequently to turn the divided tides of party-rage, into one general channel of ridicule or contempt.

Sometimes he employed his formidable powers of humour and satire in exposing the formalities of technical science.—He thought much, and thought justly, upon the subject of education. He often ridiculed in conversation, the practice of teaching children the English language by means of grammar. He considered most of the years which are spent in learning the Latin and Greek languages as lost, and he held several of the arts and sciences which are still taught in our colleges, in great contempt. His specimen of modern learning, in a tedious examination, the only object of which was to describe the properties of a "salt-box," published in the American Museum for February 1787, will always be relished as a morsel of exquisite humour, while the present absurd modes of education continue to be practised in the United States.

Mr Hopkinson possessed uncommon talents for pleasing in company. His wit was not of that coarse kind which was calculated to "set the table in a roar." It was mild and elegant, and infused cheerfulness, and a species of delicate joy, rather than mirth, into the hearts of all who heard it. His empire over the attention and passions of his company was not purchased at the expense of innocence. A person who has passed many delightful hours in his society, declares with pleasure, that he never once heard him use a profane expression, nor utter a word that would have made a lady blush, or have clouded her countenance for a moment with a look of disapprobation. It is this species of wit alone that indicates a rich and powerful imagination, while that which is tinctured with profanity, or indelicacy, argues poverty of genius, inasmuch as they have both been considered very properly, as the cheapest products of the mind.

Mr Hopkinson's character for abilities and patriotism procured him the confidence of his countrymen in the most trying exigencies of their affairs. He represented the state of New-Jersey, in Congress, in the year 1776, and subscribed the ever-memorable declaration of independence. He held an appointment in the loan-office for several years, and afterwards succeeded George Ross, Esq. as judge of the admiralty for the state of Pennsylvania. In this station he continued till the year 1790, when he was appointed judge of the district court in Pennsylvania, by the President of the United States. In each of these judicial offices, he conducted himself with integrity. His education qualified him for their duties, for he had been regularly bred to the law, under Benjamin Chew, Esq. when attorney general of Pennsylvania.

He was an active and useful member of three great parties which at different times divided his native state —he was a *whig*, a *republican*, and a *federalist*, and he lived to see the principles and wishes of each of those parties finally and universally successful. Although his labours had been rewarded with many plentiful harvests of well-earned fame, yet his death, to his country and his friends, was premature. He had been subject to frequent attacks of the gout in his head, but for some time before his death, he had enjoyed a considerable respite from them. On Sunday evening, May the 8th, 1791 he was somewhat indisposed, and passed a restless night after he went to bed. He rose on Monday morning at his usual hour, and breakfasted with his family.—At seven o'clock he was seized with an apoplectic fit, which in two hours put a period to his existence, in the 53d year of his age.

His person was a little below the common size. His features were small, but extremely animated. His speech was quick, and all his motions seemed to partake of the unceasing activity and versatility of the powers of his mind.

It only remains to add to this account of Mr Hopkinson, that the various causes which contributed to the establishment of the independence and federal government of the United States, will not be *fully traced*, unless much is ascribed to the irresistible influence of the *ridicule* which he poured forth, from time to time, upon the enemies of those great political events.

HOPKINTON, a township in Hillsborough county, New-Hampshire, on Contoocook river, 9 miles S. W. from its confluence with the Merrimack, and divided from Concord on the east, by the Rockingham county line. It was first granted by Massachusetts, was incorporated in 1765, and contains 1,715 inhabitants, who are chiefly farmers. It is 42 miles E. by S. of Charlestown on Connecticut river, and about 58 W. by N. of Portsmouth.—*Morse.*

HOPKINTON, a township in Middlesex county, Massachusetts. It was incorporated in 1715, and contains 1317 inhabitants. The rivers Concord, Providence and Charles receive each of them a branch from this town: These streams furnish seats for 7 or 8 grist-mills, a number of saw-mills, iron-works, &c.—*ib.*

HOPKINTON, a township in Washington county, Rhode-Island, situated on the west line of the State, on several branches of Pawcatuck river. It contains 2462 inhabitants, including 7 slaves.—*ib.*

HORNE (George, D. D.), late Lord Bishop of Norwich, was a man of such amiable dispositions, primitive

Horne.

mitive piety, and exemplary morals, that we wish it were in our power to do justice to his character. His life, it is true, has been already written, at considerable length, by two authors, possessed of erudition and of unquestionable integrity; but mere erudition is by no means sufficient to fit a man for discharging the duties of a biographer. It was not the learning of Johnson, but his sagacity, and intimate acquaintance with human nature, that placed him so far above his contemporaries in this department of literature.

Of Bishop Horne's biographers, one possessed, indeed, the great advantage of having lived in habits of intimacy with him from his boyish years. In the authenticity of his narrative, therefore, the fullest confidence may be placed: and that narrative we shall faithfully follow; reserving, however, to ourselves the liberty of sometimes making reflections on the various incidents recorded, widely different from those of the author.

George Horne was, in 1730, born at Otham in Kent, a village near Maidstone, giving the name to a parish, of which his father was the rector. He was the second of four sons; of whom the eldest died in very early life, and the youngest, who is still alive, succeeded his father both in the rectory of Otham and in that of Breda in the county of Sussex. He had likewise three sisters, of whose fortunes we know nothing.

Mr Horne, the father of the family, was of a temper so remarkably averse from giving pain or trouble upon any occasion, that he used to awake his son George, when an infant, by playing upon a flute, that the change from sleeping to awaking might be gradual and pleasant. Having been for some years a tutor at Oxford, he took upon himself the early part of the classical education of his favourite son; an office of which he was well qualified to discharge the duties. Under such an instructor, the subject of this memoir led a very pleasant life, and made a rapid progress in the Greek and Latin languages. By the persuasion of a friend, however, he was, at the age of thirteen, placed in the school of Maidstone, then under the care of a Mr Bye, eminent for his knowledge of ancient literature. And remaining with this gentleman two years, he added much to his stock of learning; and, among other things, a little elementary knowledge of the Hebrew tongue, which Mr Bye taught on the plan of Buxtorf. Though Dr Horne afterwards rejected that plan, he readily admitted, that the knowledge of it was of great advantage to him.

At the age of fifteen, he was removed from Maidstone school to University college Oxford, where his father had happily obtained for him a scholarship. At college his studies were, in general, the same with those of other virtuous and ingenious youths; while the vivacity of his conversation, and the propriety of his conduct, endeared him to all whose regard was creditable. About the time of his taking his batchelor's degree, he was chosen a fellow of Magdalen College; and soon afterwards, if not before, commenced author.

The history of his authorship is curious, and we shall give it at some length. While he was deeply engaged in the study of oratory, poetry, and every branch of polite literature, he was initiated by his faithful friend Mr Jones in the mysteries of Hutchinsonianism; but Mr Jones was not his preceptor. Indeed that gentleman informs us, that when he first communicated to Mr Horne the novelties with which his own mind was filled, he found his friend very little inclined to consider them; and had the mortification to see, that he was himself losing ground in Mr Horne's esteem, even for making the attempt to convert him. At this we are not to be much surprised. Mr Horne, though, by his biographer's account, no deep Newtonian, saw, or thought he saw, the necessity of a *vacuum* to the possibility of *motion;* and as we believe that every man, who knows the meaning of the words *motion* and *vacuum*, and whose mind is not biassed in favour of a system, sees the same thing, it was not to be supposed, that a youth of sound judgment would hastily relinquish so natural a notion. By Mr Horne, however, it was at length relinquished. Mr Jones introduced him to Mr George Watson, a fellow of University college, whom he represents as a man of very superior accomplishments; and by Mr Watson Mr Horne was made a Hutchinsonian of such zeal, that at the age of nineteen he implicitly adopted the wild opinion of the author of that system, that Newton and Clarke had formed the design of bringing the Heathen *Jupiter*, or Stoical *anima mundi*, into the place of the God of the universe. With such a conviction impressed upon his mind, it is not wonderful that he should endeavour to discredit the system of Newton. This he attempted, by publishing a parallel between that system and the Heathen doctrines in the *Somnium Scipionis* of Cicero. That publication which was anonymous, we have never seen; but Mr Jones himself admits it to have been exceptionable; and the amiable author seems to have been of the same opinion, for he never republished it, nor, we believe, replied to the answers which it provoked.

He did not, however, desert the cause, but published, soon afterwards, a mild and serious pamphlet, which he called *A Fair, Candid, and Impartial State of the Case between Sir Isaac Newton and Mr Hutchinson*. Even of this pamphlet we have not been able to procure a sight; but Mr Jones assures us, that the author allows to Sir Isaac the great merit of having settled laws and rules in natural philosophy, and of having measured *forces* as a mathematician with sovereign skill; whilst he claims for Mr Hutchinson the discovery of the true physiological causes, by which, under the power of the Creator, the natural world is moved and directed.

If this be a fair view of *the state of the case*, it allows to Newton more than ever Newton claimed, or has been claimed for him by his fondest admirers; for the laws and rules, which he so faithfully followed in the study of philosophy, were not settled by him, but by the illustrious Bacon. With respect to the *true* causes here mentioned, we have repeatedly had occasion, during the course of this Work, to declare our opinion, that all men are equally ignorant of them, if they be considered as any thing distinct from the general *laws* by which the operations of nature are carried on. To the discovery of other physiological causes, Newton, in his greatest work, made indeed no pretension; but it may be worth while, and can hardly be considered as a digression, to consider what are the pretensions of Hutchinson, to which Messrs Horne and Jones gave so decided a preference.

Mr Hutchinson himself writes so obscurely, that we dare

Horne.

dare not venture to translate his language into common English, lest we should undesignedly misrepresent his meaning; but according to Mr Jones, who has studied his works with care, his distinguishing doctrine in philosophy is, that "The forces, of which the Newtonians treat, are not the forces of nature; but that the world is carried on by the action of the elements on one another, and all under God." What is here meant by the elements, we are taught by another eminent disciple of that school. "The great agents in nature, which carry on all its operations, are certainly (says Mr Parkhurst) the *fluid* of the heavens; or, in other words, the fire at the orb of the sun, the light issuing from it, and the spirit or gross air constantly supporting, and concurring to the actions of the other two." (See CHERUBIM in this *Supplement*). Mr Horne adopted this system in preference to the Newtonian; because, says his biographer, "It appeared to him nothing better than raving, to give active powers to matter, supposing it capable of acting where it is not; and to affirm, at the same time, that all matter is inert, that is, inactive; and that the *Deity* cannot act but where he is *present*, because his *power* cannot be but where his *substance* is."

That much impious arrogance has been betrayed, not by Newtonians only, but by philosophers of every school, when treating of the *modus operandi* of the Deity, we feel not ourselves inclined to controvert; but we never knew a well-informed Newtonian, who spoke of the active powers of matter but in a metaphorical sense; and such language is used, and must be used, by the followers of Hutchinson. Mr Jones speaks of the *action* of the elements; and Mr Parkhurst calls the fluid of the heavens, which, according to him, consists of fire, light, and air, *agents;* but it would surely be uncandid to accuse these two pious men of *animating* the elements, though we know that *action* and *activity*, in the literal sense of the words, can be predicated only of living beings. With respect to giving active powers to matter, therefore, the followers of Hutchinson rave just as much as those of Newton; and we see not the raving of either in any other light than as the necessary consequence of the poverty of language.

But the Newtonian makes matter act upon matter at a distance! No; the genuine Newtonian does not make matter *act* (in the proper sense of the word) at all; but he believes, that God has so constituted matter, that the motions of different masses of it are affected by each other at a distance: and the Hutchinsonian holds the very same thing. As this celestial fluid of Mr Parkhurst's consists partly of air, we know, by the test of experiment, that it is elastic. The particles of which it is composed are therefore distant from each other; and yet they resist compression. How does the Hutchinsonian account for this fact? Perhaps he will say, that as matter is in itself equally indifferent to motion and rest, God has so constituted the particles of this fluid, that though they possess no innate power or activity of their own, they are affected by each other at a distance, in consequence of his fiat at the creation. This we believe to be the only solution of the difficulty which can be given by man; but it is the very answer given by the Newtonians to those who object to them the absurdity of supposing matter to be affected by matter at a distance. That the motions of the heavenly bodies are affected by the presence of each other is a fact, say they, which appears incontrovertible. "We have ascertained with precision the laws by which these motions are regulated: and without troubling ourselves with the true physiological causes, have demonstrated the agreement of the phenomena with the laws. The interposition of this celestial fluid removes not a single difficulty with which our doctrine is supposed to be clogged. To have recourse to it can therefore serve no purpose, even were the phenomena consistent with the nature of an elastic fluid considered as a physical cause; but this is not the case. It is demonstrable (see ASTRONOMY and DYNAMICS in this *Suppl.*), that the motions of the heavenly bodies are not consistent with the mechanism of an elastic fluid, considered as the cause of these motions; and therefore, whether there be such a fluid or not diffused through the solar system, we cannot allow that it is the great agent in nature by which all its operations are carried on."

Such might be the reasoning of a well-informed Newtonian in this controversy; and it appears so conclusive against the objections of Hutchinson to the Newtonian forces, as well as against the agents which he has substituted in their stead, that some of our readers may be disposed to call in question the soundness of that man's understanding who could become a Hutchinsonian so zealous as Mr Horne. But to these gentlemen we beg leave to reply, that the soundest and most upright mind is not proof against the influence of a system, especially if that system has novelty to recommend it, and at the same time consists of parts, of which, when taken separately, many are valuable. Such was the system of Hutchinson when adopted by Mr Horne. It was then but very little known; it could be studied only through the medium of Hebrew literature, not generally cultivated; and that literature, to the cultivation of which Mr Hutchinson had given a new and a better turn, is in itself of the utmost importance. Let it be observed, too, that the Hutchinsonians have, for the most part, been men of devout minds, zealous in the cause of Christianity, and untainted by a variety of extravagant heresies which have so often divided the church of Christ:—and when all these circumstances are taken into consideration, it will not be deemed a proof of any defect in Mr Horne's understanding, that in early life he adopted the *whole* of a system, of which some of the parts contain so much that is good; especially when it is remembered, that at *first view* the agency of the celestial fluid appears so plausible, that for a time it seems to have imposed upon the mind of Newton himself.

But the truth is, that Mr Horne was at no period of his life a thorough paced Hutchinsonian. It is confessed by Mr Jones, that "Mr Hutchinson and his admirers laid too great a stress on the evidence of Hebrew etymology; and that some of them carried the matter so far as to adopt a mode of speaking, which had a nearer resemblance to cant and jargon than to sound sense and sober learning. Of this (continues he) Mr Horne was very soon aware; and he was in so little danger of following the example, that he used to display the foibles of such persons with that mirth and good humour," which he possessed in a more exquisite degree than most men. This seems to be complete evidence that he was never a friend to the etymological

cal part of the system; and the present writer can attest, that, in the year 1786, he seemed by his conversation to have lost much of his conviction of the agency of the celestial fluid. He continued, indeed, to study the Hebrew Scriptures on the plan of Mr Hutchinson, unincumbered with the Masoretic points, or with rabbinical interpretations; and the fruits of his studies are in the hands of the religious public, in works which, by *that* public, will be esteemed as long as their language is understood.

Hitherto Mr Horne was a layman, but he interested himself in every thing connected with religion, as much as the most zealous dignitary of the church; and considering the *naturalization* of the Jews as a measure at least indecent in a Christian country, he published, in an evening paper, a series of letters on that subject, both when the Jew-bill was depending, and after it had passed the house. The letters were anonymous; but they attracted much notice, and many groundless conjectures were made respecting their author. To the real author, the measure which they opposed was so very obnoxious, that he refused to dine at the table of a friend, only because the son-in-law of Mr Pelham was to be there. And he was not much more friendly to the marriage-act than to the Jew-bill. If he considered the one as disgraceful to religion, he probably thought that the other, with its numerous clauses, might be made a snare for virtue.

The time now approached when he was to take holy orders, which to him was a very serious affair; and when he gave an account of his ordination to an intimate friend, he concluded the letter with the following reflections, which, even in an abstract like this, it would be unpardonable to omit:

"May he, who ordered Peter three times to *feed his lambs*, give me grace, knowledge, and skill, to watch and attend to the flock which he purchased upon the cross, and to give rest to those who are under the burden of sin and sorrow. It hath pleased God to call me to the ministry in very troublesome times indeed, when a lion and a bear have broken into the fold, and are making havoc among the sheep. With a firm, though humble confidence, do I purpose to go forth; not in my own strength, but in the strength of the Lord God; and may he prosper the work of my hands!" This was in the year 1753, when the pious author was hardly 23 years of age; and he had not been many months in orders, when one of the most celebrated preachers in the metropolis pronounced, that "George Horne was, without exception, the best preacher in England."

In the year 1756, he was again involved in controversy. A pamphlet had been published at Oxford, supposed by Mr Kennicott, who afterwards gained such fame as a collator of Hebrew manuscripts, entitled *A Word to the Hutchinsonians*, in which Mr Horne was personally struck at. To this work our author replied in a small tract, called *An Apology for certain Gentlemen in the University of Oxford, Aspersed in a late Anonymous Pamphlet*; and whatever may be thought of the question at issue, all men must admire the temper with which the apologist conducted himself under very great provocation.

But it was not about Hutchinsonianism alone that these two illustrious men were doomed to differ. Mr Horne took a decided part against Mr Kennicott's proposal for collating the text of the Hebrew bible, with such manuscripts as could be found, for the purpose of *reforming the text*, and preparing it for a new translation into the English language; and in the year 1760, he published *A View of Mr Kennicott's Method of Correcting the Hebrew Text, with three Queries formed thereon, and humbly submitted to the Christian world.* That his alarm was on this occasion too great, experience has shewn; but that it was not groundless, is evident from the *View*, in which the reader will find above 20 instances from Mr Kennicott's dissertations (see KENNICOTT, *Encycl.*), to shew what an inundation of licentious criticism was breaking in upon the sacred text. Indeed there is reason to believe, that this tract, together with another on the same side of the question by Dr Rutherforth of Cambridge, contributed to repress the collator's rashness, and to make the Bible of Dr Kennicott the valuable work which we find it. Be this as it may, such was the moderation of the Drs Kennicott and Horne, that though their acquaintance commenced in hostility, they at length contracted for each other a friendship, which lasted to the end of their lives, and still subsists between their families.

In what year Mr Horne was admitted to the degree of D. D. and when he was chosen president of his college, Mr Jones has not informed us; but, if our memory does not deceive us, he had obtained both these preferments when, in the year 1772, he gave to the public a small work, 8vo, intitled *Considerations on the Life and Death of St John the Baptist.* This tract was the substance of a course of sermons, which he had many years before, in conformity to an established custom at Magdalen College, preached before the university of Oxford. Mr Jones, speaking of it, says, that "he is persuaded, there was no other man of his time, whose fancy as a writer was bright enough, whose skill as an interpreter was deep enough, and whose heart as a moralist was *pure* enough, to have made him the author of that little work." By most readers this strain of panegyric will be thought extravagant, and of course it will defeat its own purpose; but the work is certainly a work of merit.

In the year 1776, when the author was vice-chancellor, was published, in two volumes 4to, Dr Horne's Commentary on the Psalms. It is a work of which very different opinions have been formed, though it was the result of the labour of twenty years. That it will always be a favourite companion of the devout Christian, we are as much inclined to believe as Mr Jones; but we cannot, without belying our own judgment, say that it appears to us calculated to produce much general good in an age like the present. Granting it to be true, which we believe will not be granted without some exceptions, that Clarke, and Hoadley, and Hare, and Middleton, and Warburton, and SHERLOCK, and SOUTH, and WILLIAM LAW, and Edmund Law, had turned the public attention, of which they had got the entire command, too much to the *letter* of the bible to the neglect of the *spirit* of it; should not Dr Horne, after the example of St Paul, have let in the light gradually upon such weak organs as those of the public thus diseased, rather than pour it upon them at once in a flood of splendor. The apostle "fed his Corinthian converts with milk and not with

Horne.

with meat," when he found them unable to bear the latter food; and there is reason to suspect that the carnal followers of Warburton, and Sherlock, and South, were unable to bear, at once, such strong meat, as that which makes the fifteenth psalm a portrait of our Saviour. Indeed, we think it not improbable that the mind of Sherlock would have recoiled with horror from the very conception of the *possibility* of Jesus Christ "swearing to his neighbour and disappointing him," though that conception must have passed through a mind which was certainly as pure as his. The commentary, however, though truth thus compels us to say that, in our opinion, it is far from perfect, is certainly a work of great learning, great genius, and fervent piety, and such as the devout Christian will peruse again and again with much advantage.

Dr Horne's next work was of a different kind, and, we think, of a superior order. In the year 1776 was published a letter of Dr Adam Smith's, giving an account of the death of Mr David Hume. The object of the author was to shew that Mr Hume, notwithstanding his sceptical principles, had died with the utmost composure, and that in his life as well as at his death he had conducted himself as became one of the wisest and best men that ever existed. The letter is very much laboured, and yet does no honour either to the author or his friend. It could not represent Mr Hume as supporting himself under the gradual decay of Nature with the hopes of a happy immortality; but it might have represented him as taking refuge, with other infidels, in the eternal sleep of death. This, though but a gloomy prospect, would not have been childish; but the hero of the tale is exhibited as talking like a school boy of his conferences with Charon, and his reluctance to go into the Stygian ferry-boat, and consoling himself with the thought of leaving all his friends, and his brother's family in particular, in great prosperity!!! The absurdities of this letter did not escape the watchful and penetrating eye of Dr Horne; and as he could not mistake its object, he held it up to the contempt and scorn of the religious world in *A Letter to Adam Smith, L. L. D. on the Life, Death and Philosophy of his Friend David Hume, Esq; by one of the People called Christians.* The reasoning of this little tract is clear and conclusive, while its keen, though good humoured wit is inimitable; and it was, some years afterwards, followed by a series of *Letters on Infidelity*, composed on the same plan, and with much of the same spirit. This small volume, to the second edition of which the letter to Dr Smith was prefixed, is better calculated, than almost any other with which we are acquainted, to guard the minds of youth against the insidious strokes of infidel ridicule, the only dangerous weapon which infidelity has to wield.

When the letters on infidelity were published, their author had for some time been Dean of Canterbury, where he was beloved by the chapter and almost adored by the citizens. He was a very frequent preacher in the cathedral and metropolitical church, where the writer of this short sketch has listened to him with delight, and seen thousands of people of very various descriptions hang with rapture on his lips. As a preacher indeed he excelled; and notwithstanding the shortness of his sight, which deprived him of some of the graces of a pulpit orator, such were the excellence of his matter, the simple elegance of his style, and the sweetness of his voice, that, when at the primary visitation of the present archbishop, he preached his admirable sermon *on the Duty of Contending for the Faith*, the attention of more than 2000 people was so completely fixed, that the smallest noise was not to be heard through the whole crowded choir. Of the importance of preaching, and of the proper mode of performing that duty, he had very just notions; and though he never had himself a parochial cure of souls, it was the desire and pleasure of his life to make himself useful in the pulpit wherever he was, whether in town or in the most obscure corner of the country. Four or five volumes of his sermons have been published since his death.

In the year 1787 he published, under the name of an undergraduate of the university of Oxford, *a letter to Dr Priestley*, in which he made that oracle of Socinianism almost as ridiculous as, in the letter to Dr Smith, he had formerly made the hero of modern scepticism.

The merits of Dr Horne, which had made him president of Magdalen College, a king's chaplain, and dean of Canterbury, raised him, we think in the year 1790, to the see of Norwich; and he had soon an opportunity of shewing that he had not lost sight of his spiritual character in the splendor of the peer of parliament. The Scotch Episcopalians had for some time been soliciting the legislature to repeal certain penal laws of uncommon severity, under which they had groaned for upwards of forty years; but they found it a work of no little difficulty to make the equity of their claim generally understood*. In removing this difficulty no man was more assisting to them than the Dean of Canterbury, to whom their religious and political principles were well known; and he continued his assistance after he was bishop of Norwich. Indeed the whole bench shewed, on this occasion, a zeal for the interests of true religion every way becoming their character of Christian bishops; and after Dr Horne was removed to a better world, the Scotch Episcopalians found among his surviving brethren friends as zealous and active as he.

* See Scotch Episcopalians in this *Supplement*.

Dr Horne, though a very handsome man, was not naturally of a strong constitution; and from the disadvantage of being uncommonly near sighted, he had not been able to increase its strength by the practice of any athletic exercise. The only amusement in which he took delight was agreeable conversation; and his life was therefore what is called sedentary. The consequence of this was, that the infirmities of age came fast upon him; and when the design was formed of making him a bishop, he felt himself little inclined to undertake the charge of so weighty an office. He was, however, prevailed upon to accept of the see of Norwich; but he enjoyed his new dignity for a very short period, if he can with truth be said to have *enjoyed* it at all. His health declined rapidly; and, in the autumn of 1791, he suffered, while on the road from Norwich to Bath, a paralytic stroke, the effects of which he never recovered. He lingered a month or two, with such apparent changes in the state of his health as sometimes gave delusive hopes to his family, till the 17th of January 1792, when he died in the 62d year of his age, with those hopes which can be excited only by the consciousness of a well spent life, and by a firm trust in the promises of the gospel.

In this short sketch of the life of bishop Horne we have taken the liberty to express our dissent from some of his opinions, and to state the reasons on which that dissent rests. By himself we know that this part of our conduct would have been applauded; but it is possible that by some of his friends it may be deemed disrespectful to his memory. To these gentlemen we beg leave to observe, that if Johnson made the praise of *Kyrl*, Pope's man of Ross, really more solid by making it more credible, it will be difficult to persuade us that we have done any injury to Dr Horne's fame by avoiding the extravagant panegyric of those who seem to have considered him as a man exempted from error. He was first induced to favour the Hutchinsonians because he thought he perceived danger to religion in the Newtonian doctrines of attraction and repulsion; and we very readily admit that many Newtonians, not understanding the doctrines of their master, have expressed themselves in such a manner as could not render a religious man partial to their system. But from the dangers of mistake no system, whether religious or philosophical, was ever free; and the atheistical purposes which the agency of ethers and celestial fluids has lately been made to serve, must induce every man of piety to pause before he admit such agency. Dr Horne lived to witness some of its pernicious effects; and we have reason to believe that they made a due impression on his mind; but he spent his latter years, as indeed he had spent the greater part of his life, in nobler pursuits than the study of human science; he spent them in the proper employments of a Christian, a clergyman, and a bishop. His faith was founded on a rock; and it was that genuine faith which worketh by love; for though his preferments were rich, his charity kept pace with them; and it has been proved that, notwithstanding his proper economy, he hoarded not one shilling of his annual income. This was an elevation of character above all literary, above all philosophic fame. The author of this article had the honour to be known to Dr Horne, to enjoy, if he mistook not, a share in his friendship, and to correspond with him regularly for many years; and there is not one of his rational admirers who more fully admits the truth of the character given of him by Dr Thurlow late bishop of Durham when succeeding him in the office of proctor in the University. "As to the last proctor (said he) I shall speak of him but in few words, for the truth of which I can appeal to all that are here present. If ever virtue itself was visible and dwelt upon earth, it was in the person who this day lays down his office."

Soon after he was advanced to the presidentship of Magdalen college, this great and good man married the only daughter of Philip Burton, Esq; a gentleman of considerable fortune. By this lady he had three daughters, of whom the eldest was married to a clergyman a short time before the death of her father, and the two younger were, in 1796, residing with Mrs Horne in Hertfordshire.

HORN-TOWN, a village in Maryland, 31 miles from Snowhill, 26 from Drummond, or Accomack court-house, in Virginia, and 168 from Philadelphia. —*Morse*.

HOROGRAPHY, the art of making or constructing dials; called also dialling, horologiography, gnomonica, sciatherica, photosciatherica, &c.

HOROPTER, in optics, is a right line drawn through the point where the two optic axes meet, parallel to that which joins the centres of the two eyes, or the two pupils.

HORSENECK-FIELD-POINT, a round bluff on the coast of Greenwich township in Connecticut, 2 miles E. of the New-York line at Byram river.—*Morse*.

Horseneck, a point of land, on the north side of Long-Island, between Hog's Neck and Easton's Neck. —*ib*.

Horseneck, a town in Fairfield county, Connecticut, called by the Indians *Pai hom sing*, was settled in 1680. It lies six miles N. E. of Rye, in West-Chester county, New-York State. A bloody battle was fought here between the Dutch and the Indians, in 1646. The Dutch with great difficulty gained the victory. Great numbers were slain on both sides; and their graves appear to this day. It is 53 miles S. W. of New-Haven, and 37 N. E. of New-York city.—*ib*.

Horseneck, a village in Essex county, New-Jersey, on the southern bank of Passaic river above the Little Falls, four miles S. W. by S. of the town of Patterson.—*ib*

HORSE-Shoe, in fortification, is a work sometimes of a round, sometimes of an oval figure, inclosed with a parapet, raised in the ditch of a marshy place, or in low grounds; sometimes also to cover a gate; or to serve as a lodgment for soldiers, to prevent surprises, or relieve an over tedious defence.

HORSHAM, a township in Montgomery county, Pennsylvania.—*Morse*.

HOSACK, or *Hoosack*, a township in Renssalaer county, New-York, situated on the eastern boundary of the State, contains 3035 inhabitants, 419 of whom are electors.—*ib*.

HOVEN is a word of the same import with *raised, swelled, tumefied*. It is particularly applied to black cattle and sheep, when from eating too voraciously of clover, or any other succulent food, they become swollen. Such cattle are, in the language of the farmer, called, *Hoven-Cattle*; and the beast, whether bullock or sheep, which is hoven, when left without relief, dies in half an hour. The cause of the disease is the extra-quantity of air taken down with that kind of food, which, in its passage from the paunch upwards, forces the broad leaves of the clover before it, till they close up the passage at the entrance of the paunch, and prevent the wind from going upwards in its regular course. The usual method of relief is to stab the animal in the paunch; an operation which is always dangerous, and has often proved fatal. It was therefore with good reason that the Society for the Encouragement of Arts, Manufactures, and Commerce, voted a bounty of fifty guineas to Mr Richard Eager of Graffham farm, near Guildford, for making public a very simple method practised by him for the cure of hoven cattle. It is this; "let the grazier or farmer have always ready smooth knobs of wood, of different sizes, fixed to the end of a flexible cane, which for oxen should be at least six feet long, and for sheep three feet. When a beast is hoven, let one person take hold of him by the nostril and one horn; let another hold his tongue fast in one hand, putting the cane down his throat with the other. Be careful not to let the animal get the knob of the cane between his grinders: observe also to put the cane far enough

enough down; the whole length will not injure. You will find the obſtacle at the entrance of the paunch: puſh the cane hard, and when you perceive a ſmell to come from the paunch, and the animal's body to ſink, the cure is performed, and Nature will act for itſelf."

This method, we doubt not, will prove ſucceſsful; but might not the purpoſe be as well, if not better, effected, by uſing, inſtead of the cane and knob, a piece of thick ſtiff rope, which, in many places of Scotland, is employed to force down turnips or potatoes when they ſtick in the throat of a bullock?

HOUGHTON (——) is a man to whom the ſcience of geography is ſo much indebted, that we are almoſt aſhamed to confeſs that we know not his Chriſtian name, the place where he was born, or the age at which he died. He had been a captain in the 69th regiment, and in the year 1779 had acted under General Rooke as fort major in the iſland of Goree. Hearing, ſome time in the year 1789, or perhaps earlier, that the African aſſociation wiſhed to penetrate to the Niger by the way of Gambia, he expreſſed his willingneſs to undertake the execution of their plan. For this taſk he was peculiarly fitted. A natural intrepidity of character, which ſeemed inacceſſible to fear, and an eaſy flow of conſtitutional good humour, which even the roughest accidents of life were not able to ſubdue, formed him for exploring the country of relentleſs ſavages; whilſt the darkneſs of his complexion was ſuch, that he ſcarcely differed in appearance from the Moors of Barbary, whoſe dreſs in travelling he intended to aſſume.

His inſtructions from the aſſociation were, to aſcertain the courſe, and, if poſſible, the riſe and termination of the Niger; and after viſiting the cities of TOMBUCTOO and HOUSSA (ſee theſe articles in this *Supplement*), to return by the way of the deſart, or by any other route which the circumſtances of his ſituation at the time might recommend to his choice.

Having left England on the 16th of October 1790, he arrived at the entrance of the Gambia on the 10th of November, and was kindly received by the king of Barra, who remembered the viſit which the Major had formerly paid him from the iſland of Goree; and who now, in return for a ſmall preſent of the value of 20s. cheerfully tendered protection and aſſiſtance as far as his dominion or influence extended.

Proceedings of the African Aſſociation.

An offer from the maſter of an Engliſh veſſel employed in the trade of the river, enabled the Major, and the interpreter he had engaged on the coaſt, to proceed to Junkiconda; where he purchaſed from the natives a horſe and five aſſes, and prepared to paſs with the merchandiſe which conſtituted his travelling fund, to Medina, the capital of the ſmall kingdom of Woolli.

Fortunately for him, a few words, accidentally dropped by a negro woman in the Mandingo language, of which he had haſtily acquired a ſuperficial knowledge, excited ſuſpicions of danger; and gave him intimation of a conſpiracy which the negro miſtreſſes of the traders, who feared that the Major's expedition portended the ruin of their commerce, had formed againſt his life. Afraid, therefore, of travelling by the cuſtomary route, he availed himſelf of the opportunity which the dry ſeaſon and the tide of ebb afforded of ſwimming his horſe and his aſſes acroſs the ſtream; and having by thoſe means avoided the parties who were ſent for his deſtruction, he proceeded with much difficulty on the ſouthern ſide of the river, to that diſtrict of Cantor which is oppoſite to the kingdom of Woolli. There he repaſſed the Gambia, and ſent a meſſenger to inform the king of his arrival, and to requeſt a guard for his protection.

An eſcort, commanded by the king's ſon, was immediately diſpatched; and the Major, whoſe intended preſent had been announced, was kindly received, and hoſpitably entertained at Medina.

The town is ſituated at the diſtance of about 900 miles by water from the entrance of the Gambia; and the country adjacent abounds in corn and cattle, and, generally ſpeaking, in all things that are requiſite for the ſupport, or eſſential to the comfort of life. Two different ſects of religion diſtinguiſh rather than divide the people; the one is compoſed of the profeſſors of the Mahomedan faith, who are called Buſhreens; the other, and, it is ſaid, the more numerous, conſiſts of thoſe who, denying the miſſion of the prophet, avow themſelves deiſts, and from their cuſtom of drinking with freedom the liquors of which he prohibited the uſe, are denominated Sonikees or drinking men.

In a letter from Major Houghton to his wife, which a ſeaman preſerved from the wreck of a veſſel in which the diſpatches to the ſociety were loſt, the Major indulged the reflections that naturally aroſe from his paſt and preſent ſituations. A bilious fever had attacked him ſoon after his arrival in the Gambia; but his health was now unimpaired—a conſpiracy had aſſailed his life; but the danger was paſſed—the journey from Junkiconda had expoſed him to innumerable hardſhips; but he was now in poſſeſſion of every gratification which the kindneſs of the king or the hoſpitality of the people could enable him to enjoy. Delighted with the healthineſs of the country, the abundance of the game, the ſecurity with which he made his excurſions on horſeback, and above all, with the advantages that would attend the erection of a fort on the ſalubrious and beautiful hill of Fatetenda, where the Engliſh once had a factory, he expreſſes his earneſt hope that his wife will hereafter accompany him to a place in which an income of ten pounds a year will ſupport them in affluence; and that ſhe will participate with him in the pleaſure of rapidly acquiring that vaſt wealth which he imagines its commerce will afford.

While, in this manner, he indulged the dream of future proſperity, and with ſtill more ample ſatisfaction contemplated the eclat of the diſcoveries for which he was preparing, but in the purſuit of which he was retarded by the abſence of the native merchant, for whoſe company he had engaged, he found himſelf ſuddenly involved in unexpected and irreſiſtible misfortune. A fire, the progreſs of which was accelerated by the bambou roofs of the buildings, conſumed with ſuch rapidity the houſe in which he lived, and with it the greateſt part of Medina, that ſeveral of the articles of merchandize, to which he truſted for the expences of his journey, were deſtroyed; and to add to his affliction, his faithleſs interpreter, who had made an ineffectual attempt on his goods, diſappeared with his horſe and three of his aſſes; a trade gun which he had purchaſed on the river ſoon afterwards burſt in his hands, and wounded him in the face and arm: and though the hoſpitable kindneſs of the people of the neighbouring town of Barraconda, who cheerfully opened their houſes to more than a thouſand families, whoſe tene-

ments

Houghton. ments the flames had consumed, was anxiously exerted for his relief; yet the loss of his goods, and the consequent diminution of his travelling fund, were evils which no kindness could remove.

It was in this situation that, wearied with the fruitless hope of the return of the native trader, with whom he had contracted for his journey, he resolved to avail himself of the company of another slave merchant, who was lately arrived from the south, and was now on his way to his farm on the frontier of the kingdom of Bambouk. Accordingly, on the evening of the 8th of May, he proceeded by moon light and on foot, with his two asses, which the servants of the slave merchant offered to drive with their own, and which carried the wreck of his fortune; and journeying by a north-east course, arrived on the fifth day at the uninhabited frontier which separates the kingdoms of Woolli and Bondou.

He had now passed the former limit of European discovery; and while he remarked with pleasure the numerous and extensive population of this unvisited country, he observed, that the long black hair and copper complexion of the inhabitants announced their Arab original. They are a branch of that numerous tribe which, under the appellation of Foolies, have overspread a considerable part of Senegambia; and their religious distinctions are similar to those which prevail in the kingdom of Woolli.

A journey of 150 miles, which was often interrupted by the engagements of his companion, who traded in every town, conducted him to the banks of the Falemé, the south-western boundary of the kingdom of Bambouk. Its stream was exhausted by the advanced state of the dry season, and its bed exhibited an appearance of slate intermixed with gravel.

Bambouk is inhabited by a nation, whose woolly hair and sable complexions bespeak them of the negro race, but whose character seems to be varied in proportion as the country rises from the plains of its western division to the highlands of the east. Distinguished into sects, like the people of Woolli and Bondou, by the different tenets of Mahomedans and Deists, they are equally at peace with each other, and mutually tolerate the respective opinions they condemn.

Agriculture and pasturage, as in the negro states on the coast of the Atlantic, are their chief occupations; but the progress which they have made in the manufacturing arts, is such as enables them to smelt their iron ore, and to furnish the several instruments of husbandry and war. Cloth of cotton, on the other hand, which in this part of Africa seems to be the universal wear, they appear to weave by a difficult and laborious process; and to these two circumstances it is probably owing, that with them the measure of value is not, as on the coast, a bar of iron, but a piece of cloth.

The common vegetable food of the inhabitants appears to consist of rice; their animal, of beef or mutton. A liquor, prepared from fermented honey, supplies the want of wine, and furnishes the means of those festive entertainments that constitute the luxury of the court of Bambouk.

On the Major's arrival at the banks of the river Falemé, he found that the war which had lately subsisted between the kings of Bondou and Bambouk was terminated by the cession to the former of the conquests he had made in the low land part of the dominions of the latter; and that the king of Bondou had taken up his residence in the territory which he had thus obtained. Houghton.

The Major hastened to pay his respects to the victorious prince, and to offer a similar present to that which the kings of Barra and Woolli had cheerfully accepted; but to his great disappointment an ungracious reception, a sullen permission to leave the present, and a stern command to repair to the frontier town from which he came, were followed by an intimation that he should hear again from the king. Accordingly, on the next day, the king's son, accompanied by an armed attendance, entered the house in which the Major had taken up his temporary dwelling, and demanded a sight of all the articles he had brought. From these the prince selected whatever commodities were best calculated to gratify his avarice, or please his eye; and to the Major's great disappointment, took from him the blue coat in which he hoped to make his appearance on the day of his introduction to the Sultan of Tombuctoo. Happily, however, a variety of articles were successfully concealed, and others of inferior value were not considered as sufficiently attractive.

The Major now waited with impatience for the performance of the promise which the slave merchant, with whom he had travelled from the Gambia, had made of proceeding with him to Tombuctoo; but as the merchant was obliged to spend a few days at his rice farm on the banks of the Falemé, the Major accepted an invitation to the hospitality of his roof. There he observed, with extreme regret, that the apprehension of a scarcity of grain had alarmed his friend; and that, dreading the consequences of leaving his family in so perilous a season to the chances of the market, he had determined on collecting, before his departure, a sufficient supply for their support. This argument for delay was too forcible to be opposed; and therefore the Major resolved to employ the interval in visiting the king of Bambouk, who resided in the town of Ferbanna, on the eastern side of the Serra Coles, or river of Gold. Unfortunately, however, by a mistake of his guide, he lost his way in one of the vast woods of the country; and as the rainy season, which commenced with the new moon on the 4th of July, and was introduced with a westerly wind, was now set in, the ground on which he passed the night was deluged with rain, while all the sky exhibited that continual blaze of lightning, which in those latitudes often accompanies the tornado. Distressed by the fever, which began to assail him, the Major continued his route at the break of day, and waded with difficulty through the river Serra Coles, which was swelled by the floods, and on the banks of which the alligators were basking in the temporary sun-shine.

Scarcely had he reached Ferbanna when his fever rose to a height that rendered him delirious; but the strength of his constitution, and the kindness of the negro family to which his guide had conducted him, surmounted the dangerous disease; and in the friendly reception which was given him by the king of Bambouk, he soon forgot the hardships of his journey. The king informed him, that the losses he had lately sustained in the contest with the armies of Bondou, arose from his having exhausted his ammunition; for, as the French traders

Houghton. traders, who formerly supplied his troops, had abandoned the fort of St Joseph, and, either from the dryness of the last season, or from other causes, had deserted the navigation of the upper part of the Senegal, he had no means of replenishing his stores; whereas his enemy, the king of Bondou, continued to receive from the British, through the channel of his agents on the Gambia, a constant and adequate supply.

Major Houghton availed himself of the opportunity which this conversation afforded, to suggest to the king the advantage of encouraging the British to open a trade by the way of his dominions to the populous cities on the banks of the Niger.

Such was the state of the negociation, when all business was suspended by the arrival of the annual presents of Mead, which the people of Bambouk, at that season of the year, are accustomed to send to their king; and which are always followed by an intemperate festival of several successive days.

In the interim, the Major received, and gladly accepted, the proposal of an old and respectable merchant of Bambouk; who offered to conduct him on horseback to Tombuctoo, and to attend him back to the Gambia. A premium of L. 125, to be paid on the Major's return to the British factory at Junkiconda, was fixed by agreement as the merchant's future reward. It was further determined, that the Major should be furnished with a horse in exchange for his two asses; and should convert into gold dust, as the most portable fund, the scanty remains of the goods he had brought from Great Britain.

This plan was much approved by the king, to whom the merchant was personally known; and who gave to the Major at parting, as a mark of his esteem, and a pledge of his future friendship, a present of a purse of gold. With an account of these preparations the Major closed his last dispatch, of the 24th July 1791; and the African association entertained for some time sanguine hopes of his reaching Tombuctoo. Alas! these hopes were blasted. Mr Park, who succeeded him in the arduous task of exploring that savage country, learned, that having reached Jarra (See that article in this *Supplement*), he there met with some Moors who were travelling to Tisheet (a place by the salt pits in the Great Desart, ten days journey to the northward) to purchase salt; and that the Major, at the expence of some tobacco and a musket, engaged them to convey him thither. It is impossible (says Mr Park) to form any other opinion on this determination, than that the Moors intentionally deceived him with a view to rob, and leave him in the Desart. At the end of two days he suspected their treachery, and insisted on returning to Jarra. Finding him persist in this determination, the Moors robbed him of every thing which he possessed, and went off with their camels. Being thus deserted, he returned to a watering place, in possession of the Moors, called Farra; and being by these unfeeling wretches refused food, which he had not tasted for some days, he sunk at last under his misfortunes. Whether he actually died of hunger, or was murdered outright by the savage Mahometans, Mr Park could not learn; but he was shewn at a distance the spot in the woods to which his body was dragged, and where it was left a prey to corruption.

Thus perished, in the prime of life, Major Houghton, a man whose travels enlarged the limits of European discovery, and whose accounts of the places which he visited were strongly confirmed by the intelligence which the British consul at Tunis collected from the Barbary merchants.

Houssa. HOUSSA, the capital of an African empire, on the banks of the Niger, is a city which has excited much curiosity among men of science, since it was first mentioned to a committee of the African Association about the year 1790. The person from whom they received their information was an Arab, of the name of Shabeni; who said that the population of Houssa, where he had resided two years, was equalled only (so far as his knowledge extended) by that of London and Cairo: and, in his rude unlettered way, he described the government as monarchical, yet not unlimited; its justice as severe, but directed by written laws; and the rights of landed property as guarded by the institutions of certain hereditary officers, whose functions appear to be similar to those of the Canongoes of Hindostan (See Canongoes, in this *Suppl.*); and whose important and complicated duties imply an unusual degree of civilization and refinement. For the probity of the merchants of Houssa, the Arab expressed the highest respect; but remarked, with indignation, that the women were admitted to society, and that the honour of the husband was often insecure. Of their written alphabet he knew no more, than that it is perfectly different from the Arabic and the Hebrew characters; but he represented the art of writing as common in Houssa. And when he described the manner in which their pottery is made, he gave, unknowingly to himself, a representation of the ancient Grecian wheel. In passing to Houssa from Tombuctoo, in which last city he had resided seven years, he found the banks of the Niger more numerously peopled than those of the Nile, from Alexandria to Cairo; and his mind was obviously impressed with higher ideas of the wealth and grandeur of the empire of Houssa, than of those of any kingdom which he had seen, England alone excepted.

The existence of the city of Houssa, and of the empire thus described by Shabeni, was strongly confirmed by letters which the committee received from his Majesty's consuls at Tunis and Morocco; and it has been put beyond all possibility of doubt by Mr Park, who received from various persons such concurring accounts of it, as could not be the offspring of deliberate falsehood. From a well informed shereeff, who had visited Houssa, and lived some years at Tombuctoo, he learned, that the former of these cities was the largest that the shereeff had ever seen; and by comparing this man's account of its population with that of various other cities, of which Mr Park had seen one or two, we can hardly estimate the inhabitants of Houssa at a less number than 100,000. Many merchants, with whom our traveller conversed, represented Houssa as larger, and more populous than Tombuctoo, and the trade, police, and government as nearly the same in both. In that case, the king of Houssa and chief officers of state must be Moors, and zealots for the Mahometan religion; but they cannot be so intolerant as the sovereign of Tombuctoo and his ministers; for in Houssa, Mr Park was told that the negroes are in greater proportion to the Moors than in Tombuctoo, and that they have likewise some share in the government. According to accounts

counts derived from Barbary merchants, the people of Houssa have the art of tempering their iron with more than European skill; and their files in particular are much superior to those of Great Britain and France. The consuls at Tunis and Morocco assured the committee of the African Association, that at both these courts the eunuchs of the seraglio are brought from Houssa.

To those who may still entertain doubts of so much refinement being to be found in the interior parts of a country, considered as peculiarly savage, we shall only observe, in the words of the committee of association, that it is by no means "impossible that the Carthaginians, who do not appear to have perished with their cities, may have retired to the southern parts of Africa; and though lost to the Desart, may have carried with them to the new regions which they occupy, some portion of those arts and sciences, and of that commercial knowledge, for which the inhabitants of Carthage were once so eminently famed. In Major Rennel's last map of North Africa, Houssa is placed in 16° and about 20′ N. L. and 4° 30′ E. Long.

HOUSATONICK, a river of Connecticut, in the Indian language signifying *over the mountain*, rises by two sources; the one in Lanesborough, the other in Windsor, both in Berkshire county, Massachusetts. These branches form a junction near Salisbury, and the river after passing through a number of towns, empties itself into Long-Island Sound, between Stratford and Milford in Connecticut. It is navigable about 12 miles, to Derby. A bar of shells, however, at its mouth, obstructs the navigation of large vessels. In this river, between Salisbury and Canaan, is a cataract, where the water of the whole river, which is 150 yards wide, falls perpendicularly 60 feet.—*Morse.*

HOUZOUANAS are a wandering people, who inhabit that part of Africa, which, in a direction from east to west, extends from Caffraria to the country of the Greater Nimiquas (see NIMIQUAS, in this *Suppl.*) According to the map prefixed to Vaillant's new travels, the district occupied by the Houzouanas lies between 16° and 29° east longitude. Of its breadth from south to north we are ignorant; but it begins at the 23d parallel, and stretches northward probably a great way.

M. Vaillant is inclined to believe, that the Houzouanas are the original stem of the various nations, inhabiting at present the southern part of Africa, and that from them all the tribes of the eastern and western Hottentots are descended. The people themselves know nothing of their origin; but to the questions that are put to them on the subject, they always reply, that they inhabit the country which was inhabited by their ancestors. At the Cape, M. Vaillant received the following account of them, which, though he does not warrant its authenticity, has much the appearance of being authentic.

When the Europeans first established themselves at the Cape, the Houzouanas inhabited the country of Camdebo, the snowy mountains, and the district that separates these mountains from Caffraria. Become neighbours to the colony, in consequence of its extending itself towards them, they at first lived on peaceable terms with the planters; and, as they displayed more intelligence and greater activity than the Hottentots, they were even employed in preference to assist in cultivating the land and in forming the settlement. This good understanding and harmony were, however, soon interrupted by that multitude of lawless banditti sent from Holland to people the country.

These worthless profligates wished to enjoy the fruits of the land without the trouble of tilling it. Educated, besides, with all the prejudices of the whites, they imagined that men of a different colour were born only to be their slaves. They accordingly subjected them to bondage, condemned them to the most laborious services, and repaid those services with harsh and severe treatment. The Houzouanas, incensed at such arbitrary and tyrannical conduct, refused any longer to work for them, and retired to the defiles of their mountains. The planters took up arms and pursued them; they massacred them without pity, and seized on their cattle and their country. Those who escaped their atrocities betook themselves to flight, and removed to the land which they now occupy; but, on quitting their former possessions, they swore, in their own name and that of their posterity, to exterminate these European monsters, to be revenged against whom they had so many incitements. And thus, if tradition be true, was a peaceful and industrious nation rendered warlike, vindictive, and ferocious.

This hatred has been perpetuated from generation to generation, though the Houzouanas of the present day are ignorant of the original cause of it. Bred up with an invincible aversion to the planters, they know only that they are animated to plunder and destroy them; but it is only by a vague sentiment of detestation, with the source of which they are unacquainted; and which, though it renders them cruel towards the planters, does not prevent them from being good, kind, and humane, towards each other.

The Houzouanas, being known only by their incursions and plundering, are in the colonies often confounded with the Boshmen, and distinguished by the same appellation. Sometimes, however, from their tawny colour, they are called Chinese Hottentots; and, by means of this double denomination, ill-informed travellers may easily be led into an error, of which the consequence must be, that their narratives will be replete with absurdity and falsehoods.

Their real name, and the only one which they give themselves, is that of Houzouana; and they have nothing in common with the Boshmen, who are not a distinct people, but a mere collection of fugitives and free-booters. The Houzouanas form no alliances but among themselves. Being almost always at war with the surrounding nations, they never mix with them; and, if they consent at any time to admit a stranger into their hordes, it is only after a long acquaintance, a sort of apprenticeship, during which he has given proofs of his fidelity, and established his courage. Such indeed are their courage and predatory habits, that they are the dread of all the surrounding tribes; and the Hottentots who accompanied M. Vaillant trembled at the very thought of entering the Houzouana territories. Nay, after they had lived many days among them, and had experienced their fidelity, they continued under the daily apprehension of being massacred by them. Yet one of their own countrymen, who had lived long among the Houzouanas, gave such a character of that people as should have banished those idle fears.

"The Houzouanas (said he) are by no means what you suppose them to be, murderers by profession. If they sometimes shed blood, it is not from a thirst of carnage, but to make just reprisals that they take up arms. Attacked and persecuted by surrounding nations, they have found themselves reduced to the necessity of flying to inaccessible places among the barren mountains, where no other people could exist.

"If they find antelopes and damans to kill; if the nymphs of ants are abundant; or if their good fortune brings them plenty of locusts—they remain within the precincts of their rocks; but if the provisions necessary to subsistence fail, the nations in their neighbourhood must suffer. From the summits of their mountains, they survey at a distance the countries around; and, if they observe cattle, they make an incursion to carry them off, or slaughter them upon the spot, according to circumstances; but though they rob, they never kill, except to defend their lives, or by way of retaliation to revenge an ancient injury.

"It happens sometimes, however, that after very fatiguing expeditions they return without booty; either because the objects of their attack have disappeared, or because they have been repulsed and beaten. In such cases, the women, exasperated by hunger and the lamentation of their children crying for food, become almost furious with passion. Reproaches, insult, and threats, are employed; they wish to separate from such dastardly men, to quit husbands destitute of courage, and to seek others who will be more anxious to procure provision for them and their children. In short, having exhausted whatever rage and despair could suggest, they pull off their small apron of modesty, and beat their husbands about the head with it till their arms are weary of the exercise.

"Of all the affronts which they can offer, this is the most insulting. Unable to withstand it, the men in their turn become furious. They put on their war-cap, a sort of helmet made with the skin that covers the neck of the hyæna, the long hair of which forms a crest that floats over the head, and, setting out like madmen, never return till they have succeeded in carrying off some cattle.

"When they come back, their wives go to meet them, and extol their courage amidst the fondest caresses. In a word, nothing is then thought of but mirth and jollity; and, till similar scenes are recalled by similar wants, past evils are forgotten."

Such was the character given of this formidable people to M. Vaillant at his first interview with them; and during the long excursions which he made in their company they did not belie it in a single instance. In many respects they appeared to resemble the Arabs, who, being also wanderers, and like them brave and addicted to rapine, adhere with unalterable fidelity to their engagements, and defend, even to the last drop of their blood, the traveller who civilly purchases their services, and puts himself under their protection. In our author's opinion, if it be at all practicable to traverse from south to north the whole of Africa, it could only be under the conduct of the Houzouanas; and he really thinks that fifty men of their temperate, brave, and indefatigable nation, would be sufficient to protect an enterprizing European through that long and hazardous journey.

Yet these people, so superior both in body and mind to the other natives of South Africa, are but of low stature; and a person five feet four inches in height is accounted among them very tall; but in their little bodies, perfectly well proportioned, are united, with surprising strength and agility, a certain air of assurance, boldness, and haughtiness, which awes the beholder, and with which our author was greatly pleased. Of all the savage races, he saw none that appeared to be endowed with so active a mind, and so hardy a constitution.

Their head, though it exhibits the principle characteristics of that of the Hottentot, is, however, rounder towards the chin. They are also not so black in complexion; but have the lead colour of the Malays, distinguished at the Cape by the name of *louguinée*. Their hair, more woolly, is so short that he imagined at first their heads to have been shaved. The nose too is still flatter than that of the Hottentots; or, rather, they seem altogether destitute of a nose; what they have consisting only of two broad nostrils which project at most but five or six lines. From this conformation of the nose, a Houzouana, when seen in profile, is the reverse of handsome, and considerably resembles an ape. When beheld in front, he presents, on the first view, an extraordinary appearance, as half the face seems to be forehead. The features, however, are so expressive, and the eyes so large and lively, that, notwithstanding this singularity of look, the countenance is tolerably agreeable.

As the heat of the climate in which he lives renders clothing unnecessary, he continues during the whole year almost entirely naked, having no other covering than a very small jackal skin fastened round his loins by two thongs, the extremities of which hang down to his knees. Hardened by this constant habit of nakedness, he becomes so insensible to the variations of the atmosphere, that when he removes from the burning sands of the level country to the snow and hoar-frost of his mountains, he seems indifferent to, and not even to feel the cold.

His hut in no wise resembles that of the Hottentot. It appears as if cut vertically through the middle; so that the hut of a Hottentot would make two of those of the Houzouanas. During their emigrations, they leave them standing, in order that, if any other horde of the same nation pass that way, they may make use of them. When on a journey, they have nothing to repose on but a mat suspended from two sticks, and placed in an inclined position. They often even sleep on the bare ground. A projecting rock is then sufficient to shelter them; for every thing is suited to a people whose constitutions are proof against the severest fatigue. If however they stop anywhere to sojourn for a while, and find materials proper for constructing huts, they then form a kraal; but they abandon it on their departure, as is the case with all the huts which they erect.

This custom of labouring for others of their tribe announces a social character and a benevolent disposition. They are indeed not only affectionate husbands and good fathers, but excellent companions. When they inhabit a kraal, there is no such thing among them as private property; whatever they possess is in common.

mon. If two hordes of the same nation meet, the reception is on both sides friendly; they afford each other mutual protection, and confer reciprocal obligations. In short, they treat one another as brethren, though perhaps they are perfect strangers, and have never seen each other before.

Active and nimble by nature, the Houzouanas consider it as amusement to climb mountains, and the most elevated peaks; and they conducted M. Vaillant, his servants and cattle, over precipices, and through defiles, which he and his Hottentots would have deemed absolutely impassable. The only arms of this people are bows and arrows, in the use of which they are very expert. The arrows, which are uncommonly short, are carried on the shoulder in a quiver, about eighteen inches in length, and four in diameter, made of the bark of the aloe, and covered with the skin of a large species of lizard, which these wanderers find in all their rivers, particularly on the banks of Orange and Fish River.

Nocturnal fires are a peculiar language understood and employed by almost all savage nations. None, however, have carried this art so far as the Houzouanas, because none have so much need of understanding and bringing it to perfection. If it be necessary to announce a defeat or a victory, an arrival or departure, a successful plundering expedition, or the want of assistance, in a word, any intelligence whatever, they are able, either by the number of their fires or the manner in which they arrange them, to make it known in an instant. They are even so sagacious as to vary their fires from time to time, lest their enemies should become acquainted with their signals, and treacherously employ them in their turn to surprise them.

Our author says that he is unacquainted with the principles of these signals, invented with so much ingenuity. He did not request information; because he very rationally inferred that his request would not have been granted; but he observed, that three fires kindled at the distance of twenty paces from each other, so as to form an equilateral triangle, were the signal for rallying.

Among the physical qualities, which, in M. Vaillant's opinion, prove that the Houzouanas are a distinct nation, he mentions the enormous natural rump of the women, as a deformity which distinguishes them from every other people, savage or polished, which he had ever known. "I have several times (says he) had occasion to remark, that, among the female Hottentots in general, as they advance in age, the inferior part of the back swells out, and acquires a size which greatly exceeds the proportion it bore in infancy with the other parts of the body. The Houzouana women, having in their figure some resemblance to the Hottentots, and appearing, therefore, to be of the same race, one might be induced to believe that their projection behind is only the Hottentot rump more swelled and extended. I observed, however, that among the former this singularity was an excrescence of slow growth, and in some measure an infirmity of old age; whereas among the latter it is a natural deformity, an original characteristic of their race. The Houzouana mothers wear on their reins, like our miners, a skin which covers this protuberance of the posteriors; but which, being thin and pliable, yields to the quivering of the flesh, and becomes agitated in the same manner. When on a journey, or when they have children too young to follow them, they place them upon their rump. I saw one of these women run in this manner with a child, about three years of age, that stood erect on its feet at her back, like a foot boy behind a carriage."

If one half of what our traveller says of the activity and enterprising spirit of this singular people be true, might not the African Association, now that the Cape is a British province, send a second Houghton, or second Park, to make discoveries in that unexplored country, under the protection of the Houzouanas? We do not indeed think that it would be possible to traverse the whole extent of Africa from south to north, but Vaillant penetrated farther in that direction than any one had done before him; and it appears, that with his intrepid Houzouanas he might have penetrated much farther.

HOWLAND'S *Ferry*, is the narrow part of the waters that separate Rhode-Island from the main land. It is about a quarter of a mile wide. The bridge built across this strait cost 30,000 dollars, and was carried away by a storm in January, 1796. It is rebuilt.—*Morse.*

HUBBARDSTON, a township in Worcester county, Massachusetts, and formed the N. E. quarter of Rutland, until incorporated in 1767. It borders on the western part of Wachuset Hill, and contains 933 inhabitants. It is 20 miles N. W. of Worcester, and 60 W. of Boston.—*ib.*

HUDSON'S BAY took its name from Henry Hudson, who discovered it in 1610. It lies between 55 and 65 degrees of north latitude. The eastern boundary of the bay is Terra de Labrador; the northern part has a straight coast, facing the bay, guarded with a line of isles innumerable. A vast bay, called the Archiwinnipy Sea, lies within it, and opens into Hudson's Bay, by means of Gulf Hazard, through which the Beluga whales pass in great numbers. The entrance of the bay, from the Atlantic Ocean, after leaving, to the north, Cape Farewell and Davis's Straits, is between Resolution Isles on the north, and Button's Isles, on the Labrador coast, to the south, forming the eastern extremity of Hudson's Straits. The coasts are very high, rocky and rugged at top; in some places precipitous, but sometimes exhibit extensive beaches. The islands of Salisbury, Nottingham, and Digges are very lofty and naked. The depth of water in the middle of the bay is 140 fathoms. From Cape Churchill to the south end of the bay, are regular soundings; near the shore, shallow, with muddy or sandy bottom. To the northward of Churchill, the soundings are irregular, the bottom rocky, and in some parts the rocks appear above the surface at low water. Hudson's Bay is reckoned about 300 leagues wide, from north to south. Its breadth is unequal, being about 130 leagues where broadest: but it grows narrower at both extremities, being not much above 35 leagues in some places. The commerce in the countries adjacent to this inland sea is in the hands of an exclusive British Company of its name, who employ only 4 ships, and 130 seamen. The forts, Prince of Wales, Churchill river, Nelson, New Severn, and Albany, are garrisoned by 186 men. The French, in 1782, took and destroyed these settlements, &c. said to amount to the value of £500,000 sterling. The

Hudson's. Company's exports are to the amount of £16,000, mostly the drugs of the market, which produce returns, chiefly in beaver skins and rich furs, to the value of £29,000; yielding government a clear revenue of £3,734. This includes the fishery in Hudson's Bay. The skins and furs procured by this trade, when manufactured, afford articles for trading with many nations of Europe, to great advantage.—*ib.*

HUDSON'S STRAIT, or *Frobisher's Mistaken Strait*, which leads into Hudson's Bay, in a westerly course is 76 miles wide, between Cape Chidley and the S. point of Resolution Island.—*ib.*

HUDSON'S HOUSE, one of the Hudson's Bay Company's factories in N. America, lies on the S. W. side of Suskashawan river, 100 miles east of Manchester House, and 167 S. E. by E. of Buckingham House. N. lat. 53° 0' 32", W. long. 106° 27' 20".—*ib.*

HUDSON'S RIVER passes its whole course in the State of New-York, and is one of the largest and finest rivers in the United States. It rises in a mountainous country, between the lakes Ontario and Champlain. In its course southeasterly it approaches within 6 or 8 miles of lake George; then, after a short course E. turns southerly, and receives the Sacondaga from the S W. which heads in the neighbourhood of Mohawk river. The course of the river thence to New-York, where it empties into York Bay, is very uniformly S. 12° or 15° W. Its whole length is about 250 miles. From Albany to lake George is 65 miles. This distance, the river is navigable only for batteaux, and has two portages, occasioned by falls, of half a mile each. The banks of Hudson's river, especially on the western side, as far as the highlands extend, are chiefly rocky cliffs. The passage through the highlands, which is 16 or 18 miles, affords a wild romantic scene. In this narrow pass, on each side of which the mountains tower to a great height, the wind, if there be any, is collected and compressed, and blows continually as through a bellows; vessels, in passing through it are often obliged to lower their sails. The bed of this river, which is deep and smooth to an astonishing distance, through a hilly, rocky country, and even through ridges of some of the highest mountains in the United States, must undoubtedly have been produced by some mighty convulsion in nature. The tide flows a few miles above Albany, which is 160 miles from New-York. It is navigable for sloops of 80 tons to Albany, and for ships to Hudson. Ship navigation to Albany is interrupted by a number of islands, and shoals 6 or 8 miles below the city, called the *Overslaugh*. It has been in contemplation to confine the river to one channel, by which means it will be deepened, and the difficulty of approaching Albany with vessels of a larger size, be removed. About 60 miles above New-York the water becomes fresh. The river is stored with a variety of fish, which renders a summer passage to Albany, delightful and amusing to those who are fond of angling. The advantages of this river for carrying on the fur trade with Canada, by means of the lakes, are very great. Its conveniencies for internal commerce are singularly happy. The produce of the remotest farms is easily and speedily conveyed to a certain and profitable market, and at the lowest expense. In this respect, New-York has greatly the advantage of Philadelphia. A great proportion of the produce of Pennsylvania, is carried to market in waggons, over a great extent of country, some of which is rough; hence it is that Philadelphia is crowded with waggons, carts, horses and their drivers, to do the same business that is done in New-York, where all the produce of the country is brought to market by water, with much less shew and parade. But Philadelphia has other advantages, to compensate for this natural defect. The increasing population of the fertile lands upon the northern branches of the Hudson, must annually increase the amazing wealth that is conveyed by its waters to New-York. The northern and western canals, when completed, will be of incalculable advantage to the trade of this State.—*ib.*

HUDSON'S RIVER, a broad but short river emptying into Chesapeak Bay, in Dorchester county, Maryland. Hill's Point, N. E. of it, shapes the broad mouth of the river.—*ib.*

HUDSON CITY, a port of entry and post town situated in Columbia county, New-York, on the east side of Hudson's river, 30 miles S. by E. of Albany, and 132 north of New-York city. The limits of the corporation include a square mile, and its privileges as a port of entry extend no farther. In the autumn of 1783, Messrs. Seth and Thomas Jenkins, from Providence, in the State of Rhode-Island, fixed on the unsettled spot, whereon this city stands, for a town, to which the city is navigable for vessels of any size. The city is laid out into large squares, bordering on the river, and divided into 30 lots. Other adventurers were admitted to proportions, and the town was laid out in squares, formed by spacious streets, crossing each other at right angles. Each square contains 30 lots, two deep, divided by a 20 feet alley. Each lot is 50 feet in front and 120 feet in depth. In the spring of 1784, several houses and stores were erected. The increase of the town from this period to the spring of 1786, two years only, was astonishingly rapid, and reflects great honour upon the enterprising and persevering spirit of the original founders. In the space of time just mentioned no less than 150 dwelling houses, besides shops, barns, and other buildings, four ware-houses, several wharves, spermaceti works, a covered rope-walk, and one of the best distilleries in America, were erected, and 1,500 souls collected on a spot, which three years before, was improved as a farm, and but two years before began to be built. Its increase since has been very rapid; a printing-office has been established, and several public buildings have been erected, besides dwelling houses, stores, &c. The inhabitants are plentifully and conveniently supplied with water, brought to their cellars in wooden pipes, from a spring two miles from the town. It has a large bay to the southward, and stands on an eminence from which are extensive and delightful views to the N. W. N. and round that way to the S. E. consisting of hills and vallies, variegated with woods and orchards, corn-fields and meadows, with the river, which is in most places a mile over, and may be seen a considerable distance to the northward, forming a number of bays and creeks. From the S. E. to the S. W. the city is screened with hills, at different distances, and west afar off over the river and a large valley, the prospect is bounded by a chain of stupendous mountains, called the Katts Kill, running to the W. N. W. which add

Hugheſburg, || Hummel's town.

magnificence and ſublimity to the whole ſcene. Upwards of 1200 ſleighs entered the city daily, for ſeveral days together, in February, 1786, loaded with grain of various kinds, boards, ſhingles, ſtaves, hoops, iron ware, ſtone for building, fire-wood, and ſundry articles of proviſion for the market, from which ſome idea may be formed of the advantage of its ſituation, with reſpect to the country adjacent, which is every way extenſive and fertile, particularly weſtward. The original proprietors of Hudſon, offered to purchaſe a tract of land adjoining the ſouth part of the city of Albany, and were conſtrained, by a refuſal of the propoſition, to become competitors for the commerce of the northern country, when otherwiſe they would have added great wealth and conſequence to Albany. There is a bank here, called Bank of Columbia, whoſe capital may not exceed 160,000 dollars. It is compoſed of 400 ſhares, at 400 dollars each. Hudſon city is governed by a mayor, recorder, 4 aldermen, 4 aſſiſtants, and a number of other officers. The number of inhabitants in *Hudſon Townſhip*, by the cenſus of 1790, amounted to 2,584, including 193 ſlaves; and it appears by the State cenſus of 1796 that 338 of the inhabitants are electors. Hudſon city is 4 miles S. W. of Claverack; 47 north of Poughkeepſie; and 43 ſouth of Lanſinburg.—*ib.*

HUGHESBURG, a town in Northumberland county, Pennſylvania, called alſo *Cataweſſy*, being ſituated at the mouth of Catawеſſy creek, 25 miles N. E. of Sunbury. It contains about 60 handſome houſes, and a meeting houſe for Friends. It is 144 miles N. W. of Philadelphia. N. lat. 40° 54'.—*ib.*

HULL, an inconſiderable town in Suffolk county, on the ſouth ſide of Boſton harbour, Maſſachuſetts, containing 120 inhabitants. On the fort on the eaſt hill there is a well ſunk 90 feet, which commonly has 80 odd feet of water.—*ib.*

HUMAS, an Indian village on the eaſt ſide of Miſſiſſippi river in Louiſiana, 60 miles above New Orleans. The Humas were formerly a conſiderable nation, but about 1770 were reduced to about 25 warriors. The Alabamas, whoſe villages are near thoſe of the Humas, had, at the above period, about 30 warriors, and followed the French here when they abandoned the poſt on Alabama river in 1762. The Chetimachas have about 27 warriors.—*ib.*

HUMMEL'S TOWN, a thriving town in Dauphine county, Pennſylvania, containing a German Lutheran church and about 90 houſes; ſituated on the ſouth ſide of Swetara creek, 6 miles north of Middletown, 10 E. by N. of Harriſburg, and 100 weſt-north-weſt of Philadelphia.—*ib.*

Hungary.

HUNGARY-WATER, is ſpirit of wine diſtilled upon roſemary, and which therefore contains its oily and ſtrong ſcented eſſence (ſee PHARMACY, n° 365, *Encycl.)*. To be really good, ſays Profeſſor Beckmann, the ſpirit of wine ought to be very ſtrong, and the roſemary freſh; and if that be the caſe, the leaves are as proper as the flowers, which, according to the preſcription of ſome, ſhould only be taken. It is likewiſe neceſſary that the ſpirit of wine be diſtilled ſeveral times upon the roſemary; but that proceſs is too troubleſome and expenſive to admit of this water being diſpoſed of at the low price it is uſually ſold for; and it is certain, that the greater part of it is nothing elſe than common brandy, united with the eſſence of roſemary in the ſimpleſt manner. In general, it is only mixed with a few drops of the oil. For a long time paſt, this article has been brought to us principally from France, where it is prepared, particularly at Beaucaire, Montpellier, and other places in Languedoc, in which that plant grows in great abundance.

Hiſt. of Inventions.

The name Hungary water ſeems to ſignify, that this water, ſo celebrated for its medicinal virtues is an Hungarian invention; and we read in many books, that the receipt for preparing it was given to a queen of Hungary by a hermit; or, as others ſay, by an angel, who appeared to her in a garden, all entrance to which was ſhut, in the form of a hermit or a youth. Some call the queen St Iſabella; but thoſe who pretend to be beſt acquainted with the circumſtance affirm, that Elizabeth, wife of Charles Robert king of Hungary, and daughter of Uladiſlaus II. king of Poland, who died in 1380 or 1381, was the inventreſs. By often waſhing with this ſpirit of roſemary, when in the 70th year of her age, ſhe was cured, as we are told, of the gout and an univerſal lameneſs; ſo that ſhe not only lived to paſs 80, but became ſo lively and beautiful, that ſhe was courted by the king of Poland, who was then a widower, and who wiſhed to make her his ſecond wife.

The Profeſſor juſtly conſiders this ſtory as a ridiculous fable (A). "It appears to me (ſays he) moſt probable, that the French name *l'eau de la reine d' Hongrie*, was choſen by thoſe who, in latter times, prepared ſpirit of roſemary for ſale, in order to give greater conſequence and credit to their commodity; as various medicines

(A) It was firſt publiſhed to the world in 1659 in a poſthumous work of John Prevot, who ſays that in the beginning of a very old breviary, he ſaw a remedy for the gout, written by the queen's own hand, in the following words:

"I Elizabeth, queen of Hungary, being very infirm and much troubled with the gout in the 72d year of my age, uſed for a year this receipt, given to me by an ancient hermit, whom I never ſaw before nor ſince; and was not only cured, but recovered my ſtrength, and appeared to all ſo remarkably beautiful, that the king of Poland aſked me in marriage, he being a widower and I a widow. I, however, refuſed him for the love of my Lord Jeſus Chriſt, from one of whoſe angels, I believe, I received the remedy. The receipt is as follows:

"R. Take of aqua vitæ, four times diſtilled, three parts, and of the tops and flowers of roſemary two parts: put theſe together in a cloſe veſſel, let them ſtand in a gentle heat 50 hours, and then diſtil them. Take one dram of this in the morning once every week, either in your food or drink, and let your face and the diſeaſed limb be waſhed with it every morning.

"It renovates the ſtrength, brightens the ſpirits, purifies the marrow and nerves, reſtores and preſerves the ſight, and prolongs life." Thus far from the Breviary. Then follows a confirmation which Prevot gives from his own experience.

Hunger-ford, Hunter.

dicines, ſome years ago, were extolled in the gazettes under the title of Pompadour, though the celebrated lady, from whoſe name they derived their importance, certainly neither ever ſaw them nor uſed them."

HUNGERFORD, a townſhip in Franklin county, Vermont, containing 40 inhabitants, 7 miles ſouth of the Canada line and 14 eaſt of Lake Champlain.—*Morse.*

HUNGER CREEK, a ſtream which carries the various water machinery, in the new and thriving manufacturing town of Hamilton, between Albany and Schenectady, New-York.—*ib.*

HUNTER (John), the celebrated ſurgeon, was the youngeſt child of John Hunter of Kilbride, in the county of Lanark. He was born on the 14th of July 1728, at Long Calderwood, a ſmall eſtate belonging to the family; and loſing his father when he was about ten years of age, he was, perhaps, too much indulged by his mother. One conſequence of this was, that at the grammar-ſchool he made no progreſs in learning; and he may be ſaid to have been almoſt totally illiterate when, in September 1748, he arrived in London. His brother, Dr William Hunter, of whom an account is given in the *Encyclopædia*, was then the moſt celebrated teacher of anatomy, and John had expreſſed a deſire to aſſiſt him in his reſearches. The Doctor, who was very deſirous to ſerve him, and anxious to form ſome opinion of his talents for anatomy, gave him an arm to diſſect for the muſcles, with the neceſſary directions how it was to be done; and he found the performance ſuch as greatly exceeded his expectation.

His firſt eſſay in anatomy having thus gained him ſome credit, Mr Hunter was now employed in a diſſection of a more difficult nature; this was an arm in which all the arteries were injected, and theſe, as well as the muſcles, were to be expoſed and preſerved. The manner in which this was performed, gave Dr Hunter ſo much ſatisfaction, that he did not ſcruple to ſay, that his brother would become a good anatomiſt, and that he ſhould not want for employment. From this period we may conſider Mr Hunter as having ſeriouſly engaged in anatomy; and under the inſtructions of Dr Hunter, and his aſſiſtant Mr Symonds, he had every opportunity of improvement, as all the diſſections at this time carried on in London were confined to that ſchool.

In the ſummer 1749, Mr Cheſelden, at the requeſt of Dr Hunter, permitted him to attend at Chelſea Hoſpital; and he there learned the firſt rudiments of ſurgery.

The following winter he was ſo far advanced in the knowledge of human anatomy, as to inſtruct the pupils in diſſection, to whom Dr Hunter had very little time to pay attention. This office, therefore, fell almoſt entirely upon him, and was his conſtant employment during the winter ſeaſon.

In the ſummer months of 1750, Mr Hunter attended the hoſpital at Chelſea; in 1751, he became a pupil at St Bartholomew's, and in the winter was preſent at operations occaſionally, whenever any thing extraordinary occurred. The following ſummer he went to Scotland; and in 1753 entered, it is difficult to conceive for what reaſon, as a gentleman commoner at St Mary hall, Oxford. In 1754 he became a ſurgeon's pupil at St George's hoſpital, where he continued during the ſummer months; and in 1756 was appointed houſe-ſurgeon.

In the winter 1755, Dr Hunter admitted him to a partnerſhip in his lectures, and a certain portion of the courſe was allotted to him; beſides which, he gave lectures when the Doctor was called away to attend his patients. Making anatomical preparations was at this time a new art, and very little known; every preparation, therefore, that was ſkilfully made, became an object of admiration; many were wanting for the uſe of the lectures; and the Doctor being himſelf an enthuſiaſt for the art, left no means untried to infuſe into his brother a love for his favourite purſuits. How well he ſucceeded, the collection afterwards made by Mr Hunter will ſufficiently evince. Hunter.

Anatomy ſeems to have been a purſuit for which Mr Hunter's mind was peculiarly fitted, and he applied to it with an ardour and perſeverance of which there is hardly any example. His labours were ſo uſeful to his brother's collection, and ſo gratifying to his diſpoſition, that although in many other reſpects they did not agree, this ſimple tie kept them together for many years.

Mr Hunter worked for ten years on human anatomy, during which period he made himſelf maſter of what was already known, as well as made ſome addition to that knowledge. He traced the ramifications of the olfactory nerves upon the membranes of the noſe, and diſcovered the courſe of ſome of the branches of the fifth pair of nerves. In the gravid uterus, he traced the arteries of the uterus to their termination in the placenta. He was alſo the firſt who diſcovered the exiſtence of the lymphatic veſſels in birds.

Many parts of the human body being ſo complex, that their ſtructure could not be underſtood, nor their uſes aſcertained, Mr Hunter was led to examine ſimilar parts in other animals, in which the ſtructure was more ſimple, and more within the reach of inveſtigation; this carried him into a wide field, and laid the foundation of his collection in comparative anatomy.

In this new line of purſuit, this active inquirer began with the more common animals, and preſerved ſuch parts as appeared by their analogy, or in ſome other way, to elucidate the human economy. It was not his intention to make diſſections of particular animals, but to inſtitute an inquiry into the various organizations by which the functions of life are performed, that he might thereby acquire ſome knowledge of general principles.

So eagerly did Mr Hunter attach himſelf to comparative anatomy, that he ſought by every means in his power the opportunities of proſecuting it with advantage. He applied to the keeper of wild beaſts in the Tower for the bodies of thoſe which died there; and he made ſimilar applications to the men who ſhowed wild beaſts. He purchaſed all rare animals which came in his way; and theſe, with ſuch others as were preſented to him by his friends, he entruſted to the ſhowmen to keep till they died, the better to encourage them to aſſiſt him in his labours.

His health was ſo much impaired by exceſſive attention to his purſuits, that in the year 1760 he was adviſed to go abroad, having complaints in his breaſt, which threatened to be conſumptive. In October of that year, Mr Adair, inſpector-general of hoſpitals, appointed him a ſurgeon on the ſtaff; and in the following ſpring he went with the army to Belliſle, leaving Mr Hewſon to aſſiſt his brother during his abſence.

Mr Hunter ferved, while the war continued, as fenior furgeon on the ftaff, both in Bellifle and Portugal, till the year 1763; and in that period acquired his knowledge of gun-fhot wounds. On his return to England he fettled in London; where, not finding the emoluments from his half-pay and private practice fufficient to fupport him, he taught practical anatomy and operative furgery for feveral winters. He returned alfo, with unabated ardour, to comparative anatomy; and as his experiments could not be carried on in a large town, he purchafed for that purpofe, about two miles from London, a piece of ground near Brompton, at a place called Earl's Court, on which he built a houfe. In the courfe of his inquiries, this excellent anatomift afcertained the changes which animal and vegetable fubftances undergo in the ftomach when acted on by the gaftric juice; he difcovered, by means of feeding young animals with madder (which tinges growing bones red), the mode in which a bone retains its fhape during its growth; and explained the procefs of exfoliation, by which a dead piece of bone is feparated from the living.

His fondnefs for animals made him keep feveral of different kinds in his houfe, which by attention he rendered familiar with him, and amufed himfelf by obferving their peculiar habits and inftincts; but this familiarity was attended with confiderable rifk, and fometimes led him into fituations of danger, of which the following is a remarkable inftance:

Two leopards, which were kept chained in an outhoufe, had broken from their confinement, and got into the yard among fome dogs, which they immediately attacked; the howling this produced alarmed the whole neighbourhood; Mr Hunter ran into the yard to fee what was the matter, and found one of them getting up the wall to make his efcape, the other furrounded by the dogs; he immediately laid hold of them both, and carried them back to their den; but as foon as they were fecured, and he had time to reflect upon the rifk of his own fituation, he was fo much agitated, that he was in danger of fainting.

On the fifth of February 1767, he was chofen a fellow of the Royal Society. His defire for improvement in thofe branches of knowledge which might affift in his refearches, led him at this time to propofe to Dr George Fordyce and Mr Cumming, an eminent mechanic, that they fhould adjourn from the meetings of the Royal Society to fome coffee-houfe, and difcufs fuch fubjects as were connected with fcience. This plan was no fooner eftablifhed, than they found their numbers increafed; they were joined by Sir Jofeph Banks, Dr Solander, Dr Mafkelyne, Sir George Shuckburgh, Sir Harry Englefield, Sir Charles Blagden, Dr Noothe, Mr Ramfden, Mr Watt of Birmingham, and many others. At thefe meetings difcoveries and improvements in different branches of philofophy were the objects of their confideration; and the works of the members were read over and criticifed before they were given to the public. It was in this year that, by an exertion in dancing, after the mufcles of the leg were fatigued, he broke his tendo achillis. This accident, and the confinement in confequence of it, led him to pay attention to the fubject of broken tendons, and to make a feries of experiments to afcertain the mode of their union.

In the year 1768, Mr Hunter became a member of the corporation of furgeons; and in the year following, through his brother's intereft, he was elected one of the furgeons of St George's hofpital. In May 1771, his treatife on the Natural Hiftory of the Teeth was publifhed; and in July of the fame year he married Mifs Home, the eldeft daughter of Mr Home, furgeon to Burgoyne's regiment of light horfe. The expence of his purfuits had been fo great, that it was not till feveral years after his firft engagement with this lady that his affairs could be fufficiently arranged to admit of his marrying.

Though after his marriage his private practice and profeffional character advanced rapidly, and though his family began to increafe, he ftill devoted much of his time to the forming of his collection, which, as it daily became larger, was alfo attended with greater expence. The whole fuit of the beft rooms in his houfe were occupied by his preparations; and he dedicated his mornings, from funrife to eight o'clock (the hour for breakfaft), entirely to his purfuits. To thefe he added fuch parts of the day as were not engaged in attending his patients.

The knowledge he derived from his favourite ftudies he conftantly applied to the improvement of the art of furgery, and omitted no opportunity of examining morbid bodies; from which he made a collection of facts which are invaluable, as they tend to explain the real caufes of fymptoms, which during life could not be exactly afcertained, the judgment of the practitioner being too frequently mifled by theoretical opinions, and delufive fenfations of the patients.

In the practice of furgery, where cafes occurred in which the operations proved inadequate to their intention, he always inveftigated, with uncommon care, the caufes of that want of fuccefs; and in this way detected many fallacies, as well as made fome important difcoveries, in the healing art. He detected the caufe of failure, common to all the operations in ufe for the radical cure of the hydrocele, and was enabled to propofe a mode of operating, in which that event can with certainty be avoided. He afcertained, by experiments and obfervations, that expofure to atmofpherical air fimply, can neither produce nor increafe inflammation. He difcovered in the blood fo many phenomena connected with life, and not to be referred to any other caufe, that he confidered it as alive in its fluid ftate. He improved the operation for the fiftula lachrymalis, by removing a circular portion of the os unguis inftead of breaking it down with the point of a trochar. He alfo difcovered that the gaftric juice had a power when the ftomach was dead of diffolving it; and gave to the Royal Society a paper on this fubject, which is publifhed in the Philofophical Tranfactions.

In the winter 1773, he formed a plan of giving a courfe of lectures on the theory and principles of furgery, with a view of laying before the public his own opinions upon that fubject. For two winters he read his lectures *gratis* to the pupils of St George's Hofpital; and in 1775, gave a courfe for money upon the fame terms as the other teachers in the different branches of medicine and furgery. But giving lectures was always particularly unpleafant to him; fo that the defire of fubmitting his opinions to the world, and learning their general eftimation, were fcarcely fufficient to

Hunter.

overcome his natural dislike to speaking in public. He never gave the first lecture of his course without taking 30 drops of laudanum to take off the effects of his uneasiness.

Comparative anatomy may be considered as the pursuit in which Mr Hunter was constantly employed. No opportunity escaped him. In the year 1773, at the request of his friend Mr Walsh, he dissected the torpedo, and laid before the Royal Society an account of its electrical organs. A young elephant, which had been presented to the Queen by Sir Robert Barker, died, and the body was given to Dr Hunter, which afforded Mr Hunter an opportunity of examining the structure of that animal by assisting his brother in the dissection; since that time two other elephants died in the Queen's menagerie, both of which came under Mr Hunter's examination. In 1774, he published in the Philosophical Transactions an account of certain receptacles of air in birds, which communicate with the lungs, and are lodged both among the fleshy parts and hollow bones of these animals; and a paper on the Gillaroo trout, commonly called in Ireland the *Gizzardtrout*.

In 1775, several animals of that species, called the *gymnotus electricus of Surinam*, were brought alive to this country, and by their electrical properties excited very much the public attention. Mr Walsh, desirous of pursuing his investigations of animal electricity, made a number of experiments on the living animals; and to give his friend Mr Hunter an opportunity of examining them, purchased those that died. An anatomical account of their electrical organs was drawn up by Mr Hunter, and published in the Philosophical Transactions. In the same volume there is a paper of his, containing experiments on animals and vegetables respecting their power of producing heat.

In the course of his pursuits, Mr Hunter met with many parts of animals where natural appearances could not be preserved, and others, in which the minuter vessels could not be distinctly seen when kept in spirits; it was therefore necessary to have them drawn, either at the moment, or before they were put into bottles. The expence of employing professed draughtsmen, the difficulty of procuring them, and the disadvantage which they laboured under in being ignorant of the subject they were to represent, made him desirous of having an able person in his house entirely for that purpose.

With this view he engaged an ingenious young artist to live with him for ten years; his time to be wholly employed as a draughtsman, and in making anatomical preparations. This gentleman, whose name was Bell, soon became a very good practical anatomist, and from that knowledge was enabled to give a spirited and accurate resemblance of the subjects he drew, such as is rarely to be met with in representations of anatomical subjects. By his labours Mr Hunter's collection is enriched with a considerable number of very valuable drawings, and a great variety of curious and delicate anatomical preparations.

In January 1776, Mr Hunter was appointed surgeon extraordinary to his Majesty; and in the spring he gave to the Royal Society a paper on the best mode of recovering drowned persons.

In the autumn he was taken extremely ill, and the nature of his complaints made his friends, as well as himself, consider his life to be in danger. When he reflected upon his own situation, that all his fortune had been expended in his pursuits, and that his family had no provision but what should arise from the sale of his collection, he became very solicitous to give it its full value, by leaving it in a state of arrangement. This he accomplished with the assistance of Mr Bell and his brother-in-law Mr Home.

In 1778, he published the second part of his Treatise on the Teeth, in which their diseases, and the mode of treatment are considered. This rendered his work upon that subject complete. He published also in the Philosophical Transactions a paper on the Heat of Animals and Vegetables. In 1779, he published his account of the Free Martin in the Philosophical Transactions; and in 1780, he laid before the Royal Society an account of a woman who had the small-pox during pregnancy, where the disease seemed to have been communicated to the fœtus.

In 1781, he was elected a fellow of the Royal Society of Sciences and Belles Lettres at Gottenburg. And in 1782, he gave the Royal Society a paper on the Organ of Hearing in Fish. Besides the papers which he presented to that learned body, he read six Croonion lectures upon the subject of Muscular Action, for the years 1776, 1778, 1779, 1780, 1781, and 1782. In these lectures he collected all his observations upon muscles, respecting their powers and effects, and the stimuli by which they are affected; and to these he added Comparative Observations upon the moving Powers of Plants.

These lectures were not published in the Philosophical Transactions, for they were withdrawn as soon as read, not being considered by the author as complete dissertations, but rather as materials for some future publication.

It is much to be regretted (says Mr Home) that Mr Hunter was so tardy in giving his observations to the public; but such was his turn for investigation, and so extensive the scale upon which he instituted his inquiries, that he always found something more to be accomplished, and was unwilling to publish any thing which appeared to himself unfinished. His observations on the Muscular Action of the Blood-vessels were laid before the Royal Society in 1780, and yet he delayed publishing them till his Observations on the Blood and Inflammation were arranged: and they make part of the volume which was published after his death.

In 1783, he was chosen into the Royal Society of Medicine and the Royal Academy of Surgery in Paris; and the same year the lease of the house which he occupied in Jermyn street having expired, he purchased the lease of a large house on the east side of Leicester-square, and the whole lot of ground adjoining to Castle-street, on which there was another house. In the middle space between the two houses, he erected, at the expence of L.3000, a building for his collection; though, unfortunately for his family, the lease did not extend beyond 24 years.

In the building formed for the collection there was a room fifty-two feet long, by twenty-eight feet wide, lighted from the top, and having a gallery all round, for containing his preparations. Under this were two apartments; one for his lectures, and the other, with

no

no particular deſtination at firſt, but afterwards made uſe of for weekly meetings of medical friends during the winter. To this building the houſe in Caſtle-ſtreet was entirely ſubſervient; and the rooms in it were uſed for the different branches of human and comparative anatomy.

About this period Mr Hunter may be conſidered as at the height of his chirurgical career; his mind and body were both in their full vigour. His hands were capable of performing whatever was ſuggeſted by his mind; and his judgment was matured by former experience. Some inſtances of his extraordinary ſkill may very properly be mentioned.

He removed a tumor from the ſide of the head and neck of a patient at St George's Hoſpital, as large as the head to which it was attached; and by bringing the cut edges of the ſkin together, the whole was nearly healed by the firſt intention.

He diſſected out a tumor on the neck, which one of the beſt operating ſurgeons in this country had declared, rather too ſtrongly, that no one but a fool or a madman would attempt; and the patient got perfectly well.

He diſcovered a new mode of performing the operation for the popliteal aneuriſm, by taking up the femoral artery on the anterior part of the thigh without doing any thing to the tumor in the ham. The ſafety and efficacy of this mode have been confirmed by many ſubſequent trials; and it muſt be allowed to ſtand very high among the modern improvements in ſurgery.

If we conſider Mr Hunter at this period of his life, it will afford us a ſtrong picture of the turn of his mind, of his deſire to acquire knowledge, and his unremitting aſſiduity in proſecuting whatever was the object of his attention.

He was engaged in a very extenſive private practice; he was ſurgeon to St George's Hoſpital; he was giving a very long courſe of lectures in the winter; he was carrying on his inquiries in comparative anatomy; had a ſchool of practical human anatomy in his houſe; and was always employed in ſome experiments reſpecting the animal economy.

He was always ſolicitous for ſome improvement in medical education; and, with the aſſiſtance of Dr Fordyce, inſtituted a medical ſociety, which he allowed to meet in his lecture-rooms, and of which he was choſen one of the patrons. The ſociety, called the *Lyceum Medicum Londinenſe*, under his auſpices and thoſe of Dr Fordyce, has acquired conſiderable reputation, both from the numbers and merits of its members.

In the year 1786, in conſequence of the death of Mr Middleton, Mr Hunter was appointed deputy ſurgeon-general to the army. He now publiſhed his work upon the Venereal Diſeaſe, which had been long expected by the public; and, if we may judge from the rapid ſale of the firſt edition, theſe expectations have not been diſappointed. He alſo publiſhed a work entitled, Obſervations on certain Parts of the Animal Economy. In this work he has collected ſeveral of his papers inſerted in the Philoſophical Tranſactions, which related to that ſubject, having permiſſion from the preſident and council of the Royal Society to reprint them; there are alſo Obſervations upon ſome other Parts of the Animal Economy, which had not before been publiſhed. This work met with a very ready ſale.

In the year 1787, he gave a paper to the Royal Society, containing an Experiment to determine the effect of extirpating one Ovarium on the Number of Young; a paper in which the wolf, jackall, and dog, are proved to be of the ſame ſpecies; and a third upon the Anatomy of the Whale Tribe. Theſe papers procured him the honor of receiving Sir John Copley's annual gold medal, given as a mark of diſtinguiſhed abilities.

His collection, which had been the great object of his life, both as a purſuit and an amuſement, was now brought into a ſtate of arrangement; and gave him at length the ſatisfaction of ſhewing to the public a ſeries of anatomical facts formed into a ſyſtem by which the economy of animal life was illuſtrated. He ſhewed it to his friends and acquaintances twice a-year, in October to medical gentlemen, and in May to noblemen and gentlemen, who were only in town during the ſpring. This cuſtom he continued to his death.

Upon the death of Mr Adair, which happened in the year 1792, Mr Hunter was appointed inſpector general of hoſpitals, and ſurgeon general to the army. He was alſo elected a member of the Royal College of Surgeons in Ireland. In the year 1791, he was ſo much engaged in the duties of his office, as ſurgeon-general to the army, and his private practice, that he had little time to beſtow upon his ſcientifical objects; but his leiſure time, ſmall as it was, he wholly devoted to them.

In 1792, he was elected an honorary member of the Chirurgo-Phyſical Society of Edinburgh, and was choſen one of the vice-preſidents of the Veterinary College, then firſt eſtabliſhed in London. He publiſhed in the Tranſactions of the Society for the Improvement of medical and chirurgical Knowledge, of which ſociety he was one of the original members and a zealous promoter, three papers on the following ſubjects: Upon the Treatment of Inflamed Veins, on Introſuſception, and on a Mode of conveying Food into the Stomach in Caſes of Paralyſis of the Œſophagus.

He finiſhed his Obſervations on the Economy of Bees, and preſented them to the Royal Society. Theſe obſervations were made at Earl's Court, and had engaged his attention for many years; every inquiry into the economy of theſe inſects had been attended by almoſt unſurmountable difficulties; but theſe proved to him only an incitement, and the contrivances he made uſe of to bring the different operations of theſe indefatigable animals to view were almoſt without end.

Earl's Court to Mr Hunter was a retirement from the fatigues of his profeſſion; but in no reſpect a retreat from his labours; there, on the contrary, they were carried on with leſs interruption, and with an unwearied perſeverance. From the year 1772 till his death, he made it his cuſtom to ſleep there during the autumn months, coming to town only during the hours of buſineſs in the forenoon, and returning to dinner.

It was there he carried on his experiments on digeſtion, on exfoliation, on the tranſplanting of teeth into the combs of cocks, and all his other inveſtigations on the animal economy, as well in health as in diſeaſe. The common bee was not alone the ſubject of his obſervation, but the waſp, hornet, and the leſs known kinds of bees, were alſo objects of his attention. It was there he made the ſeries of preparations of the external and internal changes of the ſilk worm; alſo a ſeries of the incubation of the egg, with a very valuable ſet of drawings

Hunter.

drawings of the whole series. The growth of vegetables was also a favourite subject of inquiry, and one on which he was always engaged in making experiments.

The collection of comparative anatomy which Mr Hunter has left, and which may be considered as the great object of his life, must be allowed to be a proof of talents, assiduity, and labour, which cannot be contemplated without surprise and admiration. It remains an unequivocal test of his perseverance and abilities, and an honor to the country in whose schools he was educated, and by the patronage of which he was enabled on so extensive a scale to carry on his pursuits. In this collection we find an attempt to expose to view the gradations of Nature, from the most simple state in which life is found to exist, up to the most perfect and most complex of the animal creation—man himself.

By the powers of his art, this collector has been enabled so to expose, and preserve in spirits or in a dried state, the different parts of animal bodies intended for similar uses, that the various links of the chain of perfection are readily followed and may be clearly understood.

This collection of anatomical facts is arranged according to the subjects they are intended to illustrate, which are placed in the following order: *First*, Parts constructed for motion. *Secondly*, Parts essential to animals respecting their own internal economy. *Thirdly*, Parts superadded for purposes connected with external objects. *Fourthly*, Parts for the propagation of the species and maintainance or support of the young.

Mr Hunter was a very healthy man for the first forty years of his life; and, if we except an inflammation of his lungs in the year 1759, occasioned most probably by his attention to anatomical pursuits, he had no complaint of any consequence during that period. In the spring of 1769, in his forty-first year, he had a regular fit of the gout, which returned the three following springs, but not the fourth; and in the spring of 1773, having met with something which very forcibly affected his mind, he was attacked at ten o'clock in the forenoon with a pain in the stomach, attended with all the symptoms of *angina pectoris*. In the life of him prefixed to his *Treatise on the Blood, Inflammation, and Gun-Shot Wounds*, the reader will find one of the most complete histories of that disease upon record. Suffice it, in this place, to say, that for twenty years he was subject to frequent and severe attacks of it, which however did not, till a short time before his death, either impair his judgment or render him incapable of performing operations in surgery. "In autumn 1790 (says Mr Home), and in the spring and autumn 1791, he had more severe attacks than during the other periods of the year, but of not more than a few hours duration: in the beginning of October 1792, one, at which I was present, was so violent that I thought he would have died. On October the 16th, 1793, when in his usual state of health, he went to St George's Hospital, and meeting with some things which irritated his mind, and not being perfectly master of the circumstances, he withheld his sentiments; in which state of restraint he went into the next room, and turning round to Dr Robertson, one of the physicians of the hospital, he gave a deep groan and dropt down dead; being then in his 65th year, the same age at which his brother Dr Hunter had died."

Hunter, || Hunter fort.

It is a curious circumstance, that the first attack of these complaints was produced by an affection of the mind, and every future return of any consequence arose from the same cause; and although bodily exercise, or distention of the stomach, brought on slighter affections, it still required the mind to be affected to render them severe; and as his mind was irritated by trifles, these produced the most violent effects on the disease. His coachman being beyond his time, or a servant not attending to his directions, brought on the spasms, while a real misfortune produced no effect.

Mr Hunter was of a short stature, uncommonly strong and active, very compactly made, and capable of great bodily exertion. His countenance was animated, open, and in the latter part of his life deeply impressed with thoughtfulness. When his print was shewn to Lavater, he said, "That man thinks for himself." In his youth he was cheerful in his disposition, and entered into youthful follies like others of the same age; but wine never agreed with his stomach; so that after some time he left it off altogether, and for the last twenty years drank nothing but water.

His temper was very warm and impatient, readily provoked, and, when irritated, not easily soothed. His disposition was candid, and free from reserve, even to a fault. He hated deceit; and as he was above every kind of artifice, he detested it in others, and too openly avowed his sentiments. His mind was uncommonly active; it was naturally formed for investigation, and that turn displayed itself on the most trivial occasions, and always with mathematical exactness. What is curious, it fatigued him to be long in a mixed company which did not admit of connected conversation; more particularly during the last ten years of his life.

He required less relaxation than most other men; seldom sleeping more than four hours in the night, but almost always nearly an hour after dinner; this, probably, arose from the natural turn of his mind being so much adapted to his own occupations, that they were in reality his amusement, and therefore did not fatigue.

In private practice he was liberal, scrupulously honest in saying what was really his opinion of the case, and ready upon all occasions to acknowledge his ignorance, whenever there was any thing which he did not understand.

In conversation, he spoke too freely, and sometimes harshly, of his contemporaries; but if he did not do justice to their undoubted merits, it arose not from envy, but from his thorough conviction that surgery was as yet in its infancy, and he himself a novice in his own art; and his anxiety to have it carried to perfection, made him think meanly and ill of every one whose exertions in that respect did not equal his own.

HUNTER FORT, 21 miles west of Schenectady, on the south side of Mohawk river, at the mouth of Schohary Creek, over which a bridge is about to be built. Here is an old church built in the reign of queen Ann, and 3 or 4 houses. At this place was the Old Mohawk town, which was abandoned by that nation as late as the spring of 1780. These Indians had made considerable advances in civilization—could generally speak the English language, and numbers of them made profession of their faith in the Christian religion. In the church which is now standing, they used to attend public worship in the Episcopal form. These Indians are

are now settled, a part of them on Grand river, a northern water of Lake Erie, and a part of them in another part of Upper Canada. None of this nation now remain in the United States. The father of the only remaining family was drowned in 1788.—*Morse.*

HUNTERDON *County*, in New-Jersey, is bounded N. by that of Morris, E. by Somerset, S. E. by Burlington, S. W. and W. by Delaware river, which separates it from the State of Pennsylvania, and N. W. by Sussex county. It is about 40 miles long, and 32 broad, is divided into 10 townships, and contains 20,253 inhabitants, including 1,301 slaves. On the top of Musconetcong mountain in this county, is a noted medicinal spring, much resorted to. It issues from the side of a mountain into an artificial reservoir, for the accommodation of those who wish to bathe in, as well as to drink, the waters. It is a strong chalybeate. Trenton is the chief town.—*ib.*

HUNTERSTOWN, a village of Pennsylvania, situated in York county, 25 miles W. by S. of York-Town. —*ib.*

HUNTING-CREEK, in Virginia, runs east into Patowmak river, at the south corner of the territory of Columbia.—*ib.*

HUNTING-CREEK-TOWN, a village in the northern part of Dorchester county, Maryland; 14 miles N. N. W. of Vienna, 16 S. by W. of Denton, and 18 N. E. of Cambridge.—*ib.*

HUNTINGDON, an extensive and mountainous county in Pennsylvania, bounded N. and N. W. by Lycoming county, E. and N. E. by Mifflin, S. E. by Franklin, S. and S. W. by Bedford and Somerset, and west by Westmoreland. It is about 75 miles long and 39 broad; contains 1,432,960 acres of land, divided into 7 townships, which contain 7,565 inhabitants. Limestone, iron ore and lead are found here. A furnace and two forges manufacture considerable quantities of pig and bar iron, and hollow ware; large works have also been established for manufacturing of lead. Chief town, Huntingdon.—*ib.*

HUNTINGDON, the capital of the above county, situated on the N. E. side of Juniatta river, and at the mouth of Standing Stone creek, 50 miles from the mouth of Juniatta, contains about 90 houses, a court-house, and gaol. It is about 23 miles W. S. W. of Lewis Town, and 184 W. N. W. of Philadelphia.—*ib.*

HUNTINGDON, a post-town on the north side of Long Island, New-York, situated at the head of a bay in Suffolk county, which sets up south from the sound, contains about 70 houses, a Presbyterian and Episcopal church. It is 38 miles E. by N. of New-York city. It is opposite to Norwalk in Connecticut, and contains 3,260 inhabitants; of these, 552 are electors, 213 slaves.—*ib.*

HUNTINGDON, a township in York county, Pennsylvania.—*ib.*

HUNTINGTON, a township in Fairfield county, Connecticut, separated from Derby on the north-east by Stratford river.—*ib.*

HUNTING-TOWN, a village on the west side of Chesapeak bay in Maryland, situated on the S. E. side of Hunting Creek, in Calvert county, 3 miles N. by W. of Prince Frederick, and 22 E. N. E. of Port Tobacco.—*ib.*

HUNTSBURG, a township in Franklin county, in Vermont. It is situated on the Canada line, having 46 inhabitants.—*ib.*

HUNTSVILLE, a post-town in North-Carolina, 10 miles from Bethania, and 16 from Rockford.—*ib.*

HURLEY, a township in Ulster county, New-York, containing 847 inhabitants; of whom 116 are electors, and 245 slaves. The compact part contains about 30 houses, situated on Esopus Kill, about 5 miles from the west bank of Hudson's river, and 100 north of New-York. The lands around it are low and fertile, but infested with wild onions.—*ib.*

HURON, one of the five principal northern lakes. It lies between 43° 30′, and 47° 30′ N. lat. and between 80° 45′, and 84° 45′ W. long. and is reckoned to be upwards of 1000 miles in circumference. The fish are of the same kind as in Lake Superior, and it communicates with that lake through the straits of St. Marie on the N. W. with Michigan on the W. and with Erie on the S. It is of a triangular shape, and on the S. W. part is *Saguinum* or Sagana bay, 80 miles in length, and about 18 or 20 in breadth; the other most remarkable bay is *Thunder Bay*. On the banks of the lake are found amazing quantities of sand cherries. The land bordering on the western shore of the lake is greatly inferior in quality to that on Lake Erie. It is mixed with sand and small stones, and is principally covered with pines, birch, and some oaks; but a little distance from the lake the soil is very luxuriant. Twenty years ago, part of the Indian nations, called Chepaways and Ottawas, who inhabited round Saguinum bay and on the banks of the lake could furnish 200 warriors; and those of the latter nation, who lived on the E. side of Lake Michigan, 21 miles from Michillimakkinack could furnish 200 warriors.—*ib.*

HURON, a small river of the N. W. territory, which, after a course of 38 miles, falls into Lake St Clair from the N. W. Gnadenhuetten lies on this river. Also the name of another small river in the same territory, which runs N. eastward into Lake Erie, 40 miles westward of Cayahoga, and 15 S. E. of the mouth of Sandusky Lake.—*ib.*

HURTERS, in fortification, denote pieces of timber, about six inches square, placed at the lower end of the platform, next to the parapet, to prevent the wheels of the gun-carriages from damaging the parapet.

HYDE, a maritime county in Newbern district, North-Carolina; bounded E. by the ocean, W. by Beaufort county, N. by Tyrrel, and S. by Carteret. It contains 4120 inhabitants, of whom 1048 are slaves.—*Morse.*

HYCO-OTEE, or *Hycoo*, a small river which empties into the Dan, about 4 miles above the mouth of Staunton river.—*ib.*

HYDESPARK, a township in Orleans county, in Vermont, containing 43 inhabitants. It is 25 miles S. of the Canada line, and 126 north by east of Bennington.—*ib.*

HYDROGRAPHICAL CHARTS or MAPS, more usually called sea-charts, are projections of some part of the sea, or coast, for the use of navigation. In these are laid down all the rhumbs or points of the compass, the meridians, parallels, &c. with the coasts, capes, islands, rocks, shoals, shallows, &c. in their proper places, and proportions.

Hydrometer, || Hydrus.

HYDROMETER, is an inſtrument, of which ſo much has been ſaid in the *Encycl.* under that title, and in the article Specific *Gravity*, that we certainly ſhould not again introduce it in this place, but to guard our readers againſt error, when ſtudying the works of the French chemiſts. Theſe gentlemen, who are ſo ſtrongly attached to every thing which is new, as to believe that their anceſtors have for ages been wandering in the mazes of ignorance, refer very frequently to the *peſe-liqueur* of Baumé; and as that inſtrument has never been generally uſed in this country, it becomes our duty to deſcribe its conſtruction.

Inſtead of adopting the ſimple method of immediate numerical reference to the denſity of water expreſſed by unity, as is done in all modern tables of ſpecific gravity, he had recourſe to a proceſs ſimilar to that of graduating the ſtems of thermometers from two fixed points. The firſt of theſe points was obtained by immerſing his inſtrument, which is the common areometer, conſiſting of a ball, ſtem, and counterpoiſe, in pure water. At that point of the ſtem which was interſected by the ſurface of the fluid, he marked *zero*, or the commencement of his graduations. In the next place, he provided a number of ſolutions of pure dry common ſalt in water: theſe ſolutions contained reſpectively one, two, three, four, &c. pounds of the ſalt; and in each ſolution the quantity of water was ſuch, as to make up the weight equal to one hundred pounds in the whole; ſo that in the ſolution containing one pound of ſalt, there were ninety-nine pounds of water; in the ſolution containing two pounds of ſalt, there were ninety-eight pounds of water, and ſo of the reſt. The inſtrument was then plunged in the firſt ſolution, in which of courſe it floated with a larger portion of the ſtem above the fluid, than when pure water was uſed. The fluid, by the interſection of its ſurface upon the ſtem, indicated the place for marking his firſt degree; the ſame operation repeated, with the fluid containing two pounds of ſalt, indicated the mark for the ſecond degree; the ſolution of three pounds afforded the third degree; and in this manner his enumeration was carried as far as fifteen degrees. The firſt fifteen degrees afterwards, applied with the compaſſes repeatedly along the ſtem, ſerved to extend the graduation as far as eighty degrees, if required.

This inſtrument, which is applicable to the admeaſurement of denſities exceeding that of pure water, is commonly diſtinguiſhed by the name of the *Hydrometer for ſalts*.

The hydrometer for ſpirits is conſtructed upon the ſame principle; but in this the counterpoiſe is ſo adjuſted, that moſt part of the ſtem riſes above the fluid when immerſed in pure water, and the graduations to expreſs inferior denſities are continued upwards. A ſolution of ten parts by weight of ſalt in ninety parts of pure water, affords the firſt point, or zero, upon the ſtem; and the mark indicated by pure water is called the tenth degree; whence, by equal diviſions, the remaining degrees are continued upwards upon the ſtem as far as the fiftieth degree.

Theſe experiments, in both caſes, are made at the tenth degree of Reaumur, which anſwers very nearly to fifty-five of Fahrenheit.

HYDRUS, or Water Serpent, one of the new ſouthern conſtellations, including only ten ſtars.

Hygrometer.

HYGROMETER, is an inſtrument of ſo much importance to the meteorologiſt, that it becomes us to give ſome account of every improvement of it which has fallen under our notice. In the *Encyclopædia*, the principles upon which hygrometers are conſtructed have been clearly ſtated, and the defects of each kind of hygrometer pointed out.

Inſtead of hairs or cat-gut, of which hygrometers of the firſt kind are commonly made, Caſſebois, a benedictine monk at Mentz, propoſed to make ſuch hygrometers of the gut of a ſilk worm. When that inſect is ready to ſpin, there are found in it two veſſels proceeding from the head to the ſtomach, to which they adhere, and then bend towards the back, where they form a great many folds. The part of theſe veſſels next the ſtomach is of a cylindric form, and about a line in diameter. Theſe veſſels contain a gummy ſort of matter from which the worm ſpins its ſilk; and, though they are exceedingly tender, means have been deviſed to extract them from the inſect, and to prepare them for the above purpoſe. When the worm is about to ſpin, it is thrown into vinegar, and ſuffered to remain there twenty-four hours; during which time the vinegar is abſorbed into the body of the inſect, and coagulates its juices. The worm being then opened, both the veſſels, which have now acquired ſtrength, are extracted; and, on account of their pliability, are capable of conſiderable extenſion. That they may not, however, become too weak, they are ſtretched only to the length of about fifteen or twenty inches. It is obvious that they muſt be kept ſufficiently extended till they are completely dry. Before they attain to that ſtate, they muſt be freed, by means of the nail of the finger, from a ſlimy ſubſtance which adheres to them. Such a thread will ſuſtain a weight of ſix pounds without breaking, and may be uſed for an hygrometer in the ſame manner as cat-gut; but we confeſs that we do not clearly perceive its ſuperiority.

To an improvement of the hygrometer conſtructed on the third principle, ſtated in the *Encyclopædia*, M. Hochheimer was led in the following manner:

Mr Lowitz found at Dmitriewſk in Aſtracan, on the banks of the Wolga, a thin bluiſh kind of ſlate which attracted moiſture remarkably ſoon, but again ſuffered it as ſoon to eſcape. A plate of this ſlate weighed, when brought to a red heat, 175 grains, and, when ſaturated with water, 247: it had therefore imbibed, between complete dryneſs and the point of complete moiſture, 72 grains of water. Lowitz ſuſpended a round thin plate of this ſlate at the end of a very delicate balance, faſtened within a wooden frame, and ſuſpended at the other arm a chain of ſilver wire, the end of which was made faſt to a ſliding nut that moved up and down in a ſmall groove on the edge of one ſide of the frame. He determined, by trial, the poſition of the nut when the balance was in equilibrio and when it had ten degrees of over-weight, and divided the ſpace between theſe two points into ten equal parts, adding ſuch a number more of theſe parts as might be neceſſary. When the ſtone was ſuſpended from the one arm of the balance, and at the other a weight equal to 175 grains, or the weight of the ſtone when perfectly dry, the nut in the groove ſhewed the exceſs of weight in grains when it and the chain were ſo adjuſted that the balance ſtood in equilibrio. A particular apparatus on the

Hygrometer.

the same principles as a vernier, applied to the nut, shewed the excess of weight to ten parts of a grain. Lowitz remarked that this hygrometer in continued wet weather gave a moisture of more than 55 grains, and in a continued heat of 113 degrees of Fahrenheit only 1½ degree of moisture.

The hygrometer thus invented by Lowitz was, however, attended with this fault, that it never threw off the moisture in the same degree as the atmosphere became drier. It was also sometimes very deceitful, and announced moisture when it ought to have indicated that dryness had again begun to take place in the atmosphere. To avoid these inconveniencies, M. Hochheimer proposes the following method:

7. Take a square bar of steel about two lines in thickness, and from ten to twelve inches in length, and form it into a kind of balance, one arm of which ends in a screw. On this screw let there be screwed a leaden bullet of a proper weight, instead of the common weights that are suspended. 2. Take a glass plate about ten inches long, and seven inches in breadth, destroy its polish on both sides, free it from all moisture by rubbing it over with warm ashes, suspend it at the other end of the balance, and bring the balance into equilibrium by screwing up or down the leaden bullet. 3. Mark now the place to which the leaden bullet is brought by the screw, as accurately as possible, for the point of the greatest dryness. 4. Then take away the glass plate from the balance, dip it completely in water, give it a shake that the drops may run off from it, and wipe them carefully from the edge. 5. Apply the glass plate thus moistened again to the balance, and bring the latter into equilibrium by screwing the leaden bullet. Mark then the place at which the bullet stands as the highest degree of moisture. 6. This apparatus is to be suspended in a small box of well dried wood, sufficiently large to suffer the glass-plate to move up and down. An opening must be made in the lid, exactly of such a size as to allow the tongue of the balance to move freely. Parallel to the tongue apply a graduated circle, divided into a number of degrees at pleasure from the highest point of dryness to the highest degree of moisture. The box must be pierced with small holes on all the four sides, to give a free passage to the air; and to prevent moisture from penetrating into the wood by rain, when it may be requisite to expose it at a window, it must either be lackered or painted. To save it at all times from rain, it may be covered, however, with a sort of roof fitted to it in the most convenient manner. But all these external appendages may be improved or altered as may be found necessary.

Hyperbola, || Hypotrachelion.

HYPEBOLA Deficient, is a curve having only one asymptote, though two hyperbolic legs running out infinitely by the side of the asymptote, but contrary ways.

HYPOTRACHELION, in Architecture, is used for a little frize in the Tuscan and Doric capital, between the astragal and annulets; called also the colerin and gorgerin. The word is applied by some authors in a more general sense, to the neck of any column, or that part of its capital below the astragal.

I.

Jacobins.

JACOBINS, in the language of the present day, is the name assumed, at the beginning of the French revolution, by a party in Paris, which was outrageously democratical, and fanatically impious. This party, which consisted of members of the National Assembly, and of others maintaining the same opinions and pursuing the same objects, formed itself into a club, and held its meetings in the hall belonging to the Jacobin friars, where measures were secretly concerted for exciting insurrections, and over-awing at once the legislature and the king. The name of *Jacobin*, though it was derived from the hall where the club first met, has since been extended to all who are enemies to monarchy, aristocracy, and the Christian religion; and who would have every man to be his own priest and his own lawgiver. Hence it is, that we have Jacobins in other countries as well as in France.

Of the proceedings of the French Jacobins, some account has been given, in the *Encyclopædia*, under the title Revolution, and the subject will be resumed in this *Supplement* under the same title. The purpose of the present article is to trace the principles of the sect from their source; for these principles are not of yesterday.

"At its very first appearance, (says the Abbé Barruel), this sect counted 300,000 adepts; and it was supported by two millions of men, scattered through France, armed with torches and pikes, and all the firebrands of the revolution." Such a wide spread conspiracy could not be formed in an instant; and indeed this able writer has completely proved, that this sect, with all its conspiracies, is in itself no other than "the coalition of a triple sect, of a triple conspiracy, in which, long before the revolution, the overthrow of the altar, the ruin of the throne, and the dissolution of all civil society, had been debated and determined."

It is known to every scholar that there have been in all ages and countries men of letters and pretenders to letters who have endeavoured to signalize themselves individually by writing against the religion of their country; but it was reserved for the philosophists (A) of France to enter into a combination for the express purpose

(A) This term was invented by Abbé Barruel, and we have adopted it, as denoting something very different from the meaning of the word *philosopher*.

Jacobins. purpose of eradicating from the human heart every religious sentiment. The man to whom this idea first occurred was Voltaire; who, daring to be jealous of his God, and being weary, as he said himself, of hearing people repeat that twelve men were sufficient to establish Christianity, resolved to prove that one might be sufficient to overthrow it. Full of this project, he swore, before the year 1730, to dedicate his life to its accomplishment; and for some time he flattered himself that he should enjoy alone the glory of destroying the Christian religion. He found, however, that associates would be necessary; and from the numerous tribe of his admirers and disciples, he chose D'Alembert and Diderot as the most proper persons to cooperate with him in his designs. How admirably they were qualified to act the part assigned them, may be conceived from the life of DIDEROT in this *Supplement*. But Voltaire was not satisfied with their aid alone.

He contrived to embark in the same cause Frederic II. of Prussia, who wished to be thought a philosopher, and who of course deemed it expedient to talk and write against a religion which he had never studied, and into the evidence of which he had probably never deigned to enquire. This royal adept was one of the most zealous of Voltaire's coadjutors, till he discovered that the philosophists were waging war with the throne as well as with the altar. This indeed was not originally Voltaire's intention. He was vain; he loved to be caressed by the great; and, in one word, he was, from natural disposition, an aristocrate and admirer of royalty: But when he found that almost every sovereign but Frederick disapproved of his impious projects as soon *as he perceived their issue*, he determined to oppose all the governments on earth, rather than forfeit the glory with which he had flattered himself, of vanquishing Christ and his apostles in the field of controversy.

He now set himself, with D'Alembert and Diderot, to excite universal discontent with the established order of things. This was an employment entirely suited to their disposition; for not being in any sense *great* themselves (B), they wished to pull all men down to their own level. How effectually they contrived to convert the *Encyclopædie* into an engine to serve their purposes, has been shown already; but it was not their only nor their most powerful engine; they formed secret societies, assumed new names, and employed an enigmatical language. Thus, Frederic is called *Luc*; D'Alembert, *Protagoras*, and sometimes *Bertrand*; Voltaire, *Raton*; and Diderot, *Platon*, or its anagram *Tonpla*; while the general term for the conspirators is *Cacouac*. In their secret meetings they professed to celebrate the mysteries of *Mythra*; and their great object, as they professed to one another, was to confound the *wretch*, meaning J— C—. Voltaire proposed to establish a colony of philosophists at Cleves, who, protected by the king of Prussia, might publish their opinions without dread or danger; and Frederic was disposed to take them under his protection, till he discovered that their opinions were anarchical as well as impious, when he threw them off, and even wrote against them. Jacobins.

They contrived, however, to engage the ministers of the court of France in their favour, by pretending to have nothing in view but the enlargement of science, in works which spoke indeed respectfully of revelation, while every discovery which they brought forward was meant to undermine its very foundation. When the throne was to be attacked, and even when barefaced atheism was to be promulgated, a number of impious and licentious pamphlets were dispersed, for some time none knew how, from a secret society formed at the Hotel d'Holbach at Paris. These were sold for trifles, or distributed *gratis* to schoolmasters, and others who were likely to circulate their contents. D'Alembert, Diderot, and Condorcet, who was now associated with the other conspirators, flattered the ambition of every man among the great, and especially of the Duke d'Orleans, the richest subject in Europe, and a prince of the blood of France. The first and the last of these three adepts, had, by their mathematical knowledge, got such an ascendency in the Royal Academy of Sciences, that they could admit or exclude candidates as they knew them to be friendly or inimical to the projects of the conspirators; and they had contrived, by matchless address and unwearied perseverance, to fill almost all the seminaries of education with men of their own principles.

Thus was the public mind in France completely corrupted, when the mason lodges, over which the infamous Orleans presided, were visited by a delegation from the German illuminati; and nothing more was necessary to produce the sect of *Jacobins*, by whose intrigues and influence, France, as M. Barruel expresses himself, has become a prey to every crime. It was by the machinations of this sect that its soil was stained with the blood of its pontiffs and priests, its rich men and nobles; with the blood of every class of its citizens, with no regard to rank, age or sex. These disciples of Voltaire were the men who, after having made the unfortunate Louis, his queen and sister, drink to the very dregs, the cup of outrage and ignominy during a long confinement, solemnly murdered them on a scaffold, proudly menacing all the sovereigns of the earth with a similar fate. Yet think not, indignant reader, that the ways of Providence are unequal. The nations of Europe were ripe for chastisement, and that chastisement these villains were employed to inflict: but their own punishment did not linger. Voltaire died in agonies of desponding remorse, which can be exceeded only by the torments of the damned. There is reason to believe that the end of D'Alembert and Diderot very much resembled that of their leader; while the more hardened adept, Condorcet, became his own executioner; and the other chiefs of the rebellion have reciprocally inflicted vengeance on each other, every alteration of the French constitution (and these alterations have been many) being followed by the execution of those by whom the government was previously administered.

(B) We do not by this mean to insinuate that D'Alembert was not a man of science. He was perhaps the only man of science in that gang; but he was a master of no science but mathematics; and his birth being obscure, if not spurious, and abstract mathematics not furnishing ready access to the great, his ideas, when compared with Voltaire's, were groveling, and (as M. Barruel says) he was afraid to be seen.

JAGHIRE, assignment made in Bengal by an Imperial grant upon the revenue of any district, to defray civil or military charges, pensions, gratuities, &c.

JAGHIREDER, the holder of a Jaghire.

St. JAGO, the largest and most populous of the Cape de Verde islands, of which some account has been given in the *Encyclopædia*, is represented by Sir George Staunton as liable to long and excessive droughts, for which no philosophical cause can be assigned. When the embassy to China touched at it in the latter end of 1792, it was in a state of absolute famine. Little or no rain had fallen for about three years before. The rivers were almost all entirely dry. The surface of the earth was, in general, naked of any herbage. The greatest part of the cattle had perished, not less through drought than want of food. Of the inhabitants, many had migrated, and many were famished to death. Nor was this calamity peculiar to St Jago. All the islands of Cape de Verde were said to have experienced the same long drought, and to be consequently in a state of similar desolation. Yet the frequent showers which were observed by the first navigators who touched at St Jago, induced them to give to the island the name of *Pluvialis*; and no change had been observed in the steady current of wind, blowing from the east, which is common to tropical climates.

"What were the uncommon circumstances (says Sir George) that took place in the atmosphere of that part of Africa to which the Cape de Verde Islands lie contiguous, or in the vast expanse of continent extending to the east behind it, and from which this direful effect must have proceeded (as they happened where no man of science existed to observe or to record them), will therefore remain unknown. Nor is theory bold enough to supply the place of observation. Whatever was the cause which thus arrested the bountiful hand of Nature, by drawing away the sources of fertility, it was observable, that some few trees and plants persevered to flourish with a luxuriance, indicating that they still could extract from the arid earth whatever portion of humidity it was necessary to derive from thence for the purpose of vegetable life, though it was denied to others."

Beside the trees of the palm kind, which are often found verdant amidst burning sands, nothing, for example, could be more rich in flavour, or abound more with milky, though corrosive juice, than the asclepias gigantea (see Asclepias, *Encycl.*), growing plentifully, about several feet high, without culture, indeed, but undisturbed, it being of no avail to cut it down in favour of plants that would be useful, but required the aid of more moisture from the atmosphere. The jatropha curcas, or physic nut tree, which the French West Indians, with some propriety, call *bois immortel*, and plant, on that account, in the boundaries of their estates, appeared as if its perpetuity was not to be affected by any drought. Some indigo plants were still cultivated with success in shaded vales, together with a few cotton shrubs. Throughout the country some of those species of the mimosa, or sensitive plant, which grow into the size of trees, were most common, and did not appear to languish. In particular spots the annona, or sugar apple tree was in perfect verdure. The borassus, or great fan palm, lifted, in a few places, its lofty head and spreading leaves, with undiminished beauty. In a bottom, about a mile and a half behind the town of Praya, was still growing, in a healthy state, what may be called for size a phenomenon in vegetation, a tree known to botanists by the name of adansonia, and in English called *monkey bread tree*. The natives of St Jago call it *kabisera*; others baobab. Its trunk measured at the base no less than 56 feet in girth; but it soon divided into two great branches, one rising perpendicularly, and measuring 42 feet in circumference. That of the other was about 26. By it stood another of the same species, whose single trunk of 38 feet girth, attracted little notice from the vicinity of its huge companion.

But the annual produce of agriculture was scarcely to be found. The plains and fields, formerly productive of corn, sugar-canes, or plantains, nourished by regular falls of rain, now bore little semblance of vegetation. Yet in the small number of plants which survived the drought, were some which, from the specimens sent to Europe, were found to have been hitherto unknown. Vegetation quickly, indeed, revived wherever, through the soil, any moisture could be conveyed.

Sir George represents Praya, the residence of the Portuguese Viceroy, as a hamlet rather than a town. It consists of about 100 very small dwellings, one story high, scattered on each side of the plain, which extended near a mile in length, and about the third of a mile in breadth; and fell off, all around, to the neighbouring valleys and to the sea. Not being commanded by any neighbouring eminence, it was a situation capable of defence; the fort, however, or battery, was almost in ruins; and the few guns mounted on it were mostly honey-combed, and placed on carriages which scarcely held together.

A party belonging to the embassy crossed the country to the ruins of St Jago, the former capital of the island, situated in the bottom of a vale, through which ran a stream then both small and sluggish. On each side of that stream are the remains of dwellings of considerable solidity and size; and the fragments of glass lustres, still hanging from the ceilings of some of the principal apartments, denote the elegance or riches that were once displayed in this now deserted place. Not above half a dozen families remain in it at present; the rest abandoned it, or perished. Here was still, however, an attempt at a slight manufactory of striped cotton slips, the same as are made in the other parts of the island, for the use of the Africans on the main, who pay for them in slaves, elephants teeth, and that gum which is generally called arabic.

Amidst the ruins of St Jago the party found a Portuguese, to whom one of them was recommended, and who received them with the most cordial hospitality in his house, and treated them with every species of tropical fruits from his garden, lying on each side the river.

He had been a navigator; and informed them that the isle of Brava, one of the Cape de Verde's, was a fitter and safer place for ships to call at for water and provisions than the island of St Jago; that it had three harbours; one called Puerto Furno on the east side of the island, from which vessels must warp, or be towed out by boats; the Puerto Fajendago to the west; and the Puerto Ferreo to the south, which was the best for large ships, and into which runs a small river. In another of the Cape de Verde islands, called San Vicenté, he observed that there was also a large harbour on the north

north end, but that fresh water was at some distance from it: and there was likewise a good port at Bonavista. This information of the harbours in the isle of Brava was confirmed by accounts given by others to Sir Erasmus Gower, who recommends to make a trial of them.

JALOFFS, or Yaloffs, are an active, powerful, and warlike people, inhabiting great part of that tract of Africa which lies between the Senegal and the Mandingo states on the Gambia (See Mandingoes in this *Supplement*). Their noses, says Mr Park, are not so much depressed, nor their lips so protuberant, as those of the generality of Africans; and though their skin is of the deepest black, they are considered by the white traders as the most sightly Negroes in that part of the continent where they live. They are divided into several independent states or kingdoms, which are frequently at war with their neighbours or with each other. In their manners, superstitions, and government, they have a greater resemblance to the Mandingoes than to any other nation; but excel them in the manufacture of cotton cloth, spinning the wool to a finer thread, weaving it in a broader loom, and dyeing it of a better colour. They make very good soap, by boiling ground nuts in water, and then adding a ley of wood ashes. They likewise manufacture excellent iron, which they carry to Bondou to barter for salt. Their language is said to be copious and significant, and is often learned by Europeans trading to Senegal. From the names of their numerals, as given by Mr Park, it would appear that their numeration proceeds by *fives*, as ours does by *tens*.

Our author relates the event of a religious war, which, as it displays a generosity of character very uncommon among savages, will afford pleasure to the minds of many of our readers. Almami Abdulkader, sovereign of a Mahomedan kingdom called Foota Torra, sent to Damel, a king of the Jaloffs, an imperious message, commanding him and his subjects to embrace instantly the faith of the prophet. The ambassador having got admission to the presence of Damel, ordered some Bushreens (*i. e.* Mahomedan Negroes) who accompanied him, to present the emblems of his mission. Two knives were accordingly laid before the Jaloff prince, and the ambassador explained himself as follows: "With this knife (said he) Abdulkader will condescend to shave the head of Damel, if Damel will embrace the Mahomedan faith; and with this other knife Abdulkader will cut the throat of Damel, if Damel refuses to embrace it: Take your choice."—Damel coolly told the ambassador that he had no choice to make: he neither chose to have his head shaved, nor his throat cut. And with this answer the ambassador was civilly dismissed.

Abdulkader took his measures accordingly; and with a powerful army invaded Damel's country. The inhabitants of the towns and villages filled up their wells, destroyed their provisions, carried off their effects, and abandoned their dwellings, as he approached. By this means he was led on from place to place, until he had advanced three days journey into the country of the Jaloffs. He had, indeed, met with no opposition; but his army had suffered so much from the scarcity of water, that several of his men died by the way. This induced him to direct his march towards a watering place in the woods, where his men, having quenched their thirst, and being overcome with fatigue, lay down carelessly to sleep among the bushes. In this situation they were attacked by Damel before day-break, and completely routed. Many of them were trampled to death as they lay asleep by the Jaloffs horses; others were killed in attempting to make their escape; and a still greater number were taken prisoners. Among the latter was Abdulkader himself. This ambitious or rather frantic prince, who, but a month before, had sent the threatening message to Damel, was now himself led into his presence as a miserable captive. The behaviour of Damel, on this occasion, is never mentioned by the singing men* but in terms of the highest approbation; and it was, indeed, so extraordinary in an African prince, that the reader may find it difficult to give credit to the recital. When his royal prisoner was brought before him in irons, and thrown upon the ground, the magnanimous Damel, instead of setting his foot upon his neck, and stabbing him with his spear, according to the custom in such cases, addressed him as follows: "Abdulkader, answer me this question. If the chance of war had placed me in your situation, and you in mine, how would you have treated me?" "I would have thrust my spear into your heart (returned Abdulkader with great firmness); and I know that a similar fate awaits me." "Not so (said Damel); my spear is indeed red with the blood of your subjects killed in battle, and I could now give it a deeper stain, by dipping it in your own; but this would not build up my towns, nor bring to life the thousands who fell in the woods. I will not therefore kill you in cold blood, but I will retain you as my slave, until I perceive that your presence in your own kingdom will be no longer dangerous to your neighbours; and then I will consider of the proper way of disposing of you." Abdulkader was accordingly retained, and worked as a slave for three months; at the end of which period, Damel listened to the solicitations of the inhabitants of Foota Torra, and restored to them their king. Strange as this story may appear, Mr Park has no doubt of the truth of it. It was told to him at Malacotta by the Negroes; it was afterwards related to him by the Europeans on the Gambia; by some of the French at Goree; and confirmed by nine slaves, who were taken prisoners along with Abdulkader by the watering place in the woods, and carried in the same ship with him to the West Indies.—Such generosity as this reflects honour on human nature.

* *The historians of the country.*

JARRA, is a town of considerable extent in the Moorish kingdom of Ludamar in Africa. The houses are built of clay and stone intermixed, a kind of wall very common in many parts of Scotland, where clay is made to supply the place of mortar. The greater part of the inhabitants of Jarra are Negroes from the borders of the southern states, who prefer, says Mr Park, a precarious protection under the Moors, which they purchase by a tribute, to the being continually exposed to their predatory hostilities. The tribute which they pay is considerable; and they manifest the most unlimited obedience and submission to their Moorish superiors; by whom they are, in return, treated with the utmost indignity and contempt. The Moors in this, and the other states adjoining the country of the Negroes, resemble in their persons the Mulattoes of the West

West Indies, and seem to be a mixed race between the Moors, properly so called, of the north, and the Negroes of the south; possessing many of the worst qualities of both nations. Jarra is situated in 15° 5′ N. Lat. and 6° 48′ E. Long.

IATA, a bay on the coast of Chili.—*Morse.*

IBBERVILLE, a river or rather a sort of natural canal, of W. Florida, which, when the Mississippi overflows, and is high enough to run into it, (which is generally in the months of May, June, and July) forms a communication for vessels drawing three or four feet, from the Mississippi to the gulf of Mexico, eastward, through the lakes Mauripas and Pontchartrain. This canal, which has been dignified with the name of river, is dry all the rest of the year. It is a mile below a village of Alabama Indians, 35 miles from the settlements of Point Coupeé, 99 W. by N. of New-Orleans, 204 N. W. of the Balize, and 270 W. of Pensacola, by the above lakes. It receives the river Amit or Amite, from the northward, which is navigable for batteaux to a considerable distance.—*ib.*

IBIS. Under the generic name TANTALUS (*Encycl.*), we have described, after Mr Bruce, a bird which he found in Abyssinia, and concluded to be the sacred ibis of ancient Egypt. M. Vaillant, during his last travels in Africa, found, in some lakes near the elephants river, a bird very different from Mr Bruce's, which he considered as belonging to the same species; and which he describes thus: It is three feet in height. Its head and throat, which are extremely bare, are covered with a skin of the brightest red, terminated by a band of a beautiful orange, which separates the naked part from that covered with feathers. The upper part of the wings, having broad stripes of a fine violet colour, agreeably shaded, is bordered by a white band of feathers, the thick and silky beards of which, separated from each other, have a perfect resemblance to a rich fringe. The quills of the wings and tail are of a greenish black, which, as it receives the light in a more or less oblique direction, assumes the appearance of violet or purple. The rest of the plumage is of a beautiful white. The bill, which is long and somewhat crooked, is yellow; as are the feet. This bird belongs to the genus of the ibis, of which we are already acquainted with several species.

ICAQUE POINT, on the E. end of the island of St Domingo, lat. 19° 2′.—*Morse.*

ICE HOUSE. See that article, *Encyclopædia*. Professor Beckmann, in the third volume of his History of Inventions, has proved clearly that the ancients were well acquainted with what served the purpose of ice-houses.

"The art (says he) of preserving snow for cooling liquors during the summer, in warm countries, was known in the earliest ages. This practice is mentioned by Solomon,* and proofs of it are so numerous in the works of the Greeks and the Romans, that it is unnecessary for me to quote them, especially as they have been collected by others. How the repositories for keeping it were constructed, we are not expressly told; but it is probable that the snow was preserved in pits or trenches.

*Proverbs. xxv. 15.

"When Alexander the Great besieged the city of Petra, he caused 30 trenches to be dug, and filled with snow, which was covered with oak branches; and which kept in that manner for a long time. Plutarch says, that a covering of chaff and coarse cloth is sufficient; and at present a like method is pursued in Portugal. Where the snow has been collected in a deep gulph, some grass or green sods, covered with dung from the sheep-pens, is thrown over it; and under these it is so well preserved, that the whole summer through it is sent the distance of 60 Spanish miles to Lisbon.

"When the ancients, therefore, wished to have cooling liquors, they either drank the melted snow, or put some of it in their wine, or they placed jars filled with wine in the snow, and suffered it to cool there as long as they thought proper. That ice was also preserved for the like purpose, is probable from the testimony of various authors; but it appears not to have been used so much in warm countries as in the northern. Even at present snow is employed in Italy, Spain, and Portugal; but in Persia ice. I have never any where found an account of Grecian or Roman ice-houses. By the writers on agriculture they are not mentioned."

ICHNOGRAPHY, in architecture, is a transverse or horizontal section of a building, exhibiting the plot of the whole edifice, and of the several rooms and apartments in any story; together with the thickness of the walls and partitions; the dimensions of the doors, windows, and chimneys; the projectures of the columns and piers, with every thing visible in such a section.

ICHUA-TOWN, in the Genessee country in the State of New-York, is an Indian village at the mouth of Ichua Creek, a north-eastern head water of Alleghany river. It is 60 miles easterly of Fort Erie, 70 E. by S. of La Boeuf, and 67 S. W. by S. of Hartford on Genessee river.—*Morse.*

ICUNADA DE BARRUGAN, a town on the river La Plata, in S. America.—*ib.*

ICY CAPE is the north-westernmost head land of N. America, situated in the Northern ocean. Between this cape and Cape North, in Asia, is the opening into Behring's Straits, which lead from the Northern into the Pacific ocean.—*ib.*

JEBB (John), was born in Southampton-street, Covent Garden, London on the 16th of February, 1736. He was the eldest son of the Rev. John Jebb, dean of Cashel, in the kingdom of Ireland. He received the elements of his education in different schools, and was admitted, July 7, 1753, pensioner in the university of Dublin, whence he removed, November the 9th 1754, to St Peter's college in Cambridge, where he was likewise a pensioner. In January 1757 he proceeded to the degree of A. B. and his place in the distribution of academical honours was, on that occasion, second wrangler, the late eminent mathematician Dr Waring being the first. In 1758 he obtained the second prize of fifteen guineas, annually given by the university to the authors of the best compositions in Latin prose, being senior or middle bachelors of arts. Dr Roberts, afterwards provost of Eton college, obtained the first.

In the month of June 1760, Mr Jebb was admitted probationer fellow of St Peter's college, and proceeded to the degree of Master of Arts at the commencement in the same year; and on the first of July 1761, was confirmed fellow by Dr Mawson, bishop of Ely.

On the 6th of June 1762, he was ordained deacon at Bugden by Dr John Green, bishop of Lincoln;

Jebb. coln; and on the 25th of September, 1763, he was admitted by the fame bifhop into prieft's orders.

On the 22d of Auguft, 1764, Mr Jebb was collated by Dr Matthias Mawfon, bifhop of Ely, to the fmall vicarage of Gamlingay, near Potton, in Bedfordfhire, upon the recommendation of Dr Law, mafter of Peterhoufe. On the 17th of the following October, he was elected by the univerfity into the rectory of Ovington, near Watton, in Norfolk, after a competition with the Rev. Henry Turner, then fellow of St John's college, afterwards vicar of Burwell, in Cambridgefhire. Upon cafting up the votes, there appeared to be for Mr Jebb 91, for Mr Turner 73; and accordingly he was inftituted into the fame the 15th of December following.

On the 29th of the fame month, (December 1764) Mr Jebb married Anne, eldeft daughter of the Rev. James Torkington, rector of Little Stukeley, in Huntingdonfhire, and of lady Dorothy Sherard, daughter of Philip, fecond earl of Harborough.

Early in the year 1765, Mr Jebb, together with the Rev. Robert Thorpe, fellow of Peterhoufe, and the Rev. George Woolafton, fellow of Sidney college, publifhed, in a fmall quarto, a comment on thofe parts of Sir Ifaac Newton's *Principia* which more immediately relate to the fyftem of the world. The title of the joint work of thefe able and judicious philofophers was, "Excerpta quædam e Newtoni principiis philofophiæ naturalis, cum notis variorum." A work, of which the univerfity of Cambridge continues to bear teftimony to the excellence, by the general ufe of it in the courfe of academical education.

Mr Chappelow profeffor of Arabic, dying on the 14th of January 1768, Mr Jebb offered himfelf a candidate for the vacant chair; but it was given to Dr Hallifax, afterwards bifhop of Gloucefter; a man of deferved celebrity, of whom we regret that it was not in our power to give a biographical fketch.

On July 10. 1769, Mr Jebb was inftituted to the vicarage of Flixton, near Bungay, in Suffolk, on the prefentation of William Adair, Efq. of Flixton-hall; and on the 4th of April 1770, was inftituted to the united rectories of Homersfield and St Crofs, parifhes contiguous to Flixton, upon the fame prefentation: being alfo, in the fummer of the fame year, nominated chaplain to Robert earl of Harborough. In confequence of the acceffion of thefe preferments, though not confiderable in themfelves, he refigned, fome time in the month of October 1771, the rectory of Ovington, which he had received from the univerfity; and Mr Sheepfhanks, fellow of St John's college, was elected in his place.

Dr Hallifax fucceeding to the profefforfhip of civil law, in the month of October 1770, upon the death of Dr Ridlington, Mr Jebb once more folicited that of Arabic, which Dr Hallifax then vacated: but he had by this time difplayed fuch an innovating fpirit in religion, that the univerfity gave the vacant profefforfhip to Mr Craven, a man refpected even by Mr Jebb and his friends.

Early in the year 1771, a defign was formed of applying to parliament for relief in the matter of fubfcription to the liturgy, and thirty-nine articles of the Church of England; and in the profecution of this defign Mr Jebb took a very active part. He attended different meetings of the difcontented clergy, held at the Feathers tavern, London, affifted in the drawing up of their petition, and wrote their circular letter, which gave to the public an account of their aims. He bufied himfelf at the fame time in making various attempts to bring about what he called a reformation of the univerfity of Cambridge, but finding them fruitlefs, he retired, on the 25th of June 1772, to Bungay, where he ftudied French and Italian, and proceeded in a plan of fome *political* or *conftitutional lectures*. Jebb.

He had by this time ceafed to read the prayers of the church, though he ftill continued to preach occafionally; and the Archdeacon of Suffolk, holding, this year, his ufual vifitation of fome neighbouring parifhes in the church of Flixton, Mr Jebb preached fuch a fermon againft fubfcription, as drew upon himfelf a public rebuke from the Archdeacon, in the prefence of the clergy. "Much altercation, (fays he) enfued: and for fome days I expected a fummons to Norwich; but have heard no more of it. *I acted thus, with a view to call the attention of the Norwich clergy to our caufe;* and have in part fucceeded."

He acted much more honourably than this, when, in 1775, he refigned all his preferments in the church: which furely he ought not to have retained one day after his confcience would not permit him to read the prayers of the liturgy. He now refolved to become a phyfician; and after attending St Bartholomew's hofpital in London for fix months, as the pupil of Dr William Pitcairn, he received, on the 18th of March 1777, a diploma of Doctor of Phyfic from the univerfity of St Andrews!! He did not, however, commence practice till the 5th of February 1778; and even then he continued to attend the lectures of Dr Hunter, Mr John Hunter, and Dr Higgins. On the 18th of February 1779 he was elected a Fellow of the Royal Society.

Dr Jebb, at the breaking out of the American war, had fhewn himfelf at Cambridge a warm partizan of the revolting colonies; and of courfe a keen advocate for what he called, and, we doubt not, thought, the civil liberties of mankind. He now fignalized himfelf by "An addrefs to the Freeholders of Middlefex," affembled at Free mafon's tavern in Great Queen-ftreet, on Monday, December the 20th 1779, for the purpofe of eftablifhing meetings to maintain and fupport the freedom of election. Upon this occafion, he communicated to James Townfend, Efq. chairman of that meeting, the above addrefs, under the fignature of "Salus Publica;" prefuming, that if the fentiments "appeared to be founded in reafon, they would not be the lefs regarded on account of their being fuggefted by an unknown individual."

This addrefs was immediately printed, and very foon paffed through three editions, each being enlarged by the addition of frefh matter; and in 1782, followed the fourth edition corrected, which alfo bore our author's name in the title page.

About the end of February 1780, Dr Jebb was appointed by the committee of the county of Huntingdon, one of their deputies, to attend a meeting in London of reprefentatives from certain other petitioning counties, in order to concert meafures for the more effectual reform of the prefent conftitution of the houfe of commons. Soon afterwards he became one of the moft active members of "the fociety for conftitutional information;

Jebb.

information;" of which the object, according to their own account, was to diffuse throughout the kingdom, as universally as possible, a knowledge of the great principles of constitutional freedom, particularly such as respect the election and duration of the representative body. "With this view (say they), constitutional tracts, intended for the extension of this knowledge, and to communicate it to persons of all ranks, are printed and distributed gratis, at the expence of the society. Essays, and extracts from various authors, calculated to promote the same design, are also published under the direction of the society, in several of the newspapers; and it is the wish of the society to extend this knowledge throughout every part of the united kingdoms, and to convince men of all ranks, that it is their interest, as well as their duty, to support a free constitution, and to maintain and assert those common rights, which are essential to the dignity and to the happiness of human nature." Could Dr Jebb have foreseen all the mischiefs which have flowed from this institution; could he have foreseen the wonderful spawn of factious societies which have sprung from it as from a parent stock, our veneration for genius and learning will not permit us to believe, that he would have neglected the studies of his profession for the sake of taking the lead in party politics.

Dr Petit, one of the physicians of St Bartholomew's hospital, dying the 26th of May, Dr Jebb offered himself a candidate to succeed to that appointment. The election came on the 23d of June; when Dr Budd, his antagonist, succeeded by a great majority.

The opposition which was made to his election at St Bartholomew's, followed him in the winter, when he offered himself at St Thomas's hospital in the borough. Indeed he relinquished his pretensions there sooner than in the former place; but for no other reason than because he found that all his political principles were likely to be again objected to him, and to hazard his success.

In the year 1783 he concurred with others in forming "the society for promoting the knowledge of the scriptures," which met first on the 20th of September in that year, and whose meetings continued to be held, and, for ought we know to the contrary, are still held at Essex house. The sketch of their plan was chiefly written by Dr Jebb; and their object was to propagate the doctrines of Unitarianism, for which he was as great a zealot as for civil liberty.

His health now began to decline; but during his confinement, he studied the Saxon language, the Anglo-Saxon laws, English history and antiquities, with a view to examine into our criminal code, and particular points of liberty. The vigour of his mind was still equal to the furnishing himself with this fresh store of knowledge; he foresaw the advantage of such an acquisition in the investigation of the legal rights of Englishmen, and had designed to have employed it in the support of some great constitutional questions, which he considered as essential to the freedom of his country.

But as the year began to dawn, it was very observable to many of his friends that, according to every appearance, and without some very great and singular effort of nature, his increased debility would defeat every exertion of the most judicious medical assistance, and terminate the remaining sparks of human life.

In this enfeebled state, his mind was active. His "Thoughts on Prisons" were printed and circulated in the county of Suffolk in 1785, by his much valued friend Mr Lofft; and there is sufficient reason for concluding that this little tract had effect on the deliberations of the justices at Ipswich and Bury, then engaged in erecting a new gaol for the division of Ipswich, and a new house of correction for that of Bury.

Jeffersonia, | Jerboa.

The good effects of this very excellent tract, it was apprehended, would be extended by a more general publication. In this hope Dr Jebb revised and corrected it with his dying hand: and his surviving friend published it soon after his death, adding thereto "an abstract of felonies created by statute and other articles relative to the penal law.

He continued to linger till May the 2d 1786, when, about 8 o'clock in the evening, he breathed his last, leaving behind him, among men of different persuasions, very different characters. By the dissenters he is seldom mentioned but as the *Great Jebb;* by churchmen, his abilities are universally allowed, whilst regret is expressed that they were so often employed in support of faction and heresy. His moral character has never been aspersed.

JEFFERSONIA, a new plant lately discovered in Georgia by Dr Brickel of Savannah, and so named by him in compliment to the vice president of the United States. In the *Monthly Magazine* for July 1798 we have the following description of it:

JEFFERSONIA pentandria monogynia.

Calyx, below, composed of five short oval imbricated leaves; *corolla*, monophyllous, funnel shaped, on the receptacle, sub-pentangular, bearing the filaments near the base, its margin hypocrateriform, divided into five round ducts nearly equal; *style*, piliform, shorter than the petal, but longer than the stamens; *stigma*, quadrifid; *anthers*, erect, linear, sagittated; *fruit*, two univalved, carinated, polyspermous capsules, united at the base, opening on their tops and contiguous sides, having flat seeds, with a marginal wing.

Only one species is as yet discovered, *Jeffersonia sempervirens*. It is a shrub with round polished twining stems, which climb up on bushes and small trees; the petioles short, opposite; leaves oblong, narrow, entire, evergreen, acute; flowers axillary, yellow, having a sweet odour. The woods are full of this delightful shrub, which is covered with blossoms for many months in the year.

JERBOA, see MUS, *Encycl.* where descriptions are given of the jaculus or common jerboa, and of the Arabian, Egyptian, and Siberian jerboas. A variety of this animal has lately been found in Canada by Major-general Davies, F. R. S. and L. S. who says it belongs to Schreber's genus of Dipus, and may be thus characterised: DIPUS CANADENSIS *palmis tetradactylis, plantis pentadactylis, caudâ annulatâ undique setosâ, corpore longiore.* The truth, however, seems to be, that it is only a variety, if indeed a variety, of the Siberian jerboa. The beautiful figure indeed given by General Davies of the Canadian jerboa differs in some respects from our figure of the Sibericus. Its ears lie flat and farther down the neck; its belly is not so large; its toes are longer: and it has no brush at the end of the tail; but the habits of the two animals seem to be the same. This will

Jerboa. will be apparent from the following extracts of the General's letter to the Linnean Society:

"The first I was so fortunate to catch was taken in a large field near the falls of Montmorenci, and by its having strayed too far from the skirts of the wood, allowed myself, with the assistance of three other gentlemen, to surround it, and after an hour's hard chase to get it unhurt, though not before it was thoroughly fatigued; which might in a great measure accelerate its death.

"During the time the animal remained in its usual vigour, its agility was incredible for so small a creature. It always took progressive leaps of from three to four, and sometimes of five yards, although seldom above 12 or 14 inches from the surface of the grass; but I have frequently observed others in shrubby places and in the woods, amongst plants, where they chiefly reside, leap considerably higher. When found in such places, it is impossible to take them, from their wonderful agility, and their evading all pursuit by bounding into the thickest cover they can find."

That the Canadian, as well as the Siberian Jerboa sleeps through the winter, seems evident from a specimen having been found, towards the end of May, inclosed in a ball of clay, about the size of a cricket ball, nearly an inch in thickness, perfectly smooth within, and about twenty inches under ground. It was given to the General: who proceeds thus:

"How long it had been under ground it is impossible to say; but as I never could observe these animals in any parts of the country after the beginning of September, I conceive they lay themselves up some time in that month, or beginning of October, when the frost becomes sharp: nor did I ever see them again before the last week in May, or beginning of June. From their being enveloped in balls of clay, without any appearance of food, I conceive they sleep during the winter, and remain for that term without sustenance. As soon as I conveyed this specimen to my house, I deposited it, as it was, in a small chip box, in some cotton, waiting with great anxiety for its waking; but that not taking place at the season they generally appear, I kept it until I found it begin to smell: I then stuffed it, and preserved it in its torpid position. I am led to believe, its not recovering from that state arose from the heat of my room during the time it was in the box, a fire having been constantly burning in the stove, and which, in all probability was too great for respiration. I am led to this conception from my experience of the snow bird of that country, which always expires in a few days (after being caught, although it feeds perfectly well) if exposed to the heat of a room with a fire or stove; but being nourished with snow, and kept in a cold room or passage, will live to the middle of summer."

Another variety of this species is described by Benjamin Smith Barton, M. D. Professor of Botany and Natural History, in the University of Pennsylvania, in the fourth volume of the Transactions of the American Philosophical Society, p. 115 and 116. "This animal," says the Doctor, "is about the size of the common house-mouse. I weighed two of them. The difference in their weight was very small. That of which I have given a figure, and from which the following description is principally taken, weighed nine penny-weights, and twenty-two grains, soon after the death of the animal, and before the bowels were taken out. Like all the other species of Dipus, this is furnished with two *dentes primores*, or cutting teeth, in each jaw. These teeth are sharp at the points, and of a chesnut-brown colour. The upper-jaw projects considerably beyond the lower. The nostrils are open. The whiskers are long. The ears are small, somewhat oval, and covered. The fore-feet, or rather arms, are short, and are furnished with four toes or fingers, the nails of which are long, and very sharp. Besides these fingers, there is a kind of minute tuberculum, in place of a thumb. This tuberculum is entirely destitute of a nail. The hind legs are very long, and are furnished with five toes, the three middle ones being long, slender, and nearly of an equal length. The two side-toes are much shorter. The inner toe is the shortest of the five.

The head, the back, and the whole upper part of the body, are of a reddish-brown colour, somewhat inclining to yellow. The back is marked by a darker brown than the other parts. The whole under side of the body, beginning with the upper jaw, and ending at the anus, is of a cream colour; as are, likewise, the insides of the fore-legs, or arms, and the insides of the hind-legs.

A yellow streak, or band, beginning near the lower part of the nostrils, on each side, runs along the whole length of the head and neck, the upper and under side of the forelegs, from thence all along the body, terminating with the thighs, at the joint.

The tail is considerably longer than the body, gradually tapers from its origin, and is finely ciliated, or lightly covered with hairs, its whole length. It ends in a fine pencil of hairs. The upper side is of a slate-brown colour, the under side is of a yellowish-cream colour. It is composed of a great number of joints.

JETTE, the border made round the stilts under a pier, in certain old bridges, being the same with starling; consisting of a strong framing of timber filled with stones, chalk, &c. to preserve the foundations of the piers from injury.

IGNACIO, St, a town in the eastern part of Peru, and on the N. side of Amazon river.—*Morse.*

IGORNACHOIX, a bay in the island of Newfoundland, southward of St John's Bay.—*ib.*

Jillifree. JILLIFREE is a town on the northern bank of the river Gambia, opposite to James's island, where the English had formerly a small fort. The kingdom of Barra, in which it is situated, produces great plenty of the necessaries of life; but the chief trade of the inhabitants is in salt, which they carry up the river in canoes; and, in return, bring down Indian corn, cotton cloths, elephants teeth, small quantities of gold dust, &c. The number of canoes and people constantly employed in this trade, make the king of Barra (says Mr Park) more formidable to Europeans than any other chieftain on the river, and have encouraged him to establish those exorbitant duties, which traders of all nations are obliged to pay at entry, amounting nearly to L. 20 on every vessel, great and small. These duties, or customs, are generally collected in person by the alkaid or governor of Jillifree, who is attended by a numerous train of noisy and troublesome dependants, who, by their frequent intercourse with the English, have acquired a smattering of our language, and beg for every thing which they fancy with such earnestness, that traders, in

Ileignes, Illinois,

order to get quit of them, are frequently obliged to grant their requests. Lat. 13° 16′. Long. 16° 10′ east from Greenwich.

ILEIGNES, or *St Charles*, a town on the S. side of the island of St Domingo, and 200 fathoms from the city of St Domingo. It is inhabited by emigrants from the Canary islands, and has a few streets which run from the four cardinal points, and cut each other at right angles. The inhabitants are the most industrious people in the Spanish part of the island.—*Morse*.

ILHEOS, a captainship S. of that called Bay of All-Saints, and in the middle division of Brazil. Chief town, Paya. Ilheos, the capital of the above province, stands about 30 leagues N. E. of Porto Segaro, and as far S. W. of the Bay of All-Saints. It is watered by a river of the same name, and contains about 200 families. S. lat. 15° 40′, W. long. 34° 28′.—*ib.*

ILLINOIS, a large navigable river of the N. W. Territory, formed by the confluence of the rivers Plein, and Theakiki, in 41° 48′ N. lat. and in 88° 42′ W. longitude. This noble branch of the Mississippi, after running a serpentine S. W. course, through an extensive country of rich, fertile land, and receiving a vast number of rivers from 20 to 100 yards wide, which are navigable for boats from 15 to 180 miles, approaches within 5 miles of the Mississippi; from thence running eastward about 12 miles, it pays its tribute by a mouth 400 yards wide, in 38° 40′ N. lat. and in 92° 12′ W. longitude; opposite the large cave, 176 miles above the Ohio and 18 above the Missouri. The lands on the banks of the Illinois, particularly those on the S. E. side, are perhaps as fertile as any part of North-America. They produce in the most luxuriant plenty, wheat, rye, Indian corn, peas, beans, flax, hemp, tobacco, hops, grapes, apples, pears, peaches, dyeing roots, medicinal plants, &c. Here also grow large forests of hickory, oak, cedar, mulberry trees, &c. Savannas, or natural meadows are both numerous and extensive. In the forests are great variety of animals, as buffaloes, deer, &c. and in the rivers are plenty of fish, particularly cat, carp, and perch, of an enormous size. Such is the abundance of wild grapes in this country, that in the year 1769, the French planters upon this river made above 110 hhds. of strong wine, from these grapes. On the north-western side of this river is a coal mine, which extends for half a mile along the middle of its banks, and about the same distance below the coal mine are two salt ponds, 100 yards in circumference, and several feet in depth. The water is stagnant and of a yellowish colour; but the French and natives make good salt from it. The Illinois furnishes a communication with lake Michigan, by Chicago river, between which and the Illinois are two portages the length of which do not exceed 4 miles. The whole length of the river from the source of Theakiki, which is but a short distance from the river St Joseph, opposite to Fort St Joseph on the north, is 480 miles. The Indians have ceded to the United States, by the treaty of Greenville, in 1795, a tract of land 12 miles square, at or near the mouth of the Illinois; also a tract 6 miles square, at the Old Prarias fort and village near the south end of Illinois Lake. That lake is only a dilatation of the river, and is situated about 240 miles below the source of Theakiki, and 43 below the Salt Ponds. It is 20 miles long and 5 miles broad in the middle.—*ib.*

Illuminati.

ILLINOIS *Indians* inhabit near Cahokia on the Mississippi. Warriors 260.—*ib.*

1

Object of the Illuminati.

ILLUMINATI is the name which was assumed by a secret society or order, founded on the first of May 1776, by Dr Adam Weishaupt professor of canon law in the university of Ingolstadt. The real object of this order was, by clandestine arts, to overturn every government and every religion; to bring the sciences of civil life into contempt; and to reduce mankind to that imaginary state of Nature when they lived independent of each other on the spontaneous productions of the earth. Its avowed object, however, was very different. It professed to diffuse from secret societies, as from so many centres, the light of science over the world; to propagate the purest principles of virtue; and to re-instate mankind in the happiness which they enjoyed during the golden age fabled by the poets. Such an object was well adapted to make a deep impression on the ingenuous minds of youth; and to young men alone Weishaupt at first addressed himself.

It will naturally occur to the reader, that the means of attaining this glorious object should have been made as public as possible; and that the veil of secrecy thrown over the proceedings of the order was calculated to excite suspicion, and to keep even *young* men of virtue and sagacity at a distance. In any other country than Germany secrecy might perhaps have had this effect; but various circumstances conspired there to make it operate with a powerful attraction.

Ever since free-masonry had acquired such reputation throughout Europe, a multitude of petty secret societies had been formed in the universities of Germany, each having its lodge, its master, its mysteries, all modelled on those founded by masons coming from England and Scotland (A). Before the foundation of Weishaupt's order, these lodges, we believe, were in general harmless; or if they were productive of any evil, it was only by giving the youth of the universities a taste for secrecy and mysticism. Of this Weishaupt availed himself; and as soon as he had conceived the outlines of his plan, and digested part of his system, he initiated two of his own pupils, to whom he gave the names of

(A) Such, we are sorry to say, is the case still. In a letter, dated the 10th of May 1799, which we received from a gentleman of learning and honour then residing in Upper Saxony, is the following account of the university of Jena: "This university contains from two to three thousand students, who are almost all republicans, and go about the country in republican uniforms. They are all formed into clubs or *secret societies;* and the quarrel of one member of a club is taken up by all. The consequence is, that the number of duels among the different clubs is inconceiveable. The weapon is generally the sabre, and the duel often ends in the death of one of the combatants." Yet gentlemen of Great Britain send their sons to Germany to be educated!

of Ajax and Tiberius, assuming that of Spartacus to himself. These two disciples soon vying with their master in impiety (for it will be seen by and bye that he was most impious), he judged them worthy of being admitted to his mysteries, and conferred on them the highest degree which he had as yet invented. He called them *Areopagites*, denominated this monstrous association, THE ORDER OF ILLUMINATI, OR ILLUMINEES, and installed himself GENERAL of the order.

When public report spread the news in Germany of this new order having been founded in the university of Ingolstadt by Weishaupt, it was generally supposed to be one of those little college-lodges which could not interest the adepts after they had finished their studies. Many even thought that Weishaupt, who was at that time a sworn enemy to the Jesuits, had founded this lodge with no other view than to form a party for himself against these fathers, who after the suppression of their order, had been continued in their offices of public teachers at the university of Ingolstadt; and this opinion the illuminees were at pains to propagate. His character, too, was at this time such as to remove every suspicion from the public mind. A seeming assiduity in his duty, and a great shew of zeal and erudition in expounding the laws, easily misled people to believe that his whole time and talents were engrossed with the study of them; and if we are to credit his own account, Ingolstadt had never witnessed a professor so well calculated to add new lustre to its university.

2
Art of the founder.

This seems, indeed, to have been the general opinion as well as his own; for, some time after the foundation of his order, he applied himself with such diligence and apparent candour to the duties of his office, that he was chosen what Abbé Barruel's translator calls SUPERIOR of the university. This new dignity only added to his hypocrisy, and furnished him with fresh means of carrying on his dark designs. He converted his house into one of those boarding-houses where young men, perpetually under the eye of their masters, are supposed to be better preserved than anywhere else from the dangers which threaten them at that age. He solicited fathers and mothers to entrust their children to his care; and, counterbalancing in secret the lessons which he was obliged to give in public, he sent home his pupils well disposed to continue the same career of seduction which he himself carried on at Ingolstadt. Atrociously impious, we see him (says M. Barruel), in the first year of his illuminism, aping the God of Christianity, and ordering *Ajax*, in the following terms, to propagate the doctrines of his new gospel: "Did not Christ send his apostles to preach his gospel to the universe? You that are my Peter, why should you remain idle at home? Go then and preach."

These preachers had yet received no particular designation; for when his first adepts were initiated, he was far from having completed the code of his order. He knew that years and experience were necessary to perfect that gradual system of initiations and trials which, according to the plan he had conceived, his novices were to undergo; but he could not endure the idea of sacrificing years to mere theoretic projects; and he flattered himself with the hopes of supplying the deficiencies of his incomplete code by provisional regulations and private instructions, and of acquiring associates who would receive his new gospel implicitly, and co-operate with him in all his views.

3
The sect divided into classes of

At length, however, the code was completed, and the sect divided into two grand classes; and each of these again subdivided into lesser degrees, proportioned to the progress of the adepts.

4
Preparation and

"The *first* class is that of Preparation. It contains four degrees, viz. those of *Novice*, of *Minerval*, of *Minor Illuminee*, or *Illuminatus Minor*, and of *Major Illuminee*, or *Illuminatus Major*. To this class belong likewise some intermediary degrees, borrowed from free-masonry, as means of propagation. Of the masonic degrees, the code of the illuminati admits the first three without *any alteration*; but it adapts more particularly to the views of the sect the degree of *Scotch Knight*, and styles it the degree of *Directing Illuminee*, or *Illuminatus dirigens*.

5
The Mysteries.

The *second* class is that of the Mysteries, which are subdivided into the *lesser* and *greater mysteries*. The lesser comprehend the priesthood, and administration of the sect, or the degrees of *priests*, and of *regents* or *princes*.

In the *greater mysteries* are comprehended the two degrees of *Magus*, or philosopher, and of the *Man-king*. The *elect* of the latter compose *the council and degree of Areopagites*.

6
The recruiter.

"In all these classes, and in every degree (says the Abbé Barruel), there is an office of the utmost consequence, and which is common to all the brethren. It is that which is occupied by him who is known in the code by the appellation of *Recruiter*, or *Brother Insinuator*. This (continues our author) is not a term of my invention: it is really to be found in the code, and is the denomination of that illuminee whose employment is to entice members into the sect."

As the whole strength of the order depended upon the vigilant and successful exercise of this office, some brethren were carefully instructed for it who might afterwards visit the different towns, provinces and kingdoms, in order to propagate the doctrines of illuminism. Weishaupt proposed to select as his apostles either weak men who would implicitly obey his orders, or men of abilities, who would improve the office by artifices of their own. It was, however, a duty which every brother was obliged to exercise once or twice in his life, under the penalty of being for ever condemned to the lower degrees.

To stimulate the ardour of the brother insinuator, he was appointed superior over every novice whom he should convert. To assist his judgment, he was instructed in three important points concerning the description of men whom he ought to select for conversion, the means which he ought to employ for enticing them to enter the order, and the arts which he ought to study to form their character.

7
To pry into the characters of all men.

To enable the recruiter to determine whom he ought to select for conversion, he was to insinuate himself into all companies; he was to pry into the character of all whom he should meet with, whether friends, relations, strangers or enemies; he was to write down all his remarks regularly every day; to point out their strong and weak sides, their passions and prejudices, their intimacies, their interests, and their fortune. This journal was to be transmitted twice every month to the superiors; by which means the order would learn who were friendly or hoſtile to their views, and who were the individuals to whom they ought to direct their arts of ſeduction (B).

The perſons to be excluded were all ſuch as would expoſe the order to ſuſpicion or reproach. All indiſcreet talkers, all who were proved violent, and difficult to be managed, all addicted to drunkenneſs, and all Pagans, Jews, and Jeſuits, were to be rejected. As the patronage of princes would tend much to enrich and ſtrengthen the ſociety, it was agreed to admit them to the interior degrees, but they were never to be initiated into the grand myſteries; they were never to riſe beyond the degree of Scotch knight.

8 Perſons proper for the order,

The perſons to be ſelected were young men of all ſtations, from eighteen to thirty; but particularly thoſe whoſe education was not completed, and conſequently whoſe habits were not formed. "Seek me out (ſays Weiſhaupt in his directions to the inſinuator) the dexterous and daſhing youths. We muſt have adepts who are inſinuating, intriguing, full of reſource, bold and enterpriſing; they muſt alſo be flexible and tractable, obedient, docile, and ſociable." In another place he ſays, "Above all things pay attention to the figure, and ſelect the well made men and handſome young fellows. They are generally of engaging manners and nice feelings. When properly formed, they are the beſt adapted for negociations; for firſt appearances prepoſſeſs in their favour. It is true, they have not the depth that men of more gloomy countenances often have. *They are not the perſons to be entruſted with a revolt, or the care of ſtirring up the people;* but it is for that very reaſon we muſt know how to chooſe our agents. I am particularly fond of thoſe men whoſe very ſoul is painted in their eyes, whoſe foreheads are high, and whoſe countenances are open. Above all, examine well the eyes, for they are the very mirrors of the heart and ſoul. Obſerve the look, the gait, the voice. Every external appearance leads us to diſtinguiſh thoſe who are fit for our ſchool."

Though young men were preferred, yet perſons of all ages were to be admitted if their character accorded with the principles of the order. The inſinuator was deſired to ſeek out thoſe who were diſtinguiſhed by their power, riches, or learning. "Spare no pains (ſays Weiſhaupt), ſpare nothing in the acquiſition of ſuch adepts. If heaven refuſe its ſuccour, conjure hell.

9 To be ſeduced by whatever means;

Flectere ſi nequeas ſuperos, Acheronta moveto."

Perſons were to be ſingled out from thoſe profeſſions which give men influence over others, or put them in the moſt favourable ſituation for diſſeminating any peculiar opinions. With this view, ſchoolmaſters, and ſuperintendants of eccleſiaſtic ſeminaries, were to be ſought after with much care. Bookſellers, poſt-maſters, and the ſecretaries of poſt offices were alſo to be ſelected. Thoſe profeſſions which accuſtomed men to ſpeak and argue, as that of counſellors and attorneys, and even phyſicians, were alſo to be courted. "They are worth having (ſays Weiſhaupt), but they are ſometimes real devils, ſo difficult are they to be led; they are, however, worth having when they can be gained over." Every exertion was to be made to gain the officers of a prince, whether preſiding over provinces or attending him in his councils. "He that has done this, has done more than if he had engaged the prince himſelf."

There was alſo another deſcription of men of whom Weiſhaupt very wiſely judged that they would be admirably fitted for the diffuſion of his doctines. Theſe were the diſappointed and diſſatisfied. "Select thoſe in particular (ſays he) who have met with misfortunes, not from accidents, but from ſome injuſtice; that is to ſay, in other words, the diſcontented; for ſuch men are to be called into the boſom of illuminiſm as into their proper aſylum.

10 And their characters tranſmitted to the ſuperiors.

When the inſinuator has made choice of his victim, he is required to draw from his diary a view of his character, opinions, principles, and connections. This he is to tranſmit to the ſuperiors for their examination, and that they may compare it with the diaries which they have already received, perhaps from different inſinuators. When the choice of the inſinuator is approved, the ſuperiors determine which of the inſinuators will be beſt qualified to perform the taſk of ſeducing their candidate.

Two different methods were recommended; one of which

(B) As a ſpecimen of the journals kept by the inſinuators, and of the characters which the illuminees ſelected for propagating their principles, we ſhall give the character of Zwack, denominated *Cato*, as it is deſcribed in the tablet of his inſinuator Ajax (Maſſenhauſen).

"Francis Xaverius Zwack was ſon of Philip Zwack, commiſſary of the *Chambre des Comptes*, and was born at Ratiſbon; at the time of his initiation (29th May 1776) he was twenty years of age, and had finiſhed his college education.

"He was then about five feet high; his perſon emaciated with debauchery; his conſtitution bordering on melancholy; his eyes of a dirty grey, weak and languiſhing; his complexion pale and ſallow; his health weak, and much hurt by frequent diſorders; his noſe long, crooked and hooked; his hair light brown; gait precipitate; his eyes always caſt towards the ground; under the noſe and on each ſide of the mouth, a mole.

"His heart tender and philanthropic in an extraordinary degree; but ſtoic when in a melancholy mood; otherwiſe a true friend, circumſpect, reſerved, extremely ſecret; often ſpeaking advantageouſly of himſelf; envious of other people's perfections; voluptuous; endeavouring to improve himſelf; little calculated for numerous aſſemblies; choleric and violent, but eaſily appeaſed; willingly giving his private opinions when one has the precaution to praiſe him, though contradicting him; a lover of novelties. On religion and conſcience widely differing from the received ideas; and thinking preciſely as he ought, to become a good member of the order.

"His predominant paſſions are, pride, love of glory, probity; he is eaſily provoked; has an extraordinary propenſity for myſteries; a perpetual cuſtom of ſpeaking of himſelf and of his own perfections; he is alſo a perfect maſter in the arts of diſſimulation; a proper perſon to be received into the order, as applying himſelf particularly to the ſtudy of the human heart." Such is the character of the beloved diſciple of Weiſhaupt, the incomparable Cato, and a leader of the ſect of the illuminees!

which was to be employed in enticing men who were ſomewhat advanced in life or diſtinguiſhed by ſcience; the other was to be uſed in ſeducing young men whoſe character was not formed.

11 Proper methods of ſeducing men of knowledge,

With men of knowledge, who had already imbibed the principles of modern philoſophiſm (for no true philoſophers were to be attempted), the inſinuator was to aſſume the character of a philoſopher well acquainted with the myſteries of ancient times. He was to deſcant upon the importance of the ſecret doctrines tranſmitted by tradition, to quote the gymnoſophiſts of India, the prieſts of Iſis in Egypt, and thoſe of Eleuſis, with the Pythagorean ſchool in Greece. He was to learn by heart certain paſſages from Iſocrates, Cicero, and Seneca, that he might have them ready upon all occaſions. He was to throw out hints, that theſe ſecret doctrines explained the difficult queſtions concerning the origin and order of the univerſe, the Providence of God, the nature of the ſoul, its immortality and future deſtination; he was to inſpire them with the belief that the knowledge of theſe things would render life more agreeable and pain more ſupportable, and would enlarge their ideas of the majeſty of God: he was then to declare that he had been initiated into theſe myſteries. If the candidate expreſſed any curioſity to be made acquainted with them, the inſinuator was firſt to aſcertain his opinions upon ſome leading points, by propoſing to him to write a diſſertation upon certain queſtions. Should the anſwers not pleaſe the inſinuator, he was to relinquiſh his prey; but ſhould they be ſatisfactory, the candidate was to be admitted to the firſt degree.

12 And young men,

When the ſelected victim was young, and had not imbibed any of thoſe opinions which correſponded with the principles of the ſect, a different method was to be followed. "Let your firſt care (ſays the legiſlator to his inſinuators) be to gain the affection, the confidence, and the eſteem of thoſe whom you are to entice into the order. Let your whole conduct be ſuch, that they ſhall ſurmiſe ſomething more in you than you wiſh to ſhew; hint, that you belong to ſome ſecret and powerful ſociety; excite by degrees, and not at once, a wiſh in your candidate to belong to a ſimilar ſociety. Certain arguments and certain books, which the inſinuator muſt have, will greatly contribute to raiſe ſuch a wiſh; ſuch, for example, are thoſe which treat of the union and ſtrength of aſſociations."

Every inſinuator muſt be provided with books of this ſort. But that their ſucceſs might not depend ſolely upon books, Weiſhaupt gave to his diſciples a ſpecimen of the artifices which they might employ. The inſinuator might begin by obſerving, that a child in the cradle, abandoned to itſelf, is entirely helpleſs; and that it is by the aſſiſtance of others that it acquires ſtrength; and that princes owe their greatneſs and their power to the union of their ſubjects. Then the inſinuator might touch on the importance of knowing mankind, and the arts of governing them; that one man of parts might eaſily lead hundreds, even thouſands, if he but knew his advantages. He was next to dwell upon the defects of civil ſociety; to mention how little relief a man can obtain even from his beſt friends; and how very neceſſary it is for individuals to ſupport one another in theſe days: to add, that men would triumph even over heaven were they but united. He was to adduce as examples, the influence of the freemaſons and of the Jeſuits. He was to aſſert, that all the great events which take place in the world depend upon hidden cauſes, which theſe ſocieties powerfully influence. He was to awake in the breaſt of his pupil the deſire of reigning in ſecret; of preparing in his cloſet a new conſtitution for the world; and of governing thoſe who think they govern others.

After theſe, or other artifices of the ſame kind, have been employed, if the candidate be inſpired with an ardour to be initiated, and give ſatisfactory anſwers to the queſtions propoſed to him, he is immediately admitted a novice. But ſhould he reject all means of ſeduction, let him take heed to himſelf; "for the vengeance of ſecret ſocieties is not a common vengeance; it is the hidden fire of wrath. It is irreconcileable; and ſcarcely ever does it ceaſe the purſuit of its victims until it has ſeen them immolated." 13 Into the noviciate.

The period of the noviciate varied according to the age of the new convert to illuminiſm. At firſt it continued three years for thoſe under eighteen years of age, two years for thoſe between eighteen and twenty-four, and one year for thoſe who were near thirty; but it was afterwards ſhortened. 14 Period of the noviciate.

The novice was not acquainted with any of the order except his inſinuator, under whoſe direction he remained during his noviciate. The firſt leſſons which he was taught reſpected the inviolable nature of the ſecrecy which every illuminee was obliged to obſerve. He was told that ſilence and ſecrecy were the very ſoul of the order; that ingenuouſneſs was a virtue only with reſpect to his ſuperiors; and that diſtruſt and reſerve were fundamental principles. He was enjoined never to ſpeak of any circumſtance relating to the order, concerning his own admiſſion, or the degree which he had received, not even before brethren, without the ſtrongeſt neceſſity; and was required to ſign a declaration to this purpoſe.

The novice was next taught the dictionary of the order, its geography, calendar, and cypher. To prevent the poſſibility of diſcovery, every illuminee received a new name, which was characteriſtic of his diſpoſitions, or of the ſervices which were expected of him. Thus Weiſhaupt, as we have obſerved, was called *Spartacus*, becauſe he pretended to wage war againſt thoſe oppreſſors who had reduced mankind to ſlavery; and Zwack, as we have ſeen, was named *Cato*, becauſe he had written a diſſertation in favour of ſuicide, and had once determined to commit that crime. 15 Dictionary, geography, calendar, and cypher of the order.

According to the new geography of the order, Bavaria was called *Achaia*; Munich was called *Athens*; Vienna was named *Rome*; Wurtzburgh was denominated *Carthage*; and Ingolſtadt, the fountain of the order, was called *Epheſus*, and by the profound adepts *Eleuſis*. The novice had alſo to learn the Perſian calendar, which the order had adopted. Their era began A. D. 630. The months received new names: May was called *Adarpahaſcht*; June, *Chardad*; July, *Thermeh*; Auguſt *Merdedmeh*; and ſo on. The cypher conſiſted of numbers which correſponded to the letters of the alphabet, in this order *a*, *b*, *c*, *d*, anſwering to the numbers 12, 11, 10, 9.

The novice had next to ſtudy *the ſtatutes of the illuminees*, which he was aſſured contained nothing injurious to the ſtate, to religion, or to good morals. He was next deſired to apply himſelf to acquire the morality of the order: which he was to do, not by reading the goſpels,

Illuminati.

ſpels, but by peruſing Epictetus, Seneca, and Antoninus, and by ſtudying the works of the modern ſophiſts Weiland, Meiners, and Helvetius, &c. The ſtudy of man was alſo recommended as the moſt intereſting of all the ſciences. He was taught this ſtudy not merely as a ſcience, but as an art. A model of a journal was given him, and he was required to inſert in it obſervations upon the character of every perſon that he happened to meet with. To quicken his diligence, the inſinuator occaſionally examined his journal. In the mean time the inſinuator was watching him as a centinel, and noting down regularly obſervations upon the defects and merits of his pupil, which he always ſent to his ſuperiors.

16 Novice obliged to draw his own character.

The great object of the inſinuator was to entangle the novice, and to bind him indiſſolubly to the order. With this view he required the novice to draw a faithful picture of himſelf, under the pretence that he would thus know himſelf better. He deſired him to write down his name, his age, his country, his reſidence, and his employment; to give a liſt of the books in his library; to ſtate his revenue; to enumerate his friends and enemies, and the cauſe of his enmities. He was alſo to give a ſimilar account of his father and mother, his brothers and ſiſters, and to be very careful in pointing out their paſſions and prejudices, their ſtrong and weak ſides.

In the mean time, the inſinuator was occupied in drawing up a new ſtatement of every thing he had been able to diſcover of the character and conduct of the novice. This ſtatement was tranſmitted to the ſuperiors, and compared with the former. If the novice was approved, he was then admitted to the ſecond degree, upon his anſwering, in a ſatisfactory manner, twenty-four grand queſtions, which might enable the order to judge of his principles and the credit to which he was entitled, and would fix him down by ſtronger ties to the authority of the ſuperiors. The deteſtable principles of the illuminees now begin to appear, as will be evident from the following queſtions which we have ſelected:

17 Power of life and death claimed by the ſociety.

Have you ſeriouſly reflected on the importance of the ſtep you take, in binding yourſelf by engagements that are unknown to you? Should you ever diſcover in the order any thing wicked or unjuſt to be done, what part would you take? Do you, moreover, grant the power of life and death to our order or ſociety? Are you diſpoſed, upon all occaſions, to give the preference to men of our order over all other men? Do you ſubject yourſelf *to a blind obedience, without any reſtriction whatſoever?*

The novice having thus ſurrendered his conſcience, his will, and his life, to the devotion of the conſpirators, and thus ſubſcribed, with his own hand, and confirmed by his oath, a reſolution to become the moſt abject ſlave, was now deemed qualified to aſcend to the ſecond degree, called *Minerval*.

18 Admiſſion to the degree of Minerval.

In the dead hour of midnight he was conducted to a retired apartment, where two of the order were waiting to receive him. The ſuperior, or his delegate, appeared ſtanding in a ſevere and threatening poſture; he held a glimmering lamp in his hand, and a naked ſword lay before him. The novice was aſked, whether he ſtill perſiſted in his intention of adhering to the order? Upon anſwering in the affirmative, he was ordered into a dark room, there to meditate in ſilence on his reſolution. On his return, he was ſtrictly and repeatedly queſtioned if he was determined to give implicit obedience to all the laws of the order? The inſinuator became ſecurity for his pupil, and then requeſted for him the protection of the order, which the ſuperior granted with great ſolemnity, proteſting that nothing would be found there hurtful to religion, to morals, or to the ſtate. Having thus ſaid, the ſuperior takes up the naked ſword, and pointing it at the heart of the novice, threatens him with the fatal conſequences of betraying the ſecrets of the order. The novice again takes an oath, by which he binds himſelf, in the moſt unlimited manner, to ſerve the order with his life, honour, and eſtate, and to obſerve an inviolable obedience and fidelity to all his ſuperiors. He is then admitted a Minerval, and henceforth is allowed to attend the academy of the ſect.

Illuminati.

The Minerval academy was compoſed of 10, 12, or 15 Minervals, and placed under the direction of a major Illuminee. It met twice every month in an inner apartment, ſeparated from the other rooms of the manſion by an antichamber; the door of which was to be ſhut with care during the meeting, and ſtrongly ſecured by bolts. At the commencement of every meeting, the preſident read and commented upon ſome ſelect paſſages of the Bible, Seneca, Epictetus, Marcus Aurelius, or Confucius; evidently with a view of diminiſhing the reverence for the ſacred writings, by thus placing them on a level with the heathen moraliſts. Then each brother was aſked what books he had read ſince laſt meeting, what obſervations he had made, and what ſervices he had performed for promoting the ſucceſs of the order? 19 Minerval academy;

To each Minerval academy a library belonged. This was formed by the contributions of the brethren, by preſents of books, and by another method very extraordinary. All Illuminees acting as librarians, or keepers of archives, were admoniſhed to *ſteal* ſuch books or manuſcripts as might be uſeful to the order. At one time, ſending a liſt of the books which he wiſhed to be embezzled from the library of the Carmes, Weiſhaupt ſays, "All theſe would be of much greater uſe if they were in our hands. What do thoſe raſcals do with all theſe books?" 20 Its library.

Every brother at his admiſſion was required to declare to what art or ſcience he meant chiefly to apply; and it was expected, that he ſhould afterwards every year give an account of the diſcoveries or improvements which he had made. All the other brethren who were occupied in the ſame ſtudies, were deſired to give him every poſſible aſſiſtance. Thus a kind of academy was formed, to which thoſe who could not ſerve it by their talents might give pecuniary contributions. That this academy might have the appearance of a literary ſociety, prizes were annually diſtributed; the beſt diſcourſe was publiſhed, and the profits ſent to the coffers of the order.

Every month the preſident was to take a review of the faults which he had obſerved in his pupils, and examine them concerning thoſe which they might have been conſcious of in themſelves; and it would be an unpardonable neglect, ſay the ſtatutes, ſhould any pupil pretend, that during the ſpace of a whole month he had remarked nothing reprehenſible.

It is impoſſible to read theſe rules without admiring them. Were men but half as anxious, attentive, and careful, to render themſelves good citizens and good men

Illuminati. men, as these men were to render themselves successful conspirators, what a blessed world should we see!

21 Admission to the degree of minor illuminee. The Minerval was rigorously scrutinized, whether he was ready to submit to every torture, or even to commit suicide, rather than give any information against the order. Suicide was reckoned not only innocent, but honourable, and was also represented as a peculiar species of voluptuousness. In order to discover the sentiments of the Minervals upon this subject, they were required to write a dissertation upon the character and death of Cato, or any similar subject. They were also desired to discuss the favourite doctrine of Weishaupt, that *the end sanctifies the means*; a principle of the most pernicious tendency, which would render calumny, assassination, sedition, and treason, laudable, and excellent. Next, they were called upon to compose a dissertation, by which their opinions concerning kings and priests might be ascertained. If they performed all these tasks with the spirit of an infidel, and the desperate firmness of a conspirator, they were then judged worthy of being promoted to the degree of minor illuminee.

22 Minor illuminees trained for the degree of The minor illuminees held meetings similar to those of the Minerval academy. It was necessary that the president should be one who was raised to the degree of priest, and initiated in the mysteries: but he was required to persuade his pupils, that beyond the degree which he had attained there were no mysteries to be disclosed. The minor illuminees were to be so trained, that they might look upon themselves as the founders of the order; that by this powerful motive they might be animated to diligence and exertion. With this view, hints were scattered rather than precepts enjoined. It was insinuated, that the world was not so delightful as it ought; that the happiness for which man was made is prevented by the misfortunes of some, and the crimes of others; that the wicked have power over the good; that partial insurrection is useless; and that peace, contentment, and safety, might be easily obtained by means drawn from the greatest degree of force of which human nature is capable. Such views, it is added, actuating a secret society, would not only be innocent, but most worthy of the wise and well-disposed.

Weishaupt had formed, with peculiar care, a code for this degree, which was intitled *Instructions for forming useful Labourers in Illuminism*. These instructions discover an astonishing knowledge of human nature, and are drawn up with a degree of systematic coolness which perhaps no conspirator before him ever exhibited. He lays down rules, by which the character of almost any person may be ascertained. He recommends to the minor illuminees, to attend to the conduct of any person entrusted to their care, at two periods; when he is tempted to be what he ought not to be, and when, removed from the influence of every external temptation, he follows the dictates of his inclination. They were to study the peculiar habits and ruling passions of each; to kindle his ardour by descanting on the dignity of the order, and the utility of its labours; to infuse a spirit of observation, by asking questions, and applauding the wisdom of the answers; to correct the failings of their pupil, by speaking of them as if they were not his, and thus making him judge in his own cause; to instruct and advise, not by tedious declamation, but by sometimes dropping a few words to the purpose, when the mind should be in a proper state to receive them. Above all, they were directed to avail themselves of those moments when they observed a pupil discontented with the world. "It is then (says Weishaupt) you must press the swelling heart, stimulate the sensibility, and demonstrate how necessary secret societies are for the attainment of a better order of things." Illuminati.

Having passed with applause through the states of probation already described, the minor illuminee is promoted to the rank of major illuminee, or Scotch novice. As major illuminee, he is encompassed with more rigid chains; and as Scotch novice, he is dispatched as a missionary into masonic lodges, to convert the brethren to illuminism. 23 Scotch novice.

The candidate for this degree is strictly examined, in order to discover what opinions he now entertains concerning the object of the society; the motives that prompted him to join it; whether he is disposed still to co-operate with the rest of the brethren in accomplishing the grand object; and whether he be a member of any other society; and what are the duties which it requires.

The fertile genius of Weishaupt is not exhausted; he has still in reserve artifices more profound, and bonds more powerful; his resources keep pace with the progress of his schemes. He now lays a snare for his pupils, from which he hopes none can escape, and therefore he flatters himself they are his for ever. He demands of every candidate for higher degrees, to write, as a proof of confidence, a minute and faithful account of his whole life, without any reserve or dissimulation. Reserve or dissimulation would indeed be vain; for the most secret circumstances of his life are already well known to the adepts, my means of innumerable spies, who, by the appointment of the superiors, have, unknown to him, been watching and scrutinizing all his actions and words, his temper, passions, and opinions. 24 Candidates for higher degrees submit to new trials.

Now is presented to the candidate the code of the brother scrutator, called by the order the *nosce te ipsum* (know thyself). This is a catechism, containing from a thousand to fifteen hundred questions, concerning his person, his health, his education, his opinions, his inclinations, his habits, his passions, his prejudices, and even his weaknesses. Questions are also proposed respecting his acquaintances, his relations, friends, and enemies. The candidate is required to enumerate his favourite colours, to describe his language, the nature of his conversation, his gait and gestures. Nothing, in short, is omitted that can tend to distinguish his character as an individual, or as a member of society. Upon many qualities in his character, thirty, forty, or sometimes near a hundred questions are proposed. The following specimen will enable the reader to judge what astonishing care Weishaupt employed to discriminate characters.

Is his *gait* slow, quick, or firm? Are his steps long, short, dragging, lazy, or skipping? Is his *language* regular, disorderly, or interrupted? In speaking, does he agitate his hands, his head, or his body with vivacity? Does he close upon the person he is speaking to? Does he hold him by the arm, clothes, or button hole? Is he a great talker, or is he taciturn? If so, why? Is it through prudence, ignorance, respect, or sloth? &c. Concerning his *education*, he is questioned to whom does he owe it? Has he always been under the eyes of his parents? How has he been brought up? Has he

any

any esteem for his masters? Has he travelled, and in what countries?

By these questions his temper and dispositions might be accurately known. His leading passions would be discovered by the following queries. "When he finds himself with different parties, which does he adopt; the strongest or the weakest; the wittiest or the most stupid? Or does he form a third? Is he constant and firm in spite of all obstacles? How is he to be gained? by praise, by flattery, or low courtship; by women, money, or the entreaties of his friends? Does he love satire; and on what does he exercise that talent? on religion, hypocrisy, intolerance, government, ministers, monks?" &c.

All these questions are to be answered and illustrated by facts. It is necessary to observe, that the scrutators also give in written answers to all these questions. When the candidate has thus given a minute history of his life, and revealed all his secrets, his foibles, his errors, his vices, and his crimes, Weishaupt triumphantly exclaims, "Now I hold him; I defy him to hurt us; if he should wish to betray us, we have also his secrets."

The adept is next introduced into a dark apartment, where he solemnly swears to keep secret whatever he may learn from the order. He then delivers up the history of his life, sealed, when it is read to the lodge, and compared with the character drawn of him by the brother scrutators. A corner of the veil is now lifted up, still, however, with extreme caution. Nothing appears palpable but the purest principles and most generous designs. At the same time many things are darkly suggested, which are incompatible with purity and generosity; for while the utmost care is employed to deceive the understanding, nothing is neglected that can tend secretly to corrupt the heart. A number of questions are asked; the evident intention of which is to make the adept discontented with the present moral government of the world, and to excite the desire of attempting a great revolution. After answering these questions, the secretary opens the code of the lodge; and having informed the young illuminee that the object of the order is to diffuse the pure truth, and to make virtue triumph, he proceeds to show that this is to be accomplished by freeing men from their prejudices, and enlightening their understandings. "To attain this, (continues the secretary), we must trace the origin of all sciences, we must reward oppressed talents, we must undertake the education of youth; and, forming an indissoluble league among the most powerful geniuses, we must boldly, though with prudence, combat superstition, incredulity, and folly; and at length form our people to true, just, and uniform principles on all subjects." The secretary adds, that in attempting to divest vice of its power, that the virtuous may be rewarded even in this world, the order is counteracted by *princes and priests, and the political constitutions of nations*; that, however, it was not intended to excite revolutions and oppose force by force, but merely to bind the hands of the protectors of disorder, and to govern without appearing to command; that the powers of the earth must be encompassed with a legion of indefatigable men, all directing their labours towards the improvement of human nature. Were there but a certain number of such men in every country, each might form two others. "Let these (says he) only be united, and nothing will be impossible to our order." All this is very specious: it is well contrived to fascinate the imagination of the young, and the heart of the generous and benevolent, while, under all this pretended regard to virtue and to the happiness of mankind, is concealed a most formidable conspiracy against the peace of the world.

After this address is delivered, the major illuminee is presented with the codes of the insinuator and scrutator; for he must now inspect the pupils of the insinuators, and must exercise the office of scrutator while presiding over the Minerval academies.

25 The degree of Scotch knight.

The next degree, which is that of Scotch knight, is both intermediate and stationary. It is stationary for those who are not sufficiently imbued with the principles of the order, and intermediate for those who have imbibed the true spirit of illuminism. The Scotch knights were appointed the directors of all the preparatory degrees, and to watch over the interests of the order within their district. They were to study plans for increasing the revenues of the order, and to endeavour to promote to public offices of confidence, of power and wealth, as many of the adepts as possible; and to strive to acquire an absolute sway in the masonic lodges. They were to procure the management of the masonic funds; and while they were to persuade the brethren that these were expended according to their own orders, they were to employ them for promoting the views of the order. Thus one office of the Scotch knights was to embezzle the money that was entrusted to them, in order to diffuse truth, and to make virtue triumph.

After passing with applause through this long and tedious probation, the adept is introduced to the class of the mysteries. He is not yet, however, made acquainted with the whole secrets of the society; he must still submit to new trials; his curiosity must be farther excited, his imagination must be kept longer upon the stretch, and his principles of depravity be rendered more violent and inveterate before the vail be entirely withdrawn, which will discover to him Weishaupt and his infernal crew, plotting the destruction of the laws, sciences and religion of mankind. The degree of epopt or priest, to which the adept was next raised, opened to view, however, so great a part of the mysteries, that the reader will be fully prepared to expect the secrets which remain to be unfolded in the other degrees.

26 Preparations for the priesthood.

Before being admitted to the degree of epopt, the adept was required to give a written answer to ten preliminary questions. The insinuations against the established order of the world, which had formerly been slightly mentioned, increase now to an indirect proposal to attempt a complete revolution. The candidate is asked, whether he thinks the world has arrived at that happy state which was intended by nature? Whether civil associations and religion attain the ends for which they were designed? Whether the sciences are conducive to real happiness? or whether they are not merely the offspring of the unnatural state in which men live, and the crude inventions of crazy brains? It is then proposed as a question, whether there did not in ancient times exist an order of things more simple and happy? What are the best means for restoring mankind, Illuminati. kind to that state of felicity? Should it be by public measures, by violent revolutions, *or by any means that would ensure success?* Would it not be proper, with this view, to preach to mankind a religion more perfect, and a philosophy more elevated? And, in the meantime, is it not advisable to disseminate the truth in secret societies?

Should the answers given to these questions accord with the sentiments of the order, on the day fixed for the initiation, the candidate is blindfolded, and, along with his introducer, is put into a carriage, the windows of which are darkened. After many windings and turnings, which it would be impossible for the adept to trace back, he is conducted to the porch of the temple of the mysteries. His guide strips him of the masonic insignia which he wore as a knight, removes the bandage from his eyes, and presents him with a drawn sword; and then having strictly enjoined him not to advance a step till he is called, leaves him to his meditations. At length he hears a voice exclaiming, "Come, enter, unhappy fugitive; the fathers wait for you; enter, and shut the door after you." He advances into the temple, where he sees a throne with a rich canopy rising above it, and before it, lying upon a table, a crown, a sceptre, a sword, some pieces of gold, and precious jewels, interlaid with chains. At the foot of the table, on a scarlet cushion, lie a white robe, a girdle, and the simple ornaments of the sacerdotal order. The candidate is required to make his choice of the attributes of royalty, or of the white robe. If he chuse the white robe, which he knows it is expected he should do, the hierophant, or instructor, thus addresses him: "Health and happiness to your great and noble soul. Such was the choice we expected from you. But stop; it is not permitted you to invest yourself with that robe until you have heard to what we now destine you." The candidate is then ordered to sit down; the book of the mysteries is opened, and the whole brethren listen in silence to the voice of the hierophant.

27 Instructions previous to admission. The exordium is long and pompous; much artifice is concealed in it, and much eloquence displayed. It expatiates on the sublime and generous views of the society; evidently with the desire of lulling asleep the suspicion of the candidate, of exciting him to admiration, and of inspiring him with enthusiasm. The hierophant then proceeds to unveil the mysteries. He launches out into a splendid description of the original state of mankind; when health was their ordinary state, when meat, and drink, and shelter, were their only wants. At that period (says he) men enjoyed the most inestimable blessings, *equality and liberty;* they enjoyed them to their utmost extent: but when the wandering life ceased, and property started into existence; when arts and sciences began to flourish; when a distinction of ranks and civil associations were established, "liberty was ruined in its foundation, and equality disappeared. The world then ceased to be a great family, to be a single empire; the great bond of nature was rent asunder." Wants now increased, and the weak imprudently submitted to the wise or the strong, that they might be protected. As the submission of one person to another arises from wants, it ceases when the wants no longer exist. Thus the power of a father is at an end when the child has acquired his strength. Every man, having attained to years of discretion, may govern himself; when a whole nation, therefore, is arrived at that period, there can exist no farther plea for keeping it in wardship.

Such a state as that of civil society, is then represented as incompatible with the practice of virtue. "With the division of the globe, and of its states, benevolence (says the hierophant) was restrained within certain limits, beyond which it could no longer be extended. Patriotism was deemed a virtue; and he was styled a patriot who, partial towards his countrymen, and unjust to others, was blind to the merits of strangers, and believed the very vices of his own country to be perfections. We really beheld (continues he) patriotism generating localism, the confined spirit of families, and even egoism. Diminish, reject that love of country, and mankind will once more learn to know and love each other as men. Partiality being cast aside, a union of hearts will once more appear, which will expand itself over the globe."

These unphilosophical declamations, enthusiastically pronounced, at length make the proselyte exclaim, in unison with his master, "Are such then the consequences of the institution of states, and of civil society? O folly! Oh people! that you did not foresee the fate that awaited you; that you should yourselves have seconded your despots in degrading human nature to servitude, and even to the condition of the brute!"

Having wrought up the proselyte to this pitch of frenzy, and enumerated all the evils which, according to Weishaupt, arise from political association, the hierophant comes to reveal the means by which the grievances of the human race may be redressed. "Providence (he says) has transmitted the means to us of secretly meditating, and at length operating, the salvation of human kind. These means are the secret schools of philosophy. These schools have been in all ages the archives of nature, and *of the rights of man.* These schools shall one day retrieve the fall of human nature, and PRINCES AND NATIONS SHALL DISAPPEAR FROM THE FACE OF THE EARTH; and that without any violence. Human nature shall form one great family, and the earth shall become the habitation of the man of reason. *Reason shall be the only book of laws, the sole code of man.* This is one of our *grand mysteries.* Attend to the demonstration of it; and learn how it has been transmitted down to us."

This pretended demonstration makes part of the same sophistical harangue; and consists in panegyrics on the dignity of human nature; in a baseless morality; and in a scandalous perversion of the Christian scriptures, with a blasphemous account of the ministry of the Saviour of the world.

"What strange blindness (continues the hierophant) can have induced men to imagine, that human nature was always to be governed as it has hitherto been? Where is the being, who has condemned men, the best, the wisest, and the most enlightened men, to perpetual slavery? Why should human nature be bereft of its most perfect attribute, that of governing itself? Why are those persons to be always led who are capable of conducting themselves? Is it then impossible for mankind, or at least the greater part of them, to come to majority? Are we then fallen so low as not even to feel our chains, as to hug them, and not cherish

Illuminati. cherish the flattering hope of being able to break them, and recover our liberty? No; let us own that it is not impossible to attain UNIVERSAL INDEPENDENCE."

28
The illuminees enemies to commerce.

The principal means which Weishaupt offers to his adepts for the conquest of this land of promise, is to diminish the wants of the people; and accordingly the code denounces eternal war with every species of commerce. Hence the hierophant proceeds to inform the candidate, that he who wishes to subject nations to his yoke, need but to create wants, which he alone can satisfy." "Confer (says he) upon the *mercantile tribe* some rank or some authority in the government, and you will have created perhaps the most formidable, the most despotic of all powers. He, on the contrary, who wishes to render mankind free, teaches them how to refrain from the acquisition of things which they cannot afford: he enlightens them, he infuses into them bold and inflexible manners. If you cannot diffuse, at the same instant, this degree of light among all men, at least begin by enlightening yourself, and by rendering yourself better. The mode of diffusing universal light is, not to proclaim it at once to the whole world, but to begin with yourself; then turn to your next neighbour: you two can enlighten a third and a fourth: let these in the same manner extend and multiply the number of the children of light, until *numbers and force shall throw power into your hands*. You will soon acquire sufficient force to *bind the hands of your opponents, to subjugate them*, and to stifle wickedness in the embryo;" *i. e.* you will soon be able to stifle every principle of law, of government, of civil or political society, whose very institution, in the eyes of an illuminee, is the germ of all the vices and misfortunes of human nature.

29
Their morality;

The hierophant, continuing to insist on the necessity of enlightening the people to operate the grand revolution, seems to be apprehensive that the candidate may not yet clearly conceive the real plan of this revolution, which is in future to be the sole object of all his instructions. Let your instructions and lights be universally diffused; so shall you render mutual security universal; *and security and instruction will enable us to live without prince or government*. The instruction which is to accomplish this great end, is instruction in *morality*, and *morality alone;* for "*true morality* is nothing else than the art of teaching men to *shake off their wardship*, to attain the age of manhood; and thus to need neither princes nor governments. The morality which is to perform this miracle, is not a morality of vain subtleties. It is not that morality which, degrading man, renders him careless of the goods of this world, forbids him the enjoyment of the innocent pleasures of life, and inspires him with the hatred of his neighbour. *Above all*, it must *not* be that morality which, adding to the miseries of the miserable, throws them into a state of pusillanimity and despair, *by the threats of hell and the fear of devils*. It must be a divine doctrine, such as Jesus taught to his disciples, and of which he gave the real interpretation in his secret conferences."

30
And blasphemies of Christ.

The impious hierophant then proceeds, with matchless blasphemy, to represent the Redeemer of mankind as teaching, like the Grecian sophists, an exoteric and an esoteric doctrine. He describes him as the grand master of the illuminees; and affirms, that the object of his *secret*, which is lost to the world in general, has been preserved in their mysteries. It was "to reinstate mankind in their ORIGINAL EQUALITY and LIBERTY, and to prepare the means. This explains in what sense Christ was the *Saviour and Redeemer of the world*. The doctrine of original sin, of the fall of man, and of his regeneration, can now be understood. The state of pure nature, of fallen or corrupt nature, and the state of grace, will no longer be a problem. Mankind, in quitting their state of *original liberty, fell* from the state of nature, and *lost their dignity*. In their civil society, under their governments, they no longer live in the state of *pure* nature, but in that of *fallen* and *corrupt* nature. If the moderating of their passions, and the diminution of their wants, reinstate them in their primitive dignity, that will really constitute their *redemption* and their *state of grace*. It is to this point that morality, and the most perfect of all morality, that of Jesus, leads mankind. When at length this doctrine shall prevail throughout the world, the reign of the good and of the elect shall be established."

This language (as M. Barruel observes) is surely not enigmatical; and the proselyte who has heard it without shuddering, may flatter himself with being worthy of this Antichristian priesthood. He is led 31
back to the porch, where he is invested with a white Preparatory rites to
tunic and broad scarlet belt of silk. The sleeves of the tunic, which are wide, are tied in the middle and at the extremities with ribbons likewise of scarlet; and the candidate is recalled into the temple of mysteries. He is met by one of the brethren, who does not permit him to advance till he has declared "whether he perfectly understands the discourse which has been read to him; whether he has any doubts concerning the doctrines taught in it; whether his heart is penetrated with the sanctity of the principles of the order; whether he is sensible of the call, feels the strength of mind, the fervent will, and all the disinterestedness requisite to labour at the *grand undertaking;* whether he is ready to make a sacrifice of *his will*, and to suffer himself to be *led* by the most *excellent superiors of the order*."

The rites of the preceding degree were in impious de- 32
rision of the sacrament of the Lord's supper; those of the Initiation
presentare an atrocious mimicry of sacerdotal ordination; to the
at which, as every one knows, the Lord's supper is like- priesthood.
wise celebrated. A curtain is drawn, and an altar appears with a crucifix upon it. On the altar is a bible; and the ritual of the order lies on a reading desk, with a censer and a phial full of oil beside it. The dean, or president, who acts the part of a bishop, blesses the candidate, cuts hair from the crown of his head, anoints him, clothes him in the vestments of the priesthood, and pronounces prayers after the fashion of the order. He presents him with a cap, saying, "Cover thyself with this cap; it is more precious than the royal diadem." The mock communion is then distributed; and it consists of milk and honey, which the dean gives to the proselyte, saying, "This is that which nature gives to man. Reflect how happy he would still have been, if the desire of superfluities had not, by depriving him of a taste for such simple food, multiplied his wants, and poisoned the balm of life."

The

Illuminati.

The ceremonies are terminated by delivering to the epopt that part of the code which relates to his new degree.

33 Duties of the prieſt or epopt.

Among the inſtructions which it contains, the following are more particularly worthy of notice. The epopt, ſays the code, "will take care that the writings of the members of the order ſhall be cried up, and that the trumpet of fame ſhall be ſounded in their honour. He will alſo find means of *hindering the reviewers from caſting any ſuſpicions* on the writers of the ſect." He is likewiſe inſtructed to *bribe* the common people into the intereſts of the order, and to corrupt their minds, by getting poſſeſſion of ſchools and other ſeminaries of learning. But "if it be neceſſary for us to be maſters of the ordinary ſchools (ſays the impious legiſlator), of how much more importance will it be to gain over the *Eccleſiaſtic ſeminaries and their ſuperiors!* With them we gain over the chief part of the country; we acquire *the ſupport of the greateſt enemies to innovation;* and the grand point of all is, that through *the clergy* we become *maſters of the middle and lower claſſes of the people.*"

34 Qualifications for the degree of regent.

From the degree of epopt or prieſt are choſen the *regents* or *prince illuminees.* On making this choice, ſays the code, three things of the utmoſt conſequence are to be obſerved. "*1ſt,* The greateſt reſerve is neceſſary with reſpect to this degree: *2dly,* Thoſe who are admitted into it, muſt be as much as poſſible *free men,* and *independent of princes: 3dly,* They muſt have clearly manifeſted their *hatred of the general conſtitution,* or the *actual ſtate* of mankind; and have ſhewn how evidently they wiſh for a *change in the government of the world.*" If theſe requiſites be found in an epopt who aſpires to the degree of regent, ſix preliminary queſtions are put to him; of which the obvious meaning is to diſcover, whether he deems it lawful and proper to teach ſubjects to throw off the authority of their ſovereigns, or, in other words, to deſtroy every king, miniſter, law, magiſtrate, and public authority on earth.

When theſe queſtions are anſwered to the ſatisfaction of his examiner, he is informed, "that as, in future, he is to be entruſted with papers belonging to the order of far greater importance than any which he has yet had in his poſſeſſion, it is neceſſary that the order ſhould have farther ſecurities. He is, therefore, commanded to make his *will,* and inſert a clauſe with reſpect to any private papers which he may leave, in caſe of ſudden death. He is to get a formal or juridical receipt for that part of his will from his family, or from the public magiſtrate; and he is to take their promiſes in writing, that they are to fulfil his intentions." This precaution being taken, and the day fixed for his inauguration, he is admitted into an antechamber hung with black, where he ſees a ſkeleton, elevated two ſteps, with a crown and ſword lying at its feet. Having given up the written diſpoſitions, &c. reſpecting his papers, his hands are loaded with chains as if he were a ſlave, and he is left to his meditations. A dialogue then takes place between his introducer and the provincial, who is ſeated on a throne in a ſaloon adjoining. It is in a voice loud enough to be heard by the candidate, and conſiſts of various queſtions and anſwers; of which the following may ſerve for a ſpecimen:

Illuminati.

35 Admiſſion to this degree.

Prov. Who has reduced him to this ſtate of ſlavery?

Anſ. by the Introd. SOCIETY, GOVERNMENTS, the SCIENCES, and falſe RELIGION.

Prov. And he wiſhes to caſt off this yoke, to become a ſeditious man and a rebel?

Anſ. No; he wiſhes to unite with us, to JOIN IN OUR FIGHTS AGAINST THE CONSTITUTION OF GOVERNMENTS, the corruption of morals, and the profanation of religion. He wiſhes, through our means, to become POWERFUL, that he may attain the GRAND ULTIMATUM.

Prov. Is he ſuperior to *prejudices?* Does he prefer the *general intereſt of the univerſe* to that of *more limited aſſociations?*

Anſ. Such have been his promiſes.

Prov. Aſk him, whether the ſkeleton which is before him be that of a *king,* a *nobleman,* or a *beggar?*

Anſ. He cannot tell; all that he ſees is, that this ſkeleton was a man like us; and the character of *man* is all that he attends to.

After a great deal of inſidious mummery like this, the epopt is admitted to the degree of prince; but before his inveſtiture with the inſignia of that order, he is exhorted to be *free, i. e.* to be a man, and a man who knows how to *govern himſelf;* a man who knows his duty, and his *impreſcriptible rights;* a man who ſerves the *univerſe alone;* whoſe actions are ſolely directed to the *general benefit* of the world and of human nature. "Every thing elſe (ſays the provincial) is INJUSTICE." A long panegyric is then made on the happineſs which will be experienced by mankind, when *every father* of a family ſhall be *ſovereign* in his tranquil cot! when he that wiſhes to invade theſe *ſacred rights* ſhall not find an aſylum on the face of the earth! when idleneſs ſhall be no longer ſuffered; and when *the clod of uſeleſs ſciences ſhall be caſt aſide* (c)!

36 [illegible]

The *ſign* of this degree conſiſted in extending out the arms to a brother with the hands open: the *grip* was to ſeize the brother by the two elbows, as it were to prevent him from falling; and the *word* was REDEMPTION! The epopt was inveſted with his principality by receiving a buckler, boots, a cloak, and a

hat;

(c) This will naturally ſurpriſe our readers; but it could not ſurpriſe him to whom it was addreſſed; for when candidate for the prieſthood, he had been aſked, "Do the ſciences which men cultivate furniſh them with real lights? Are they conducive to real happineſs? Are they not, on the contrary, the offspring of numberleſs wants, and of the unnatural ſtate in which men live? Are they not the crude inventions of crazy brains?" There were, however, to be academies for the cultivation of ſuch ſciences as ſuited the deſigns of the order. Each academy was to conſiſt of nine epopts, of whom ſeven were to preſide reſpectively over ſo many departments of ſcience, whilſt the other two were to officiate as ſecretaries. One of the departments included the occult ſciences, to which belonged the art of *raiſing the ſeals of the letters* of all who belonged not to the order, and of ſecuring their own letters againſt ſimilar practices!!

hat; and on receiving the boots, he was deſired to *fear no road* which might lead to the propagation or diſcovery of *happineſs*. Thus decorated, the prince illuminee received the *fraternal embrace*, and heard the inſtructions for his new degree.

One would think that the adept had now arrived at the very acmé of profaneneſs, and treaſonable conſpiracy. He has been initiated in myſteries which burleſque Chriſtianity and its Divine Author, and at the ſame time vow vengeance againſt all government, all law, and all ſcience; yet Weiſhaupt, in a letter to Cato Zwack, his incomparable man, ſays, that he has compoſed four degrees above that of regent, or prince-illuminee; with reſpect even to the *loweſt* of which, his degree of prieſt will be found no more than child's play. "The ritual of theſe degrees, (ſays he), I never ſuffer to go out of my hands. It is of too ſerious an import; it is the key of the ancient and modern, the religious and political, hiſtory of the univerſe."

This caution of the chief conſpirator has deprived us of the power to give ſo particular an account of theſe degrees as we have done of the preceding; but the Abbé Barruel aſſures us that they were reduced to two, viz. that of Magus, and that of the Man-king; and that theſe two conſtituted the GREATER MYSTERIES. When the adept was admitted to the degree of *magus*, he was illuminized only in philoſophy and religion; when to that of *man-king*, new lights were given him reſpecting property, and every ſpecies of political aſſociation. The Abbé quotes a paſſage from *the Critical hiſtory of all the degrees of illuminiſm*, written by a man of honour, who had paſſed through them all, which will give the reader a ſufficient idea of the object of theſe laſt degrees.

37 Objects of the degrees of magus and man-king.

"With reſpect to the two degrees of *magus* and of *man-king* (ſays this writer), there is no reception, that is to ſay, there are no ceremonies of initiation. Even the elect are not permitted to tranſcribe theſe degrees; they only hear them read, and that is the reaſon why I do not publiſh them with this work. The firſt is that of Magus, called alſo philoſopher. It contains the fundamental principles of Spinoziſm. Here every thing is *material;* God and the world are but one and the ſame thing; all religions are inconſiſtent, chimerical, and the invention of ambitious men."

That this is the doctrine of Spinoza, and that Spinoza was an atheiſt, is moſt certain; but though nothing can be *eſſentially* worſe than atheiſm, we are ſtrongly inclined to ſuſpect that, at the initiation of the Magus, expreſſions muſt have been uſed more *ſhocking at leaſt to the ear* than the philoſophic jargon of the apoſtate Jew. It is long ſince the philoſophy of Spinoza was in Germany recommended from the preſs (ſee Spinoza, *Encycl.);* it is but very lately that a profeſſor in the univerſity of Jena publiſhed a book, in which he teaches that there is *no God*, and that we abſurdly give that title to *the relations of Nature* (D); and ſomething approaching ſo near to atheiſm had been communicated to the adept when he was admitted to the prieſthood, that we are perſuaded Weiſhaupt muſt have alluded to *language* at leaſt different from that in which Spinoza taught his dark doctrines, and that language, accompanied perhaps with impious and audacious geſtures, when he ſaid that, compared with his higher myſteries, his degree of prieſt was but child's play.

What gives ſome degree of probability to this conjecture, if it be nothing more, is the following fact related by the Abbé Barruel. During the French revolution (ſays that able and well informed writer), a comedian appeared (E), dreſſed in the ſacerdotal robes of the illuminees, and perſonally defying Almighty God. "No! (ſaid the impious wretch) thou doſt not exiſt. If thou haſt power over the thunderbolts, graſp them; aim them at the man who dares ſet thee at defiance in the face of thy altars. But no! I blaſpheme thee, and I ſtill live. No! thou doſt not exiſt." It will be ſeen by and bye, that the chiefs of the revolution, and even numbers of their tools, were illuminized; and it is improbable that this blaſphemer, who was arrayed in the inſignia of the epopts, made uſe of the language and geſtures of the higher myſteries? Whether it be or not, M. Barruel has proved, even from the writings of Weiſhaupt himſelf, that the magi were at leaſt atheiſts of the ſchool of Spinoza. 38 Atheiſm and

"The ſecond degree of the grand myſteries, called the *Man-king*, teaches (according to the author of the Critical Hiſtory), that every inhabitant of the country or town, every father of a family, is ſovereign, as men formerly were in the times of the patriarchial life, to which mankind is once more to be carried back; that in conſequence all authority and all magiſtracy muſt be deſtroyed."

This may appear to be nothing more than what the adept has been already taught in the leſſer myſteries; 39 Savagiſm.
and it is in fact nothing more than that to which he muſt have ſeen theſe myſteries tending; but the reader underſtands not the language of the illuminees, if he ſuppoſes that, by the patriarchal ſtate, they mean ſuch a ſtate as that of the patriarchs of the Old Teſtament. No! their patriarchal ſtate is the fancied ſavage ſtate of the atheiſtical philoſophers of Greece and Rome, when mankind had neither property nor fixed habitation. This is evident from one of the diſcourſes of the hierophant; in which he tells the adept, that it would have been happy for man "had he known how to preſerve himſelf in the primitive ſtate in which Nature had placed him! But ſoon the unhappy germ developed itſelf in his heart, and reſt and happineſs diſappeared. As families multiplied, the neceſſary means of ſubſiſtence began to fail. *The Nomade or roaming life ceaſed; property began; men choſe fixed habitations; agriculture brought them together;* LIBERTY WAS RUINED IN ITS FOUNDATIONS, AND EQUALITY DISAPPEARED."

To reſtore that liberty and equality, therefore, which is the ultimate object of the order, and conſtitutes the Man-king, all property muſt be aboliſhed, every houſe burnt, as well the cottage of the peaſant as the palace of the prince; and mankind muſt once more inhabit woods and caverns without clothes and without fire, and ſally out occaſionally to encounter their fellow-brutes,

(D) We learned this from the letter already quoted in note (A.)

(E) He does not ſay where this appearance was made; but the circumſtances related lead us to ſuppoſe that it was in a church.

Illuminati.

brutes, and to search for food among the wild herbs of the desert. According to Mochus the Phenician, and the Greek philosophers of this hopeful school, this was the original state of man* ; and to this state it was the object of Weishaupt and his adepts to reduce man again. Hence we hear them lavishing the most rapturous encomiums on the Goths and Vandals who over-ran the Roman empire, annihilated the arts, put a stop to agriculture, and burnt the towns and villages of civilized Europe! It was thus, according to the illuminees, that those barbarians regenerated mankind: but the regeneration was not complete; for the Goths and Vandals could not preserve themselves from the contagion of civil life; and their fall from savagism to science drew from Weishaupt's hierophants the most piteous lamentations!

* See Doig's *Letter on the Savage State.*

40
The last secret of the order.

The last secret communicated to the most favoured adepts was the novelty of the order. Hitherto their zeal had been inflamed, and their respect demanded to an institution pretended to be of the highest antiquity. The honour of instituting the mysteries had been successively attributed to the children of the Patriarchs, to ancient philosophers, even to Christ himself, and to the founders of the masonic lodges (see MASONRY in this *Suppl.*) But now the time is come when the adept, initiated in the higher mysteries, is supposed to be sufficiently enthusiastic in his admiration of the order, to be entrusted with the history of its origin. Here then they inform him, that this secret society, which has so artfully led him from mystery to mystery; which has with such persevering industry rooted from his heart every principle of religion, all love of his country, and affection for his family; all pretensions to property, to the exclusive right to riches, or to the fruits of the earth;—this society, which has taken so much pains to demonstrate the tyranny and despotism of all laws human and divine, and of every government, whether monarchical, aristocratical, or republican; which has declared him free, and taught him that he has no sovereign on earth or in heaven; no rights to respect in others, but those of perfect equality, of savage liberty, and of the most absolute independence; that this society is not the offspring of an ignorant and superstitious antiquity, but of modern philosophy; in one word, that the true father of illuminism is no other than Adam Weishaupt, known in the society by the name of SPARTACUS! This *important* secret, however, remained a mystery even to the greater part of the *magi* and the *man-kings*, being revealed only to the grand council of *areopagites*, and to a few other adepts of distinguished merit.

41
Proposal for a female order,

So zealously was the order bent upon propagating its execrable principles through the whole world, that some of the chiefs had planned an order of female adepts, in subserviency to the designs of the men. "It will be of great service, (says *Cato*-Zwack), it will procure us both information and money, and will suit charmingly the taste of some of our truest members, who are lovers of the sex." An assessor of the Imperial chamber at Wetzlar, of the name of Dittfurt, but known among the illuminees by that of *Minos*, expressed even his despair of ever bringing men to the grand object of the order without the support of female adepts; and he makes an offer of his own wife and his four daughters-in-law to be first initiated. This order was to be subdivided into two classes, each forming a separate society, and having different secrets. The first was to be composed of virtuous women; the second of the wild, the giddy, and the voluptuous. The brethren were to conduct the first, by promoting the reading of good books; and to train the second to the arts of *secretly gratifying their passions*. The wife of an adept named Ptolemy Magus was to preside over one of the classes; which (says Minos) will become, under her management and his, a very pretty society. "You must contrive pretty degrees, and dresses, and ornaments, and elegant and decent rituals. No man must be admitted. This will make them more keen, and they will go much farther than if we were present, or than if they thought that we knew of their proceedings. Leave them to the scope of their own fancies, and they will soon invent mysteries which will put us to the blush, and mysteries which we can never equal. They will be our great apostles. Reflect on the respect, nay, the awe and terror, inspired by the female mystics of antiquity. Ptolemy's wife must direct them, and she will be instructed by Ptolemy; and my step-daughters will consult with me. We must always be at hand to prevent the introduction of any improper question. We must prepare themes for their discussion: thus we shall confess them, and inspire them with our sentiments. No man, however, must come near them. This will fire their roving fancies, and we may expect rare mysteries!"

But notwithstanding all the plans and zeal of this profligate wretch and others of the fraternity, it does not appear that the General *Spartacus* ever consented to the establishment of the sisterhood. He supplied, however, the want of such an institution, by secret instructions to the regents, on the means of making the influence of women over men subservient to the order, without entrusting them with any of the secrets. "The fair sex (says he) having the greatest part of the world at their disposal, no study is more worthy the adept than the *art of flattery*, in order to gain them. They are all more or less led by vanity, curiosity, pleasure, or the love of novelty. It is on that side, therefore, they are to be attacked, and by that to be rendered subservient to the order." That Weishaupt's sagacity had not on this occasion forsaken him, is very evident; since it has been proved that the German fair, who were the correspondents of the illuminees, welcomed the French invaders of their native country.* Nay, so lately as last winter, our correspondent in Saxony heard several of these illuminized ladies express a wish that the French might invade and conquer England; for then, said they *tea and coffee would be cheaper!* 42

42
Rejected by Spartacus.

* Dr Robison's *Proofs of a Conspiracy.*

It is not enough for the founder of a sect of conspirators to have fixed the precise object of his plots. His accomplices must form but one body, animated by one spirit; its members must be moved by the same laws, under the inspection and government of the same chiefs. A full account of the government of Weishaupt's order will be found in the valuable work of Abbé Barruel; our limits permit us to give only such a general view of it as may put our readers on their guard against the secret machinations of these execrable villains, whose lodges are now recruiting, under different denominations, in every country in Europe.

Wherever illuminism has gained a footing, as the means of of subordination, there is a general division of command as well as of locality. The *candidates* and *novices* are each

43 Subordination of the illuminees.

under the direction of his own insinuator, who introduces him into the *Minerval lodges*; each *Minerval lodge* has a superior from among the preparatory class, under the inspection of the intermediary class. So many lodges constitute a district, under the direction of a superior, whom the order calls *dean*. The dean is subjected to the *provincial*, who has the inspection and command of all the lodges and deaneries of the province. Next in order comes the *national superior*, who has full power over all within his nation, provincials, deans, lodges, &c. Then comes the supreme council of the order, or the *areopagites*, over which presides the *general* of illuminism. Thus has the order formed within itself a supreme tribunal, to whose inquisition all nations are to be subjected. The areopagites, consisting of twelve fathers of the order, with the general at their head, form the centre of communication with all the national superiors on earth; each *national* is the centre of one particular nation; the *provincial*, of one province; the *dean*, of the lodges within his deanery; the *minerval master*, of his academy; the *venerable*, of his masonic lodge; and the *insinuator* or *recruiter*, of his *novices* and *candidates*.

44 Their mode of correspondence;

The higher degrees (says Weishaupt in one of his instructions to the regents) must always be hidden from the lower. The simple illuminee, therefore, corresponds with his immediate superior, knowing perhaps no other member of the order; the latter, with his dean; and thus gradually ascending to the national superiors, who alone are acquainted with the residence of the areopagites, as they again are with the name and residence of the general. Any member, however, of the inferior degrees, may occasionally correspond with his unknown superiors, by addressing his letters *Quibus licet*; and in these letters he may mention whatever he thinks conducive to the advancement of the order. If he be a novice, he may in these letters inform his superiors how his instructor behaves to him, or may draw the character of any person whatever. When the letter of any adept contains secrets, or complaints which he chuses to conceal from his immediate superior, he directs it *Soli* or *Primo*; and then it can be opened only by the *provincial*, the *national superior*, the *areopagites*, or the *general*, according to the rank of the writer, which is by some contrivance unknown to M. Barruel, indicated on the outside of the letter. The *provincial* opens the letters of the *minor* and *major* illuminees which are directed *Soli*; the *Quibus licets* of the epopts; and the *Primos* of the novices; but he cannot open either the *Primo* of the minerval, the *Soli* of the Scotch knight, or the *Quibus licet* of the regent. He can only form a conjecture as to the persons who open his own letters, and those which he is not permitted to open himself.

45 And of giving importance to their order.

When it considered, that by one of Weishaupt's statutes, the provincial has in each chapter or district a confidential epopt, who is his *secret censor* or *spy*; that these spies are to insinuate themselves into all companies, and collect *anecdotes of secret history*; that the historian of the province is to insert these anecdotes into a journal kept for that purpose; and that the provincials are obliged to forward the contents of these journals to the high superiors of the order—some notion may be formed of the influence of the general and areopagites in every country into which illuminism has found its way. "The means of acquiring an ascendancy over men (says Weishaupt) are incalculable. Who could enumerate them all? They must vary with the disposition of the times. At one period, it is a taste for the marvellous that is to be wrought upon. At another, the lure of secret societies is to be held out. For this reason, it is very proper to make your inferiors believe, without telling them the real state of the case, that all other secret societies, particularly that of *Freemasonry, are secretly directed by us.* Or else, and IT IS REALLY THE FACT IN SOME STATES, THAT POTENT MONARCHS ARE GOVERNED BY OUR ORDER. When any thing remarkable or important comes to pass, hint that it *originated with our* order. Should any person by his merit acquire a great reputation, let it be generally understood that *he is one of us*.

46 By every means, good or bad.

"If our order cannot establish itself in any particular place, with all the forms and regular progress of our degrees, *some other form must be assumed.* Always have *the object* in view; that is the essential point. No matter what *the cloak* be, provided you succeed; *a cloak*, however, *is always necessary*, for *in secrecy our strength lies.* The INFERIOR LODGES OF FREEMASONRY ARE THE MOST CONVENIENT CLOAKS for our GRAND OBJECT; because the world is already familiarized with the idea, that *nothing of importance* or *worthy of their attention can spring from masonry.*" No artifice, however, is to be left untried. "You may attend large and commercial towns during the times of fairs in different characters; as *a merchant, an officer, an abbé*. Everywhere you will personate an extraordinary man, having important business on your hands; but all this must be done with a great deal of *art and caution*, lest you should have the appearance of an adventurer. You may write your orders with a *chymical preparation of ink*, which *disappears after a certain time.* Never lose sight of the *military schools*, of the *academies, printing presses, libraries, cathedral chapters*, or *any public establishments* that can influence *education* or *government*. Let our regents perpetually attend to the various means, and form plans, for MAKING US MASTERS *of all these establishments.* When an author sets forth principles true in themselves, but which do not as yet suit *our general plan of education for the world*, or principles, the publication of which is premature; every effort must be made to *gain over the author*: but should all our attempts fail, and we should prove unable to entice him into the order, *let him be discredited by every possible means.*"

Of their methods of discrediting authors, one has come to our knowledge, which must be interesting to some of our readers. Dr Robison's work, entitled *Proofs of a Conspiracy*, &c. which first unmasked these hypocrites in this country, found its way into Germany, and was translated into the German language, and exposed to sale at the Leipsic fairs. The illuminees, under the disguise of *merchants* and *abbés*, attended, and bought up the whole impression, which they committed to the flames. A second edition was published, and it shared the same fate (F). This was a more compendious way of answering the learned author

(F) This information was communicated to us by a gentleman of character, who was at Leipsic when the

Illuminati.

thor than that which has been adopted by the Jacobin journalists in London; but perhaps it may convince the readers of these journals, that the Doctor has not so far mistaken the sense of the writings of *Philo* and *Spartacus*, as their illuminized masters wish them to believe.

When these arts of disseminating the disorganizing and impious principles of the order are duly considered, and when it is remembered that its emissaries dare not disobey a single injunction of the high superiors, without exposing themselves to poison, or to the daggers of a thousand unseen assassins, no man can be surprised to learn that the illuminees contributed greatly to the French revolution. The philosophers of France had indeed prepared the public mind for embracing readily the doctrines of illuminism; and so early as 1782, *Philo* and *Spartacus* had formed the plan of illuminizing that nation; but they were afraid of the vivacity and caprice of the people, and extended not their attempts, at that time, beyond Strasbourg. Already, however, there existed some adepts in the very heart of the kingdom; and the Marquis de Mirabeau, when ambassador at the court of Berlin, was initiated at Brunswick by a disciple of Philo Knigge's. On his return to France he began to introduce the new mysteries among his masonic brethren.

47 Illuminism of France

The state of free masonry was at that time peculiarly adapted to the views of the conspirators. The French had engrafted on the old and innocent British masonry a number of degrees gradually rising above each other, to the very mysteries of illuminism itself (See MASONRY, in this *Suppl.*). These were called the *philosophical* degrees, and comprehended the *knights of the sun*, the higher *Rosicrucians*, and the *knights Kadosh*. At the head of all these societies, whether ancient or modern, were three lodges at Paris, remarkable for the authority which they exercised over the rest of the order, and Philip of Orleans was the grand-master. So early as the year 1787, France contained 282 towns, in which were to be found regular lodges under the direction of that execrable wretch. He increased their number, by introducing to the *masonic* mysteries the lowest of the rabble, as well as those French guards whom he destined to the subsequent attack of the bastile, and to the storming of the palace of his near relation and royal master. In every country town and village lodges were open for assembling the workmen and peasantry, in hopes of heating their imaginations with the sophisticated ideas of equality and liberty, and the rights of man; and it was then that Mirabeau invited a deputation from the order of Weishaupt, which very quickly diffused the light of illuminism through the whole kingdom. Instead of *Spartacus*-Weishaupt, *Cato*-Zwack, and *Philo*-Knigge, we find wielding the firebrands of revolution in the capital of France, *Philip of Orleans*, *Mirabeau*, *Syeyes*, and *Condorcet*. The day of general insurrection was fixed by these miscreants for the 14th of July 1789. At the same hour, and in all parts of France, the cries of *equality* and *liberty* resounded from the lodges. The Jacobin clubs were formed; and hence sprung the revolution, with all its horrors of atheism, murder and massacre!

48 By means of free masonry.

In support of this account of the illuminees we have not loaded our margin with authorities; because our detail has been taken wholly from the valuable works of Abbé Barruel and Dr Robison, to which we refer our readers for much curious information that our limits do not permit us to give. We cannot, however, conclude the article, without making some remarks on that specious principle by which the conspirators have deluded numbers, who abhor their impieties, and who would not go all their length, even in rebellion; we mean the maxim, that "it is our duty to love all men with an equal degree of affection, and that any partial regard for our country, or our children, is unjust."

That this maxim is false, every *Christian* knows, because he is enjoined to "do good indeed unto all men, but *more especially* to them who are of the household of faith;" because he is told that "if any man provide not for his *own*, and especially for those of his *own house*, he hath denied the faith, and is worse than an infidel;" because his divine master, immediately after resolving all duty into the love of God and man, delivers a parable to shew, that we neither can, nor ought to love all men *equally*; and because the same Divine Person had one disciple whom he loved more than the rest. But we wish those *philosophers*, who talk perpetually of *the mechanism* of the human mind, and at the same time affect to have no *partial* fondness for any individual, but to love all with the same degree of *rational* affection, to consider well whether such philanthropy be consistent with what they call (very improperly indeed) *mechanism*. If this mechanism be (as one of them says it is) nothing more than *attraction* and *repulsion*, we know that it *cannot* extend with equal force over the whole world; because the force of attraction and repulsion varies with the distance. If by this absurd phrase, they mean a set of *instinctive* propensities, or feelings, we know that among savages, who are more governed by instinct than civilized men, philanthropy is a feeling or propensity of a very limited range. If they believe all our passions to originate in self love, then is it certain that our philanthropy must be progressive; embracing first, and with strongest ardour, our relations, our friends and our neighbours; then extending gradually through the society to which we belong; then grasping our country, and last of all the whole human race. Perhaps they may say that reason teaches us to love all men equally, because such equal love would contribute most to the sum of human happiness. This some of them indeed have actually said; but it is what no man of reflection can possibly believe. Would the sum of human happiness be increased, were a man to pay no greater attention to the education of his own children than to the education of the children of strangers? were he to do nothing more for his aged and helpless parents than for any other old person whatever? or were he to neglect the poor in his neighbourhood, that he might relieve those at the distance of 1000 miles? These questions are too absurd to merit a serious answer.

49 Reflections on the fundamental principles of illuminism;

When a man, therefore, boasts of his universal benevolence, declaring himself ready, without fee or reward, to sacrifice every thing dear to him for the benefit

---

two impressions of the book were thus disposed of. The Abbé Barruel's work has no doubt been answered in the same way, though we cannot say so upon the same authority.

fit of strangers whom he never saw; and when he condemns, in the cant phrase of faction, that narrow policy which does not consider the whole human race as one great family—we may safely conclude him to be either a consummate hypocrite who loves none but himself, or a philosophical fanatic, who is at once a stranger to his duty and to the workings of his own heart.

50 Exemplified in the conduct of the illuminees.

If this conclusion require any farther proof, we have it in the conduct of Weishaupt and his areopagites. In the hand writing of *Cato*, his *incomparable man*, was found the description of a strong box, which, if forced open, would blow up and *destroy its contents;* several receipts for *procuring abortion;* a composition which *blinds or kills* when spurted in the face; *tea* for procuring abortion; *Herbæ quæ habent qualitatem deleteream;* a method for filling a bed chamber with *pestilential vapours;* how to take off impressions of seals, so *as to use them afterwards as seals;* a receipt *ad excitandum furorem uterinum;* and a dissertation on *suicide*. Would genuine philanthropists have occasion for such receipts as these? No! the order which used them was founded in the most consummate villany, and by the most detestable hypocrite. The incestuous Weishaupt seduced the widow of his brother, and solicited poison and the dagger to murder the woman whom he had fondly pressed in his arms. "Execrable hypocrite (says M. Barruel), he implored, he conjured both art and friendship, to destroy the innocent victim, the child, whose birth must betray the morals of his father. The scandal from which he shrinks, is not that of his crime: it is the scandal which, publishing the depravity of his heart, would deprive him of that authority by which, under the cloak of virtue, he plunged youth into vice and error. *I am on the eve* (says he) *of losing that reputation which gave me so great authority over our people: My sister-in-law is with child. I will hazard a desperate blow, for I neither can nor will lose my honour.*" Such is the benevolence of those who, banishing from their minds all partial affection for their children and their country, profess themselves to be members of one great family, the family of the world!

IMAGINARY QUANTITIES, or *Impossible Quantities*, in algebra, are the even roots of negative quantities; which expressions are Imaginary, or impossible, or opposed to real quantities; as $\sqrt{-aa}$, or $\sqrt[4]{-a^4}$, &c. For as every even power of any quantity whatever, whether positive or negative, is necessarily positive, or having the sign $+$, because $+$ by $+$, or $-$ by $-$, give equally $+$; hence it follows that every even power, as the square for instance, which is negative, or having the sign $-$, has no possible root; and therefore the even roots of such powers or quantities are said to be impossible or imaginary. The mixt expressions arising from imaginary quantities joined to real ones, are also imaginary; as $a - \sqrt{-aa}$, or $b + \sqrt{-aa}$.

IMAGINARY Roots of an equation, are those roots or values of the unknown quantity, which contain some imaginary quantity. Thus, the roots of the equation $xx + aa = 0$, are the two imaginary quantities $+\sqrt{-aa}$ and $-\sqrt{-aa}$, or $+a\sqrt{-1}$ and $-a\sqrt{-1}$.

IMPACT, the simple or single action of one body upon another to put it in motion. Point of impact is the place or point where a body acts.

IMPERFECT NUMBER, is that whose aliquot parts, taken all together, do not make a sum that is equal to the number itself, but either exceed it, or fall short of it; being an abundant number in the former case, and a defective number in the latter. Thus, 12 is an abundant imperfect number, because the sum of all its aliquot parts, 1, 2, 3, 4, 6, makes 16, which exceeds the number 12. And 10 is a defective imperfect number, because its aliquot parts, 1, 2, 5, taken all together, make only 8, which is less than the number 10 itself.

IMPERIALE, a city of Chili in South-America, 6 leagues from the South Sea, having the river Cauten to the south and another river to the west, both navigable. It is situated on a rising steep neck of land, hard to be ascended. In 1600, it was taken by the Indians, after a year's siege; most of the inhabitants having perished by famine. They burnt the town, and then laid siege to Soforno. In this war Valdivia, Argol, Sancta Cruz, Chilla, and Villa Rica were taken. After which they became so confident of their strength, that they fought the Spaniards bravely, and in some measure revenged the cruelties they had committed upon their countrymen. The Spaniards afterwards built a town here called *Conception*. S. lat. 38° 42′, W. long. 73° 25′.—*Morse*.

IMPOST, in architecture, a capital or plinth, to a pillar, or pilaster, or pier, that supports an arch, &c.

Doctrine of Impulsion.

IMPULSION, is the term employed in the language of mechanical philosophy, for expressing a supposed peculiar exertion of the powers of body, by which a moving body changes the motion of another body by hitting or striking it. The plainest case of this action is when a body in motion hits another body at rest, and puts it in motion by the stroke. The body thus put in motion is said to be IMPELLED by the other; and this way of producing motion is called IMPULSION, to distinguish it from PRESSION, THRUSTING, or PROTRUSION, by which we push a body from its place without striking it. The term has been gradually extended to every *change* of motion occasioned by the collision of bodies.

1 History of it.

When speculative men began to collect into general classes, the observations made during the continual exertions of our own personal powers on external bodies, in order to gain the purposes we had in view, it could not be long before they remarked, that as we, by the strength of our arm, can move a body, can stop or anyhow change its motion; so a body already in motion produces effects of the same kind in another body, by hitting it. Such observations were almost as early and as interesting as the other; and the attention was very forcibly turned to the general facts which obtained in this way of producing motion; that is, to the expiscation of the general laws of impulsion. We do not find, however, in what remains of the physical science of the ancients, that they had proceeded far in this classification. While mechanics, or the science of machines, had acquired some form, and had been the subject of successful mathematical discussion, we do not find that any thing similar had been done in the science of impulse. Yet the artillery of ancient times was very ingenious and powerful. But although Vegetius, and Ammianus Marcellinus, and Hero, describe the mechanism of these engines with great care, and frequently with mathematical skill, we see no attempts to ascertain with precision the force of the missile weapon, or to state the efficacy of the battering

Impulsion.

battering ram, by measures of the momentum, and comparison of it with the resistance opposed to it. The engineers were contented with very vague notions on these points.

Aristotle, in his 20th Mechanical Question, and Galen in some occasional observations, are the only authors of antiquity whom we recollect as treating the force of impulse as a quantity susceptible of measure. Their observations are extremely vague and trivial, chiefly directed, however, to the discrimination of the force of impulse from that of pressure.

In more modern times, great additions had already been made to the assistance we had derived from the impulsive efficacy of bodies in motion. Water-mills and wind-mills had been invented, and had been applied to such a variety of purposes, that the engineers were fast acquiring more distinct notions of the force of impulse. Naval construction was changed in such a manner, that there hardly remained any thing of the ancient rigging. The oblique action of wind and water were now found even more effective than the direct; and ships could now sail with almost any wind. All these things fixed the attention of the engineers and of the speculatist on the numberless modifications of the force of impulse.

But it soon appeared that this was a refined branch of knowledge, and required a more profound study than any other department of the science of motion. At the same time, it was equally clear, that it was also of superior importance. Mills worked by cattle, or by men's hands, were everywhere giving place to wind and water-mills; and a ship alone appeared to every intelligent mechanician to be the greatest effort of human invention, and most deserving his careful study. All these improvements in the arts of life derived their efficacy from the impulse of bodies. The laws of impulsion, therefore, became the objects of study to all who pretended to philosophical science. But this is a branch of study wholly new, and derives little assistance from the mechanical science already acquired; for that was confined to the determination of the circumstances which regulated the equilibrium of forces, either in their combined action on bodies in free space, or by the intervention of machines. But in the production of motion by impulse, the equilibrium is not supposed to obtain; and therefore its rules will not solve the most important question, " What will be the precise motion?"

Galileo, to whom we are indebted for the first discoveries in the doctrine of free motions, was also the first who attempted to bring impulsion within the pale of mathematical discussion. This he attempted, by endeavouring to state what is the force or energy of a body in motion. The very obscure reflections of Aristotle on this subject only served to make the study more intricate and abstruse. Galileo's reflections on it are void of that luminous perspicuity which is seen in all his other writings, and do not appear to have satisfied his own mind. He has recourse to an experiment, in order to discover what pressure was excited by impulsion. A weight was made to fall on the scale of a balance, the other arm of which was loaded with a considerable weight; and the force of the blow was estimated by the weight which the blow could thus start from the ground. The results had a certain regularity, by which some analogy was observed between the weights thus started and the velocity of the impulse; but the anomalies were great, and the analogy was singular and puzzling; it led to many intricate discussions, and science advanced but slowly.

2
Laws of impulsion discovered by Wallis, Wrenn, and Huyghens.

At last the three eminent mathematicians, Dr Wallis, Sir Christopher Wrenn, and Huyghens, about the same time, and unknown to each another, discovered the simple and beautiful laws of collision, and communicated them to the Royal Society of London in 1668 (Phil. Trans. n° 43—46). Sir Christopher Wrenn also invented a beautiful method of demonstrating the doctrine by experiment. The bodies which were made to strike each other were suspended by threads of equal length, so as to touch each other when at rest. When removed from this their vertical situation, and then let go, they struck when arrived at the lowest points of their respective circles, and their velocities were proportional to the chords of the arches through which they had descended. Their velocities, after the stroke, were measured, in like manner, by the chords of their arches of ascent. The experiments corresponded precisely with the theoretical doctrine.

In the mean time, this subject had keenly occupied the attention of philosophers, who found it to be of a very abstruse nature; or, which is nearer the truth, they indulged in great refinement in prosecuting the study. The first attempts to measure the impulsive force of bodies, by setting it in opposition to pressures, which had long been measured by weights, gave rise to some very refined reflections on the nature of these two kinds of forces. Aristotle had said that they were things altogether disparate. If so, there can be no proportion between them. Yet the analogy observed in the experiments above mentioned of Galileo, shewed that impulse could be gradually augmented, till it exceed any pressure. This indicates sameness in kind, according to Euclid himself. A curious experiment of Galileo's, in which the impulse of a vein of water was set in equilibrio with a weight, seemed not only to establish this identity beyond a doubt, but even to shew the origin of pressure itself. The weight in one scale is sustained as long as the stream of water continues to strike the other scale. In this experiment, therefore, pressure is equivalent to continual impulse. But *continual* impulse is not conceivable: we must consider the impulse of the stream as the *successive* impulse of the different particles of water, at intervals which are altogether indistinguishable.

From these considerations were deduced two very momentous doctrines: 1. That pressure is nothing but repeated impulse; 2. That although pressure and impulse are the same in kind, they are incomparable in magnitude. The impulse is equal to the weight of a column of water, whose length is the height necessary for communicating the velocity. Now this is incessant; and the weight is sustained during any the smallest moment of time, by the impulse, not of the whole column, but of the insensible portion of it which is then making its stroke. Impulse, therefore, is infinitely greater than pressure.

3
[illegible] the only cause of motion.

These abstruse speculations have a charm for certain ingenious speculative minds; and when indulged, will lead them very far. Accordingly, it was not long before some of the most ingenious philosophers of Europe taught that impulse was the sole origin of pressure.

Impulsion.

There is but one moving power (said they) in mechanical nature: This is impulse.—*Nihil movetur* (says Euler) *nisi a contiguo et moto.* Moreover, having been long and familiarly conversant with the actions of animals, and the actions of moving bodies, and conceiving, with sufficient distinctness, that impenetrable bodies cannot move without moving those with which they are surrounded and in contact, they imagined that they fully understood how all this displacement of bodies is carried on; and therefore they maintained, that any motion is fully explained when it is shewn to be a case of impulsion. But they saw many cases of motion where this impulsion could not be exhibited to the senses. Thus, the fall of heavy bodies, the mutual approach or recess of magnetic and electric bodies, exhibited no such operation. But even here their experience helped them to an explanation. Air is an invisible substance, and its very existence was for a long time known to us only by means of its impulse. As we see that pressures are generated by the impulse of water and of air, may there not be fluids still more subtle than air, by whose invisible impulse bodies are made to fall, and magnets are made to approach or avoid each other? The impossibility of this cannot be demonstrated, and the laws of impulse had not as yet been so far investigated as to shew that they were incompatible with those productions of motion. It was therefore an open field for discussion; and the philosophers, without farther hesitation, adopted, as a first truth, that ALL MOTION WHATEVER IS PRODUCED BY IMPULSION. The business of the philosopher, therefore (say they), is to investigate what combination of invisible impulsions is competent to the production of any observed motion; such as the fall of a heavy body, the elliptical motion of a planet, or the polarity of a magnetic needle. The curious disposition of iron-filings round a magnet encouraged this kind of speculation: It looks so like a stream of fluid; but it is a number of quiescent fragments of iron. This does not hinder us from *supposing* such a stream, not of iron-filings, but of a magnetic fluid, which will arrange (say the atomists) those fragments, just as we see the flote-grass in a brook arranged by a stream of water. Fluids, therefore moving in streams, vortices, and a thousand different ways, have been supposed, in order to *explain*, that is, to bring under a general known law of mechanical Nature, all those cases of the production of motion where impulsion is not observed by the senses.

As we have gradually become better acquainted with the laws of the production of motion by impulsion, we have been able to explode many of those proffered explanations, by shewing that the genuine results of the supposed invisible motions, that is, the impulsions which they would produce, are very unlike the motions which we attempt to explain. It has been shewn, that the vortices supposed by Des Cartes, or by Leibnitz, or by Huyghens, cannot exist; and they have been given up. But it is answered to all those demonstrations of futility, that still the axiom remains. Motion is produced only by impulse; but we have not yet discovered all the possibilities of impulsion; and we must not despair of discovering that precise set of invisible motions, and consequent impulsions, of which the phenomenon before us is the necessary result.

4
The application of this principle is hazardous.

But this is by no means sufficient authority for deserting the rule of philosophizing, so prudently and judiciously recommended by Sir Isaac Newton; namely, not to admit as the cause of a phenomenon any thing that is not *seen* to operate in its production. The prudence of this restriction is evident; and it has also been sufficiently shewn (PHILOSOPHY, *Encycl.* n° 48 &c.), that true philosophical explanation, or extension of knowledge, is unattainable, if this rule be not strictly adhered to. We therefore require a cogent reason for a practice that opens the door to every absurdity, and that cannot give us the knowledge which we are in quest of. What, then, is the reason that always induces philosophers to have recourse to impulsion for the explanation of a phenomenon, and to rest satisfied in every case where it can be clearly proved that the phenomenon is really a case of impulsion? We say that we inquire into the reason why a body falls, and that we will be satisfied if it can be shewn us that it has received a number of impulsions downward. Do we inquire why a body in motion puts another body in motion by hitting it? And if we do, have we discovered the reason? We believe that none of the philosophers, who have recourse to invisible impelling fluids, ever ask a reason for motion by impulsion. Indeed they should not, otherwise it would cease to be a first principle of explanation. Other philosophers, indeed (namely, such as ask no reason for the weight of a body, but the FIAT of the ALMIGHTY), require an explanation of motion by impulse, and think that, in almost every case, they have found it out.

If the philosophers ask no reason for this production of motion, they must (that it may serve as a principle of explanation) say that impulsiveness is an original property of matter, either contingent or essential. Accordingly, we believe that this, or something like this, has been assumed as a principle by the greater part of mechanicians. It has been assumed, as we have observed in the article DYNAMICS, *Suppl.* that a *moving body* possesses the power of producing motion in another body by hitting it; and they call it the IMPULSIVE FORCE *of moving bodies*—the FORCE INHERENT *in a moving body*. The reader will have observed, in our manner of treating that article, and also in several passages of different articles of the *Encyclopædia*, that we do not consider this assumption as very clearly authorised by observation, or deducible by abstract reasoning, from the first principles of philosophy. There is no branch of natural philosophy on which so many ingenious dissertations have been written; and perhaps there is none that has been more successfully prosecuted: Yet this is the only part of the science of motion that has given rise to a serious dispute; a dispute that has divided, and still divides, the mechanicians of Europe.

Some may think it presumptuous in us, in a Work of this kind, which only aims at collecting and exhibiting in one view the *existing science* of Europe, to pretend to give new doctrines, or to decide a question which has called forth all the powers of a Leibnitz, a Bernoulli, a Jurin, a M'Laurin, &c. But we make no such pretensions; we only hope that, by separating the question from others with which it has, in every instance, been complicated, and by considering it apart, such notions may be formed, in perfect conformity to the principles adopted by all parties, that the mystery, which has gradually gathered like a cloud, may be dispelled,

Impulsion.

pelled, and all cause of difference taken away. We apprehend that this requires no very extensive knowledge, but merely a strict attention to the conceptions which we form of the actions of bodies on each other, and a precision in the use of the terms employed in the discussion.

5 Inquiry into its truth. We trust that our philosophical readers perceive and approve of our anxiety to establish (in the article DYNAMICS, *Suppl.*) the leading principles of mechanical philosophy, from which we are to reason in future on acknowledged FACTS, or LAWS of human thought. It is not so much the question, What is the essence of material Nature, from which all the appearances in the universe proceed? as it is, What do we know of it? how do we come by this knowledge? and what use can we make of it? The tænia knows nothing of the solar system, and man is ignorant of the cause of impulsiveness. Other intelligent creatures may have senses, of which this is the proper object; and others, of a still more exalted rank, may perceive the operations of mind as clearly as we perceive those of matter, while they are equally ignorant with ourselves of the causes which connect the conjoined events in either of those operations. But "known unto GOD, and to HIM alone, are ALL His works!"

6 We learn the existence of matter chiefly by means of touch. To accomplish this purpose, we directed the reader's attention to what passes in his own mind when he thinks on the mechanical phenomena of Nature; on what he calls body; on the perceptions which bring it into his view, and which give him all the notions that he can form of its distinguishing, its characteristic properties. How does he learn that there is matter in a particular place? He has more than one mean of information; and each of these informs him of peculiar qualities of the thing which he calls *matter*. Many appearances suggest to his mind the presence of a body. Show a monkey or a kitten (and even sometimes a human infant) a mirror, and it will instantly grope round it to find a companion. Why does the creature grope about so? It is not contented with the first indication of matter, and nothing will satisfy it but touching or grasping what is behind the mirror. It is by our sense of touch alone that we get the irresistible conviction that matter or body is perceived by us, and it never fails to give us the perception; nay, we have the perception even in some cases where the experienced philosopher thinks himself obliged to doubt of its truth. Some sensations, arising from spasm, cannot be distinguished from the feelings of touch; and the patient insists that something presses on the diseased part, while the physician knows that it is only a nervous affection. Every person will think that a cobweb touches his face when an electrified body is brought near it, and will try to wipe it off with his hand. But the modern philosopher sees good reason for asserting, that in this instance our feeling gives us very inaccurate, if not erroneous, information. He shews, that the fact, of which our feeling truly informs us, is the bending of the small hairs or down which grow on the face, and that these only have been touched; and the followers of Æpinus deny that even this has been demonstrated.

7 The excitement of touch is accompanied by the feeling of exerted pressure. The philosopher adopts this mode of perception as unquestionable, and allows that, and that alone, to be matter, which invariably produces this sensation by contiguity. But engaged in speculations which fix his attention on the external object, he neglects and overlooks the instrument of information, and its manner of producing the effect, just as the astronomer overlooks the telescope, and the union and decussation of the rays of light which form the picture by which he perceives the satellite of Jupiter travel across his disk. The philosopher finds it convenient to generalise the immense variety of touches which he feels from external bodies, and to consider them as the operations of one and the same discriminating quality, a PROPERTY inherent in the external substance BODY; and he gives it a name, by which he can excite the same notion in the minds of his hearers. It is worth while to attend to what has been done in this matter, because it gives much information concerning the first principles of mechanism. An exquisite painting has sometimes such an appearance of prominence, that one is disposed to draw the finger along it, and we expect to feel some roughness, some *obstruction*, something that prevents the finger from going over the place. Perhaps we doubt, and want to be assured. We press a little closer; but feel no obstruction; and we desist. The very first appearance, therefore, which this indicating quality, viewed as the *property* of external matter, has in our conceptions, is that of an obstruction, an obstacle, to the exertion of one of our natural powers. The power exerted on this occasion is familiarly and *distinctively* known by the name of PRESSURE. This is the name of our own exertion, our own action; and, in this instance, and (we think) in this alone, the word is used purely, primitively, and without figure. When we say that a stone presses on the ground, we speak figuratively, as truly as when we say that the candlestick stands, and the snuffers lie, on the table. It is a personification, authorised by the similarity of the effects and appearances. Further, when we speak of our pressure on any thing, with the intention of being precise in our communication, we speak only of what obtains in the touching parts of the finger and the thing pressed, paying no attention to the long train of intermediate exertions of the mind on the nerves, the nerves on the muscular fibre, the fibre on the articulated machine, and the machine on the touching part of the finger. And thus the exertion of the sentient and active being is attributed to the particles of lifeless inactive matter at the extremity of the finger, and these are said to press immediately on the touching parts of the external body. And, lastly, as this our exertion is unquestionably the perceived employment of a faculty in us, which we call *force, power, strength*, distinguishing it from every other faculty by these names; we say (but figuratively), that force or power is exerted at the tips of the fingers, and we call it the FORCE OF PRESSURE.

8 [illegible] By far the greatest part of our actions on external bodies is with the intention of putting them out of their present situations; and we can hardly separate the thought of exerted pressure from the thought of motion produced by it. Therefore, almost at its first appearance in the mind, pressure comes before us as a MOVING POWER. Nay, we apprehend, that the more we speculate, and the more we aim at precision in our conceptions, we shall be the more ready to grant that we have no clear *conception* of any other moving power. No man will contend that he has any conception at all of the power exerted by the mind in moving the body.

It

Impulsion.

It is of importance to reflect on the manner in which this notion is extended to all other productions of motion. We think that this will shew, that in every case we suppose pressure to be exerted.

9 Examination of the instances of this perception.

The philosopher proceeds in his speculations, and observes, that one man can press on another, and can push him out of his place, in the same way as he removes any other body; and he cannot observe any difference in his own exertions and sensations in the two cases. But the man who is pushed has the same feelings of touch and pressure. By withdrawing from the pressure, he also withdraws from the sensation; by withstanding or resisting it, he feels the pressure of the other man; and what he feels is the same with what he feels when he presses on the other person, or on any piece of matter. The same sensations of touch are excited. He attributes them to the pressure of the other person. Therefore he attributes the same sensations to the counter-pressure of any other body that excites them. Farther, he can resist to such a degree, that he is not pushed from his place. In this case, the greatest pressure is exerted, and is felt by both. Each feels that the more he resists, the greater is the mutual pressure. And each feels that, unless he *not only do not resist, but also withdraw himself* from the pressure of the other, he will be pressed, and the other will feel counter-pressure, the same in kind with what is produced by his resistance, though less in degree.

10 They are generally figurative.

All these things are distinctly and invariably felt; but they require attention, in order to be subjects of recollection and after-consideration. From this, and no other source, are derived all our notions of corporeal pressure, of counter pressure, of action, re-action, of *resistance*, and of *inactivity* or *inertia*. Our notions of moving power, of the mobility of matter, and of the necessity of this power to produce motion in matter, have the same origin. Our notions also of the resistance of inanimate matter, indicated by the expenditure of actual pressure, are formed from the same premises: the counter-pressure, or what at least produces the same feelings in the person who is the mover, is considered as the property of dead matter; because we feel, that if *we* do not exert real force, we are displaced by the same pressure that would displace a lifeless body of the same bulk.

11 We observe many pressures.

These direct inferences are confirmed as we extend our acquaintance with things around us. We can exert our force in bending a spring, and we feel its counter-pressure, precisely similar to that of another man. We feel that we must continue this pressure, in order to keep it bent; and that as we withdraw our pressure, the spring follows our hand, still producing similar feelings in our organs of touch, and requiring similar exertions of our strength to keep it in any state of tension. These phenomena are interpreted as indications of pressures actually exerted by the spring, and quite different from what we should feel from its mere resistance to being moved. This action resembles our own exertion in every particular; it produces all the effects of pressure; it will squeeze in the soft flexible parts of our body with which we act on it; it will compress any soft body, just as we do ourselves; it will put bodies in motion. Farther, we can set the action of one spring in opposition to that of another, and observe that each is bent by bending the other; and we see that their touching parts exert pressure, for they will compress any soft body placed between them.

Thus, then, in all those cases, we have the same notion of the power immediately exerted between the two bodies, animated or inanimated. It is always pressure. If indeed we begin to speculate about the *modus operandi* in any one of these instances, we find that we must stop short. How our pressure excites the feeling of pressure in the other person, or how it produces motion, eludes even conjecture—So it is—Nay, how our intention and volition causes our limb to exert this pressure, or how the springiness of a spring produces similar effects, remains equally hid from our ken. Unwearied study has greatly advanced our knowledge of these subjects in one respect. It has pointed out to us a train of operations, which go on in our animal frame before the ostensible pressure is produced: we have discovered something of their kind, and of the order in which they proceed; we have gone farther, and have discovered, in some of the pressures exerted by lifeless matter, similar trains of intervening operations. In the case of a spring, we have discovered that there is a certain combination of the properties of all its parts necessary for the visible exertion. But what is the principle which thus makes them co-operate, we cannot tell, any more than in our own exertions of pressure. Such being the origin of our notions on these subjects, it is no wonder that all our language is also derived from it. Force, power, pressure, action, re-action, resistance, impulsion, are, without any exception, words immediately expressive of our own exertions, and applied metaphorically to the phenomena of matter and motion.

Lastly, when we see a body in motion displace another body by hitting it, and endeavour to form a notion of the way in which this motion is immediately produced, fixing our attention on what passes in the very instant of the change, we find ourselves still obliged to suppose the thing we call pressure. We can have no other conception of it; and there is no violence in this act of the imagination. For we know, that if we are jostled from our place, and forcibly driven against another person, we put that person in motion without any intention or action of our own; and we experience, in doing this, that the very same feelings of touch and pressure are excited as in the instances of the same motions produced by exerted pression. We also see, that when a body strikes another, and puts it in motion, it makes an impression or dimple in it if soft, or breaks it if brittle; and in short, produces every effect of pressure. A ball of soft clay makes a dimple in the ball of soft clay which it displaces, and is dimpled by it. Springy bodies compress each other in their collisions, and resile from each other. In short, in every case of this class, mutual pressure, indicated by all its ordinary effects, appears to be the intermedium by which the changes of motion are immediately produced; and the previous motion of the striking body seems to be only the method of producing this pressure.

From this copious induction of particulars, and careful attention to the circumstances of each, we think it plain, that pressure is the only clear notion that a mind, not familiar with scrupulous discussion, forms of moving power; and therefore that it is very singular to think of excluding it from the list, and saying that impulsion 12 Pressure is the only distinct notion of a moving power.

Impulsion. pulsion is the only power in nature, and the source of all pressure.

It may perhaps be said, that the mutual immediate action to which the vulgar, and many philosophers, have erroneously given the metaphorical name pressure is, indeed, the real cause of motion or change of motion; but still it is now properly called impulsion, because it is occasioned only by the previous motion of the impelling body. We conceive clearly, (they may say) how this previous motion produces the impulsion. Since matter is impenetrable, we see clearly that a solid body, or a solid particle, cannot proceed without displacing the bodies with which it comes into contact; we have notions of this as clear as those of geometry; whereas, how pressure is produced, is inconceivable by us. If we press a ball ever so strongly against another, and remove the obstacle which prevented its motion, it will not move an inch, unless we *continue* to follow it, and press it forward; but we see a moving body produce compression, bend springs, make pits in soft bodies, and produce all the effects of real animal pressure. Impulse, therefore, is the true cause of motion, and the solicitation of gravity is nothing but the repeated impulse of an invisible fluid.

But, in the first place, let it be observed, that both parties profess to *explain* the phenomena of mechanical nature, that is, to make them easier conceived by the mind. Now it may be granted, that could we have any previous conviction of a fluid continually flowing toward the centre of the earth, we could have some notion of the production of a downward motion of bodies, but not more explanation than we have without it, because impulsiveness is as little understood by us as pressure.

13 Many pressures are inexplicable by impulsion.

But there are thousands of instances of moving forces where we cannot conceive how they can be produced by the impulse of a body already in motion. There appear to be many moving powers in nature, independent of, and inexplicable by, any previous motion; these may be brought into action, or occasions may be afforded for their action, in a variety of ways. The mere will of an animal brings some of them into action in the internal procedure of muscular motion; mere vicinity brings into action powers which are almost irresistible, and which produce most violent motions. Thus a little aquafortis poured on powdered chalk contained in a bombshell, will burst it, throwing the fragments to a great distance. A spark of fire brings them into action in a mass of gunpowder, or other combustibles. And here it deserves remark, that the greater the mass is to which the spark is applied, the more violent is the motion produced. It would be just the contrary, if the motion were produced by impulse. For in all cases of impulsion, the velocity is inversely proportional to the matter that is moved. When a spring is bent, and the two ends are kept together by a thread, a pressure is excited, which continues to act as long as the thread remains entire. What contrivance of impelling fluid will *explain* this, or give us any conception of the total cessation of this pressure, when the thread is broken, and the spring regains its quiescent form?

14 All pressures do not produce a sensible motion.

We can explain, in a most intelligible manner, why the hardest pressure produces no sensible motion in the case referred to above. We can conceive, with sufficient distinctness, a tube filled with steel wires, coiled up like cork screws, and compressed together into $\frac{1}{10}$th of their natural length. A tube of 10 inches long will contain 100 of them. While in this state, compressed by a plug, we can suppose each of the springs to be tied with a thread. Suppose now that the thread of the spring next the piston is burnt or cut; it will press on the piston, and force it out, accelerating its motion till it has advanced one inch; after this, the piston will proceed with a uniform motion. It is plain, that the velocity will be moderate, perhaps hardly sensible, because the pressure acted on it during a very short time. But if two springs have been set at liberty at the same instant, the pressure on the piston will be continued through a space of two inches, and the final velocity will be greater, because the same (not a double) pressure will be exerted through a double space. Unbending four springs at once, will give the piston a double velocity (See Dynamics, *Suppl.* n° 95). Now the effect of the motion of the second spring is to keep the pressure of the first in action during a longer time, by following it, and keeping it in a state of compression. There is nothing supposed of this kind in the case of strong pressure alluded to; and therefore no motion is produced when the obstacle is removed, except what the insensible compression produces by accelerating the body along an insensible space. If all the 100 springs are disengaged at once, the piston will be accelerated through 100 inches, and will acquire ten times the velocity that one spring can communicate (*N. B.* The force expended in moving the springs themselves is not considered here).

It is in this way only that the previous motion of the impelling body acts in producing a considerable motion. The whole process will be minutely considered by and bye.

15 Impulsion is not more clearly conceived than pressure.

We may now ask, how it is so clear a point, that a solid body in motion must displace other bodies? This seems to be the very point in question, Is the affirmative deduced from our notion of solidity? What is our notion of solidity, and whence is it derived? We apprehend, that even this primary notion is derived from pressure. It is by handling a thing, and finding that we cannot put our hand into the place where it is without displacing it, that we know that it is material. All this is indicated to us by the feeling excited by our pressure. We feel this property always as an obstacle; and therefore say, that by this property it resists our pressure. Nay, there are cases where even the philosopher prefers this quality to impulsiveness as a test of matter. To convince another that the jar out of which he has poured the water that filled it is not empty, but full of matter, he dips the mouth of the jar into water, and shows, that although he press it down till the surrounding water is above the bottom of it, the water has hardly gotten half an inch into the jar; there is something there which keeps it out; there is matter in it. He then opens a hole in the bottom of the jar; the water immediately rises on the inside of the jar, and fills it. He says that the pressure of the water has driven the matter out by the hole; and he *confirms* the materiality of what is expelled, by holding a feather above the hole; it is agitated, shewing that the expelled thing has impulsiveness, another property (he says) of matter; what filled the jar was air, and air in motion is wind. The philosopher can exhibit some new cases, where something like impulsiveness appears.

A slender magnet may be set on one end, the south pole, for instance, and will stand in that tottering situation. If a person bring the north pole of a powerful magnet hastily near the upper end, it will be thrown down, just as it may be blown down by a puff of wind; therefore (says the philosopher) there may be appearances of impulsion, and I may imagine that there is impelling matter; but nothing but matter excludes all other matter from its place: this property, therefore, is the surest test of its presence.

Thus we see, that our notion of solidity or impenetrability (a name still indicating an obstacle to pressure), gives us no clearer conception of the productions of motion by impulsion than pressure does; for it is the same, or indicated by the same sensations.

16 Motion does not impel by transfusing inherent force or inherent motion.

The question now seems to be reduced to this—Since the strongest pressure of a quiescent body does not produce motion, or excite that kind of pressure which is the immediate cause of motion, while a body in motion, exciting but a very moderate pressure (as may be seen by the trifling *compression* or dimpling,) produces a very considerable motion, how is the previous motion conducive to this purpose? The answer usually given is this: A body in motion (by whatever cause), perseveres in that motion by the *inherent force*; when it arrives at another body, it cannot proceed, without displacing that body; the nature of the inherent force is such, that none of it is lost, and that a portion of it passes into the other body, and the two bodies instantly proceed with the same quantity of motion that was in the impelling body alone. This is an exact enough narrative of the general fact, but it gives no great *explanation* of it. If the impelling body perseveres in its motion, by means of its inherent force, that force is exerted in performing its office, and can do no more. The impelled body seems as much to possess an inherent force; for the same marks and evidences of pressure on both sides are observed in the collision. If both bodies are soft or compressible, both are dimpled or compressed. We are as much entitled, therefore, to say, that part of the force by which it perseveres at rest, passes into the other body. But the rest, or quiescence of a body, is always the same; yet what passes into the impelling body is different, according to its previous velocity. We can form no conception how the half of the inherent force of the impelling body is expended by every particle, passes through the points of contact, and is distributed among the particles of the impelled body: nay, we cannot conceive this halving, or any other partition of the force. Is it a thing *sui generis*, made up of its parts, which can be detached from each other, as the particles of salt may be, and really are, when a quantity of fresh water is put into contact with a quantity of brine? We have no clear conception of this; and therefore this is no elucidation of the matter, although it may be an exact statement of the visible fact.

17 This involves absurdities.

Let us take the simplest possible case, and suppose only two particles of matter, one of which is at rest, and the other moves up to it at the rate of two feet per second. The event is supposed to be as follows: in the instant of contact, the two particles proceed with half of the former velocity. Now this instant of time, and this precise point of space, in which the contact is made, is not a part of either the time or space before collision, or of those after collision; it is the boundary between both; it is the last instant of the former time, and the first instant of the latter time; it belongs to both, and may be said to be in both. What is the state or condition of the impelling particle in this instant? In virtue of the previous motion, it has the determination, or the force, or the power, to move at the rate of two feet per second; but, in virtue of the motion after collision, it has the determination or power of moving at the rate of one foot per second. In one and the same instant, therefore, it has two determinations, or only one of them, or neither of them. And it may, in like manner, be said of the impelled body, that in that instant, it was both at rest, and moving at the rate of one foot per second. This seems inconceivable or absurd.

18 Impulsiveness is not an intuitive property of matter,

It is not perhaps very clear and demonstrable, nor is it intuitively certain, that the moving body or particle must displace the other at all. All that we know is, that matter is moveable, and that causes of this motion exist in nature. When they have produced this motion, they have performed their task, and the motion is their complete effect. The particle continues in this condition forever, unless it be changed by some cause; but we do not see any thing in this condition that enables us to say what causes are competent to this change and what are not. Is it either intuitive or demonstrable, that the *mere existence* of another particle is not a sufficient or adequate cause? Is it certain that the arrival at another particle is an adequate cause? or can we prove that this will not stop it altogether? The only conclusion that we can draw with any confidence is, that "two particles, or two equal bodies, meeting with equal velocities in opposite directions, will stop." But our only reason for this conclusion is, that we cannot assign an adequate reason why either should prevail. But this form of argument never carries luminous conviction, nor does it even give a decision at all, unless a number of cases can be specified, which include *every possible result*. This can hardly be affirmed in the present case.

19 But an observed fact.

We apprehend, that the next case, in point of simplicity, has still less intuitive or deductive evidence; namely, when bodies meet in opposite directions with equal quantities of motion. It is by no means easy, if it be at all possible, to shew that they must stop. The proof proceeds on some notion of the manner in which the impulsion, exerted on one particle, or on a few of each body, namely, those which come into contact, is distributed among all the particles. A material atom is moved only when a moving force acts on it, and each atom gets a motion precisely commensurate to the force which actuates it. Now, it is so far from being clear, how a force impressed on one particle of a solid body, occasions an equal portion of itself to pass into every particle of that body, and impel it forward in the same direction, that the very authors who assume the present proposition as an elementary truth, claim no small honour for having determined with precision the moving forces that are exerted on each particle, and the circumstances that are necessary for producing an equal progressive motion in each. It was by no means an easy problem to shew, that the motion of the body (estimated by an average taken of the motions of every particle) is precisely that which is announced by this proposition.

Impulsion.

proposition. We must also consider how this investigation is conducted. It is by assuming, that whatever force connects a particle *a* with a particle *b*, or whatever force *a* exerts on *b*, the particle *b* exerts an equal force on *a* in the opposite direction—Surely no logician will say that this is an intuitive truth. The contrary is most distinctly conceivable. It was a *discovery* of the astronomers, that every deflection toward the sun is accompanied by an equal deflection of the sun. It was a *discovery* that a piece of iron attracts a loadstone; and it was a *discovery* (and we dare not yet affirm it to be without exception) that every action of bodies is accompanied by an equal and contrary re-action. But this is by no means a first principle. It is the expression of a most generally observed fact, a sum total of knowledge. When received on this authority, it is fully competent to solve every case of impulsion, independent of all obscure and illogical doctrines of force inherent in moving bodies, of force of inertia, of communication of motion, &c.

The impossibility of conceiving the detachment of part of the *force* inherent in A, and transferring *this* part into B, and the similar impossibility of conceiving the imparting to B some of the *motion* that was in A, should make us reject any proposition involving such conceptions, and refuse its admission as an elementary truth. Much more should we reject a proposition that obliges us to suppose that a particle of matter has two determinations, forces, motions, or call them by any other name, in one and the same instant. One of these necessarily excludes the other. Indeed this was so evident, even to the most eminent partizans of the doctrine of the transfusion of inherent force, and others consequent on it, that they found themselves obliged to deny that there was such a thing in the world as a perfectly hard body, in which the motion must be instantaneously changed into another, differing from it by any sensible quantity. The existence of perfectly hard bodies is positively denied by the celebrated mathematician of Basle, John Bernoulli, in his Dissertation on the Communication of Motion, which contended for the prize given by the Academy of Sciences at Paris 1710. His reason for this rejection is singular, and somewhat amusing. "In the collision of perfectly hard bodies, the *conservatio virium vivarum*, demonstrated by the most eminent mathematician (Mr Leibnitz), to be a law of nature, would be broken without any effect being produced. He does not observe, that it is as completely broken by elastic bodies in the instant of greatest compression. A British philosopher, *nullius addictus jurare in verba magistri*, asked, What will be the case of two encountering atoms of matter? Without calling them hard, we must conceive that they acquire their changes of motion in the instant of mutual contact, and that they acquire them *totally*, being ἄτομοι, indivisible. No answer has been given, or indeed can be given, but what implies the same difficulty. From all that has been said, we must conclude, that this branch of mechanical philosophy is not put, by those philosophers, into the condition of an elementary foundation of clear and demonstrative science; that the transfusion or transference, either of force or motion, is not a thing of which we have a distinct conception; and that it necessarily leads us into very untenable doctrines. Far less does it seem safe for us to confide so much in its clearness and certainty, as to affirm, that impulsion is the sole moving force in mechanical nature, and the source of what we call pressure.

All this difficulty and obscurity has arisen from our arrogant notion that we are competent judges of first *principles*; whereas we must acknowledge, that we can only perceive such as are properly related or accommodated to our intellectual powers: these powers, being specific and peculiar, cannot judge of principles of the first class, but of those only that are *suitably* compounded. We can never know or comprehend any essential property of matter—we can only know the *relative* properties of *such matter as we see*.

20 Therefore to be learned only by observing nature.

Therefore let us quit entirely the barren and trackless fields of abstraction, and rest satisfied with contemplating *what* the Author of Nature has exhibited to our view, and *such* as he has been pleased in his wisdom to exhibit it. We grant that there are no bodies open to our inspection which are perfectly hard, receiving finite changes of motion in an instant. It has not pleased God to put any such within our reach. When God created matter, it was with the purpose of forming a beautiful universe of this matter. He therefore gave it properties which fitted it for this purpose. It is this matter only that he has exposed to the wondering view of man. Thanks to his bounty, he has also given us properties of mind, by which this adaption, when perceived by us, becomes a source of dignified pleasure to the observer. A Newton, to whom "*Jovis omnia plena*," a Daniel Bernoulli, were rapt almost into ecstacy by a single atom, when they observed how its properties, and only such properties, fitted it for making part of a world, which

Unwearied, and from day to day,
Should its CREATOR's power display.

Let the unhappy La Place consider these properties, which ensure the permanency of the solar system through ages of ages, as proofs of fatalism, as qualities essential to matter. But this Gallic torch effaces the bloom of life from the universe, the expression of the Supreme Mind which shines from within; and it spreads over the countenance of Nature the ghastly paleness of universal death. But let us Britons rather follow the example of our illustrious countryman, and solace ourselves with every discovery which tends to quicken our perception of Nature's *animated* charms. Let us listen to the conjectures of him who had already discovered so many, and who endeavoured to remove the veil which concealed the rest.

21 Moving powers are inherent in all matter. Newton's conjecture improved by Boscovich.

Newton, in his maturity of judgment, after having collected much information from his unwearied experiments in magnetism, in chemistry, in optics, &c. said, that "he strongly suspected, that, in the same manner as the bodies of the solar system were connected by gravitation, so the particles of sublunary bodies were connected together, and affected each other, by means of forces which acted at small, and, in many cases, insensible distances; producing the phenomena of cohesion, in all its forms of hardness, elasticity, ductility, softness, fluidity, by which their mechanical actions on each other were modified and regulated." Father Boscovich, one of the first mathematicians of Europe, was the first who gave this conjecture of Newton's ton's the attention that it so highly deserved. Other writers, indeed, such as Keill, Freind, Boerhaave, &c. took occasional notice of it, and even made some use of it in their attempts to explain some complicated phenomena of nature. But they were so careless in their employment of Newton's conjecture, so completely neglected his cautious manner of proceeding, indulged so wantonly in hypothetical assumptions, and reasoned so falsely from them, that they brought his conjecture into discredit. Boscovich, on the contrary, copied Newton with care, and secured his progress as he advanced, by the aid of geometry; establishing a set of uncontrovertible propositions, which must be the inevitable results of the premises adopted by him. He then proceeded to compare these with the phenomena of nature; and he shews that the coincidence is as complete as can be desired. All this is done in his *Theoria Philosophiæ Naturalis*, first published at Vienna in 1759. We have given a very short account of it in the article Boscovich, *Suppl.*; but it hardly goes beyond the enunciation of the general principle, and the indication of its applicability to the purposes intended. His application to the production of motion by the collision of bodies, is peculiarly satisfactory. But as the work is written chiefly with the view of gaining the approbation of persons well instructed in natural philosophy, it can hardly be called an elementary work, or be employed for the instruction of persons entering on the study. We shall attempt to explain this important law of mechanism in a way that will give our readers a distinct notion (and, we apprehend, a just one) of the procedure of Nature in all the cases of impulsion *that we can observe*. We hope to do this, by considering the changes of motion produced by moving bodies in a certain series of familiar cases, where the procedure of nature may be distinctly observed, and where it is uniformly conceived by every spectator; and which will gradually lead the mind to those cases where the procedure is not observed with distinctness; but the similarity to the former case is concluded by so fair analogy, that we imagine no person will controvert it. We shall begin by attending to the manner in which two magnets in motion affect each other's motions; a phenomenon that is familiarly known in the general, although, perhaps, few persons have attended to it minutely.

Plate XXIX. 22 Examination of the mutual actions of magnets.

Let us, therefore, suppose two magnets, A and B (fig. 1.) equal in weight (in the first instance). Let them be made to float on water, by placing them on pieces of cork. Let them be placed with their north poles touching each other. Let A be held fast, and let B be at liberty to move. We know that it will gradually recede from A, with a motion that would continually accelerate, were it not for the resistance of the water. What is the inference drawn from this appearance? Surely this, that either a moving power, inherent in A, repels B, or that B avoids A, by an evasive power inherent in itself. It is immaterial for our purpose which opinion we adopt. Let us say that A repels B. This admits more concise language than the other. If we prevent this motion of B by means of a very slender spring applied to its remote end, we shall observe that the spring is bent back a little, just as if we were pushing away the magnet gently with the finger; and we observe, that the bending of the spring is so much the greater as B is nearer to A. We can judge of the intensity of the force by which B is actuated, by the bending of the spring—This force is equal to the *weight* of any body that will bend the spring to the same degree. This force is analogous, therefore, to the weight, the pressure of gravity, and we may call it a pressure, and measure it by grains weight. Every force that can bend a spring will move a body. This is a well known fact. Therefore it is next to certain, that it is this force which causes B to recede from A; nay, if we compare the motion of B with what *should* result from the action of a force having this very intensity, and varying in the same manner by a change of distance from A, taking in the diminution which the resistance of the water must occasion, we shall find the motions precisely the same. All this can be discovered by Dynamics, n° 95, &c. Therefore we must conclude that this, and no other, is the cause of the recess of B.

If, instead of placing B in contact with A, we place it at a distance from it, and push it toward A with an initial velocity, somewhat less than it would have acquired in that place by its recess from A, we shall find that it will approach A with a motion gradually retarded, till it stop at a small distance from A; and will now recede from it again with an accelerated motion. In short, we shall find that its whole motion to and from A is precisely the same with what results from a similar computation by n° 95. of Dynamics.

The whole of this phenomenon is conceived by every beholder, who has not imbibed some peculiar theory of a stream of impelling fluid, as the indication and effect of a repulsive force exerted by A on B, or of a quality of B, by which it recedes from A.

If now B be held fast, and A be set at liberty, it is observed to be repelled by B, or to recede from B, in the same manner, and with the same force.

Thus, the two magnets appear to affect each other's motions, and are thought, and said, by all to repel each other. The effect appears curious, but excites no farther thought in most minds: it is only the speculatist that begins to suspect that he has not conceived it properly.

Now, let us suppose that B is afloat on the surface of the water, and at rest; and that A is pushed towards it, by a single stroke, causing it to move so moderately that it shall not strike B, but have its motion destroyed by the repulsion before it reaches it; and let us farther suppose, that the initial velocity of A was exactly measured—the fact will be as follows. As soon as A comes within a certain distance of B, its motion begins to be affected; it gradually diminishes, and at length it ceases entirely, and A remains ever after perfectly still. But it is also observed, that in the instant that A slackens its motion, B begins to move; that it gradually accelerates in its motion, and at last acquires the initial velocity of A, with which it proceeds, till the resistance of the water brings it to rest, perhaps at a considerable distance from A. This experiment is very amusing, and the initial velocity of A may be increased in each succeeding trial, till at last it strikes B. Even then the general appearance remains the same: A is brought to rest and remains at rest, neither resiling nor advancing forward; and B moves off with the initial velocity of A. What we wish to be

Impulsion.

be particularly noticed is, that as long as the initial velocity of A is less than a certain quantity (depending on the strength of the magnets), the motion is communicated to B, or, to express it more cautiously, motion is produced in B, without any thing happening that can get the name of impulsion with propriety. In the ordinary conceptions and language of mankind, impulse always supposes actual contact; and impulsion is equivalent to a blow or a stroke. Both of these are indeed metaphorical terms, as well as impulsion. Perhaps the word "to hit," expresses this particular case more purely, and it is perhaps without any figure, and is the appropriate word. We do not speak at present of the conception and language of philosophers, but of persons taking an unconcerned view of things, without any intention of speculating farther about the matter.

Appearances perfectly similar are observed in electrified bodies. If we hang two equal bunches of very light downy feathers by two equal linen threads, so as to hang close by each other like pendulums without touching, and if, after having electrified them so that they repel each other to some distance, we draw one of them, which we shall call A, considerably aside from the perpendicular, and then let it go to swing like a pendulum; we shall observe, that instead of accelerating till it reach the lowest point of its vibration, its motion will be retarded; it will stop entirely when its thread is perpendicular, and will remain at rest. In the mean time, the other bunch B will acquire motion, which will gradually increase till it equal the motion of A in its maximum state; and with this it would proceed for ever, were it not rising like a pendulum in the arch of a circle. The general fact is the same as in the case of the magnets. The moving body is brought to rest, in which state it continues, and the quiescent body moves off with an ultimate velocity, equal to the initial velocity of the other; and all this happens without contact or impulsion, but is produced by the mutual repulsion of the electrified bodies.

If this general fact be compared with what happens in the collision of two billiard balls, it will be found perfectly similar in every respect, but that of the contact and the impulsion, properly so called. The impelling ball is brought to rest, and remains at rest; and the impelled ball moves off with the velocity of the impelling ball.

This being the case, it is plain that we may derive some information from the motion of the magnets, that must greatly assist us in our conceptions of what passes in the rapid, if not instantaneous, production of motion in a billiard ball, by hitting it with another. In the case of the magnets, we perceive, and can discriminate, a progressive train of changes, which terminate in a final change, perfectly similar to the change in the impulsion of the billiard ball. This will justify a very minute attention to, and statement of, all the circumstances.

23 First case. A moving toward B at rest.

Let us attend to the process of this operation, and the production of motion in the magnet originally at rest, and the abolition of it in the one originally in motion; and let us reflect on what passes in our minds when we try to explain it to ourselves. The trials mentioned at first, when one magnet was held fast, shew us that each magnet repels or avoids the other, and that this action is found to be equal on both sides, producing equal compression of the spring employed for ascertaining the intensity of this repulsion when the distances are the same. This is the fact. It is no less a fact, that equal moving forces, such as equal pressures must be supposed to be, produce equal changes of motion in their own direction. Therefore, as soon as A comes to such a distance from B that the mutual action takes place, both magnets are affected, and equally affected; that is, equal changes of motion are produced on each, but in opposite directions. The motion of A is diminished, perhaps $\frac{1}{100}$th part, in $\frac{1}{10}$th of a second, and (let it be carefully remembered) while A passes over a certain space, suppose the 10th of an inch. During this small portion of time, B acquires as much motion as A loses. This is not the motion lost by A. This is inconceivable; for motion is not a thing, but a condition. But it is an *equal degree* of motion. B has passed over a small space during this time, perhaps the 50th part of an inch, with an almost imperceptible motion, that is gradually accelerated from nothing. Since A is moving faster than B, it must still gain upon it; and therefore the mutual repulsion will increase; and in the next 10th of a second this force will take another and greater portion of A's original velocity from it, and will add a greater velocity to that already acquired by B. And thus, in every succeeding minute portion of time, the motion of A will be more and more diminished, and that of B as much increased, by the equal, though continually increasing, simultaneous repulsions acting in opposite directions. It is evident, that it is possible that the velocity of A may be so much diminished, and that of B so much increased, that the remaining velocity of A shall be just equal to the acquired velocity of B. Till this happens, the distances of the magnets have been continually diminishing; for A has been moving faster than B, and gaining on it. If the operation of the mutual repulsions could be stopped at this instant, both magnets would move forward for ever with equal velocities.

24 They acquire a common velocity

It is of particular importance to know what this common velocity is. This is determined by our previous knowledge, that the magnets repel or avoid each other with equal forces. These forces may vary by a variation of distance; but the force acting on A is always equal and opposite to the force acting at the same time on B. This is the uncontroverted fact (the authority for which shall soon be considered). These equal forces must therefore produce equal and opposite changes of motion. The motion acquired by B is equal to that lost by A. But the magnets being supposed equal, and moving with equal velocities, they have equal quantities of motion. Therefore the motion acquired by B, or that lost by A, is equal to what remains in A; that is, A has lost half of its motion, and therefore half of its velocity; or the common velocity is half of the primitive velocity of A.

It was for the sake of a somewhat easier discussion that we supposed the magnets to be of equal weights. But it is almost equally easy to ascertain what this common velocity will be in any other proportion of the quantities of matter in A and B. It is a matter of unexcepted experience, that whatever be the weight or strength of two magnets, their actions on each other are always equal. Therefore the simultaneous force must always produce.

produce equal changes of motion in the two bodies. But the change of motion is expreſſed by the product of the quantity of matter and the change of velocity. Therefore let A and B repreſent the quantities of matter in the magnets; and let a be the primitive velocity of A, and x the velocity which obtains when both are moving with one velocity. The velocity loſt by A is $a - x$. Therefore we muſt have $Bx = A \times \overline{a - x}$, $= Aa - Ax$; and $Aa = Ax + Bx$, $= \overline{A + B} \times x$, and $x = \frac{Aa}{A+B}$. *The common velocity is therefore obtained by dividing the primitive quantity of motion by the ſum of the quantities of matter.*

25 Namely. $x = \frac{A \times a}{A+B}$.

This may be conceived more compendiouſly in another way. Since B acquires as much motion as A loſes, the whole quantity of motion is the ſame as before: Therefore the common velocity muſt be had by dividing this quantity of motion by the whole quantity of matter. But we wiſhed to make the reader keep his attention fixed on the ſteps of procedure, and ſee the connection of each with the cauſes.

We ſhall find that this period of the whole proceſs, namely, the moment when both bodies have acquired a common velocity, and the preciſe magnitude of this velocity, are points of peculiar importance in the doctrine of impulſion; indeed they almoſt comprehend the whole of it.

26 But this does not continue, and the magnets ſeparate.

But this is a ſtate that cannot continue for a moment in the example before us. The repulſive or evaſive forces are ſtill acting on both magnets, and ſtill diminiſh the motion of A, and equally increaſe the motion of B. Therefore the velocity of A, in the very next moment, muſt be leſs than that of B; and B has, during this moment, gained on A, or has removed farther from it. This continues; A is ſtill retarded, and B is accelerated; and therefore gains more and more upon A, or ſeparates farther and farther from it. This muſt continue as long as the mutual repulſions are ſuppoſed to act. If we ſuppoſe that the *ſenſible* action of theſe forces is limited to ſome determinate diſtance, the mutual action will ceaſe when B has got to that diſtance before A. We may call it *the inactive diſtance.* After this, A and B will proceed with the velocities which they have at that inſtant. Let us inquire into theſe final velocities; and thus complete our acquaintance with the proceſs.

27 The common velocity is attained at the inſtant of neareſt approach.

We ſee (and it is important) that the magnets are in their ſtate of greateſt proximity at the inſtant of their moving with a common velocity, and that after this they gradually ſeparate, till they are again at their inactive diſtance. During this ſeparation they attain diſtances from each other equal to what they had during the period of their mutual approach. At theſe diſtances the repulſions are the ſame as before, and act in the ſame direction. Therefore, in each moment of ſeparation, and at each diſtance, A ſuſtains the ſame diminution, and B gets the ſame augmentation of its motion, as when they were at the ſame diſtance in the period of their mutual approach. The ſums total, therefore, of theſe equal augmentations and diminutions muſt be equal to the augmentation and diminution during the approach. Therefore the whole diminution of A's motion muſt be double of the diminution ſuſtained during the approach; and the whole augmentation of B's motion muſt, in like manner, be double of that acquired during the approach of A. Hence we eaſily ſee, that when the magnets are ſuppoſed equal, A muſt be brought to reſt; for in the period of approach it had loſt half of its velocity. It muſt now have loſt the whole. For ſimilar reaſons B muſt finally acquire the primitive velocity of A; for in the inſtant of greateſt proximity, it had acquired the half of it.

28 Repulſion is a cauſe adequate to the obſerved effect.

Thus we ſee, that the equal mutual repulſions are preciſely adequate to the production of the changes of motion that are really obſerved; and muſt therefore be admitted as the immediate cauſes of theſe changes.

29 Effect when the magnets are unequal.

It is equally eaſy to aſcertain the final velocities when the magnets are of unequal ſizes; for the equality of their mutual repulſions is not affected by any inequality of their magnitudes. Their ſeparations, and the changes of motion during theſe ſeparations, will be the ſame with their approaches and the correſponding changes of motion; and the whole change on each will be double of the change ſuſtained at the inſtant of greateſt proximity and common velocity. Hence we learn, that the final velocity of B is $2x$, or $\frac{2Aa}{A+B}$; and the final velocity of A is $\frac{\overline{A-B} \times a}{A+B}$. For the primitive velocity of A being a, and the common velocity, in the inſtant of neareſt approach, being $\frac{Aa}{A+B}$ the loſs of velocity is $a - \frac{Aa}{A+B}$, $= \frac{Aa + Ba - Aa}{A+B}$, $= \frac{Ba}{A+B}$. Therefore the final loſs of velocity is $\frac{2Ba}{A+B}$, and the remaining final velocity is $a - \frac{2Ba}{A+B}$, $= \frac{Aa + Ba - 2Ba}{A+B}$, $= \frac{\overline{A-B} \times a}{A+B}$.

30 II. Caſe. Both magnets in motion in one direction.

Let us, in the next place, ſee what will be the reſult when both of the magnets are in motion at the beginning of their mutual action. And, firſt, let both move in one direction. Let A, moving with the velocity a, overtake B, moving in the ſame direction with the velocity b, leſs than a. Moreover, let the velocities a and b be ſuch, that their difference $a - b$ is ſomewhat leſs than the ſum of the velocities α and β, which the mutual repulſions of the magnets would generate in them, if the magnets were placed in contact, and allowed to recede from each other till they get beyond their acting diſtance.

Theſe things being premiſed, let the magnets be ſet in motion in the ſame direction with the above-mentioned velocities a and b. The magnet A muſt gain on B, and at laſt come ſo near it, that the mutual repulſions begin to act on both. It is plain, that the motion of A will be diminiſhed, and that of B increaſed, by equal quantities, during every minute portion of the time of their mutual action. It is alſo evident, that the velocity of A may be ſo much diminiſhed, and that of B ſo much increaſed, that they ſhall be rendered equal. Alſo this will happen before the magnets touch one another; becauſe the original difference of their quantities of motion has been ſuppoſed leſs than the motion which the repulſive forces are able to generate or extinguiſh, by acting on them through the whole diſtance which gives occaſion to their action. Therefore

Impulſion. fore the difference of the velocities is leſs than the ſum of the velocity α, which the mutual repulſion can take from A, and the velocity β, which it can give at the ſame time to B. The magnets will gradually approach, and the mutual repulſions, and conſequent diminution of A's, and augmentation of B's motion, will gradually increaſe, till the ſum of α and β is juſt equal to the difference of a and b; that is, till the bodies are moving with one velocity. If the mutual repulſions were annihilated at this inſtant, the bodies would move forward with this common velocity. What this is we determine with great facility, as we did in the former caſe: Becauſe the repulſions produce equal and oppoſite changes of motion in the magnets, as much is taken from $A \times a$ as is added to $B \times b$; and the ſum of $A \times a$, and $B \times b$, is equal to the ſum of $A \times x$ and $B \times x$, or $\overline{A+B} \times x = A \times a + B \times b$, and $x = \frac{Aa + Bb}{A + B}$. Therefore *the common velocity is had by dividing the ſum of the primitive quantities of motion by the ſum of the quantities of matter.*

31 Common velocity $= \frac{Aa + Bb}{A + B}$, but the magnets ſeparate, and the change is doubled in each.

But the repulſive forces continue to act as in the former caſe. The motion of A is ſtill more diminiſhed, and that of B augmented: Therefore the velocity of B muſt now exceed the velocity of A, and the magnets muſt ſeparate. Reaſoning in the ſame way as in the former caſe, it is evident that the mutual action does not ceaſe till the magnets have ſeparated to their inactive diſtance from each other, and that the whole change of motion in each is double of the change that it had ſuſtained when they were in their greateſt proximity, and moving with a common velocity. Theſe conſiderations enable us to aſcertain the final ſtate of each. The common velocity is $\frac{Aa + Ab}{A + B}$. Therefore the change made on the velocity of A, at the inſtant of greateſt proximity, is $a - \frac{Aa + Bb}{A + B}$, or $= -\frac{B \times \overline{a - b}}{A + B}$, and the final velocity of A is $a - \frac{2B \times \overline{a - b}}{A + B}$. In like manner, the change produced on the velocity of B is $= \frac{Aa + Bb}{A + B} - b$, or $= + \frac{A \times \overline{a - b}}{A + B}$, and the final velocity of B is $b + \frac{2A \times \overline{a -}}{A + B}$. We may alſo obtain the final velocity of each, by taking its initial velocity from twice the common velocity.

If, in this example of two magnets in motion, we ſuppoſe them of equal weight, we ſhall find that they will finally proceed with exchanged velocities. For when $A = B$, it is plain that $a - \frac{2B \times \overline{a - b}}{A + B}$ is $= a - 1 \times \overline{a - b}, = a - a + b, = b$: and $b + \frac{2A \times \overline{a - b}}{A + B}$ is $= b + 1 \times \overline{a - b}, = b + a - b, = a$. This caſe is eaſily ſubjected to experiment, and will be found fully confirmed, if we take into account the retardations occaſioned by the reſiſtance of the water to the motions.

Let us, in the next place, ſuppoſe the magnets to be moving in oppoſite directions with the velocities a and b; and (in order that the magnets may not ſtrike each other) let the ſum of a and b be leſs than the ſum of α and β, which the repulſions of the magnets would produce by repelling them from contact to their inactive diſtance. Impulſion. 32 Magnets moving in oppoſite directions.

As ſoon as the magnets arrive at their acting diſtance, their mutual and equal repulſions immediately begin to diminiſh both of their motions; and in any minute portion of the period of their approach, equal quantities of motion are taken from each. It is evident, that if the primitive quantities of motion have been equal; that is, if A and B have been moving with velocities reciprocally proportional to their quantities of matter, then, when the motion of one of them has been annihilated by their mutual repulſion, the motion of the other will be deſtroyed at the ſame time, and both will be brought to reſt. Were the repulſions annihilated at this inſtant, they would remain at reſt. But becauſe thoſe forces continue their actions, the magnets will ſeparate again, regaining, at every diſtance, the velocity which they had, when at that diſtance, during their mutual approach; and when they have reached their inactive diſtance, they will have regained each its original momentum and velocity, but in the oppoſite direction. This needs no farther comment; but muſt be kept in mind, becauſe this caſe has a preciſe counterpart in the colliſion of ſolid bodies, meeting each other in oppoſite directions with equal momenta. But if the momentum of one exceed that of the other, thus, if $A \times a$ be greater than $B \times b$, then, when the magnet B is brought to reſt, A has ſtill a momentum remaining equal to $Aa - Bb$. Having therefore a certain velocity, while B has none, it muſt approach ſtill nearer to B, and a ſtill greater repulſion will be exerted on B than if A had alſo been brought to reſt, but ſtill repelling B. Since B is now acquiring motion in the direction oppoſite to its former motion, and A is ſtill loſing motion, a time muſt come when the motion of A is ſo much diminiſhed, and that of B ſo much augmented, that they are moving with a common velocity in the direction of A's primitive motion. The reaſoning employed in the foregoing examples ſhews us, that, in the preſent caſe alſo, this ſtate of common velocity is alſo the ſtate of the greateſt proximity, and that the magnets ſeparate again, till they attain their diſtance of inaction, and that the total change in each is double of what it was in their ſtate of greateſt proximity.

To find this common velocity, recollect, that when the momentum of B was extinguiſhed, that of A was ſtill $= Aa - Bb$. From what has been already ſaid on the other caſes, we know that when the common velocity obtains, the whole momenta are ſtill equal to $Aa - Bb$. Therefore the common velocity x muſt be $= \frac{Aa - Bb}{A + B}$. 33 Common velocity $= \frac{Aa - Bb}{A + B}$; but the change is doubled by the ſubſequent ſeparation.

The velocity left by A muſt therefore be $a - \frac{Aa - Bb}{A + B}, = \frac{B \times \overline{a + b}}{A + B}$, and the final velocity will be $a - \frac{2B \times \overline{a + b}}{A + B}$. The final motion of A will be in the ſame direction as at firſt, if a be greater than

Impulsion.

$\frac{2\,B\,\overline{a+b}}{A+B}$, otherwise it will be in the opposite direction.

In like manner, the change of velocity in B is $b + \frac{A\,a - B\,b}{A+B}$, because the former velocity b is destroyed, and the new velocity is $\frac{A\,a - B\,b}{A+B}$ in the opposite direction. This is $= \frac{A \times \overline{a+b}}{A+B}$, and the final velocity of B is $= b - \frac{2\,A \times \overline{a+b}}{A+B}$.

34
The changes of motion in the magnets are similar to those in the collision of bodies.

Thus we have shewn, in the case of magnets acting on each other by repulsive forces, or actuated by forces equivalent to repulsive forces, how changes of motion are produced, which have a great resemblance to those which are seen in the collision of solid bodies. The motions which obtain in the instant of greatest proximity are precisely similar to what *are observed* in the collision of unelastic bodies. Their common velocity after collision is always $= \frac{A\,a + B\,b}{A+B}$, or $= \frac{A\,a - B\,b}{A+B}$, according as the bodies were moving in the same or in opposite directions. The final motions of the magnets are also precisely similar to what *are observed* in the collision of perfectly elastic bodies. We took the instance of magnets, because the object is familiar; but we can substitute, in imagination, an abstract repulsive force in place of magnetism, and we can assign it any intensity, and any law and limits of action we please. We can imagine it so powerful, that although its action be limited to a very small, and even insensible distance, it shall always reduce the meeting bodies to a common velocity before they come into actual contact; and therefore without any real impulsion, as impulsion is commonly conceived.

There are some farther general observations that may be made on those motions which are of importance.

35
These changes are proportional to the relative motion.

1. We see that the changes of motion, and consequently the actions, are dependent on the relative motions only, whatever the absolute motions may be: For changes are always as $a - b$ when the bodies are moving in one direction, and as $a + b$ when they are moving in opposite directions. Now $a \mp b$ is the relative motion.

36
And reciprocally as the quantities of matter.

2. The change of velocity in each of the two bodies is inversely as its quantity of matter, or is proportional to the quantity of matter in the other body. The changes in A and B are $\frac{B \times \overline{a \mp b}}{A+B}$ and $\frac{A \times \overline{a \mp b}}{A+B}$. The changing forces being equal on both sides, produce equal changes in the quantities of motion; and therefore produce changes of velocity that are inversely as the quantities of matter.

37
CONSERVATIO MOMENTORUM.

3. During the whole process, the sum of the momenta, or quantities of motion, remains the same, if the bodies are moving in one direction: if they are moving in opposite directions, it is the difference of momenta that remains the same; for in every instant of the process equal changes of momentum are made in opposite directions. When the motions are in the same direction, as much is taken from the one as is added to the other; and therefore the *sum* remains unchanged. When the motions are in opposite directions, equal quantities are taken from both; and therefore the *difference* remains unchanged. This is called the CONSERVATIO MOMENTORUM; and it is usually enunciated by saying, that the quantity of motion, estimated in one direction, is not changed by the equal and opposite actions of the bodies. This is a particular case of a general law affirmed by Des Cartes, that the quantity of motion in the universe remains always the same when estimated in *any* one direction.

38
CONSERVATIO VIRIUM VIVARUM.

4. When the whole process is completed, the sum of the products made by multiplying each body by the square of its final velocity, is equal to the sum of the products made by multiplying each body into the square of its initial velocity. For when the process is completed, the two bodies are at the same distance from each other as when the mutual action began. Therefore, during the process, each body has passed over an equal space, and in every similar point it has been acted on by an equal force (although this force be different in different points of this space). Therefore, in every instant, the simultaneous products of the quantity of matter by the momentary variation of the square of the velocity are equal on both sides; and therefore the products of the quantity of matter by the whole change of the square of the velocity are also equal on both sides. See DYNAMICS, *Suppl.* n° 95. and 110. where $v\dot{v} = \frac{f\dot{s}}{m}$; and therefore $m\,v\,\dot{v} = f\dot{s}$, and $m \times V^2 - v^2$, or $n \times v^2 - V^2 = \int f\dot{s}$. Now, since these changes are in opposite directions, as much is added to one product as is taken from the other, and the sum of the products of the quantities of matter by the squares of the final velocities, is equal to the sum of the products of the same quantities of matter by the squares of the initial velocities.

These two theorems are not principles, but general facts.

This is a particular case of the famous CONSERVATIO VIRIUM VIVARUM, claimed as a mighty discovery by the partizans of Leibnitz, and ascribed to him; but he has no claim whatever to the discovery. It was communicated to the Royal Society of London in 1668 by Huyghens, as one of the general laws of impulsion, obtaining in what he calls *hard bodies*. Several of the Leibnitzian school, indeed, extended it farther than Huyghens had done; some of them indeed very lately. The observation of this general law was soon applied to many excellent purposes in the solution of very intricate problems; because it often saved the trouble of tracing the intermediate steps of a complicated process. Assured that these products were invariable, the mathematician found it an easy matter to state what conditions of the question insured this equality of products; and thus the problem was solved. In this manner Daniel Bernoulli gives most elegant solutions of some, otherwise almost intractable, problems in Hydraulics. For such reasons, as a mighty aid in mechanical investigation, the discovery of Huyghens is extremely valuable. Its merit in this respect is perfectly similar (though perhaps somewhat greater) to Des Cartes's observation of the *conservatio momentorum*. It is also like the observation or discovery of Maupertuis, which he calls *the law of smallest action* (indeed it is the same under a different

Impulsion.

ferent aspect), or La Grange's *law of virtual velocities*, or D'Alembert's *law of equilibrium of action*;—all of these are general facts, laws by which the changes of motion are *observed* to proceed. But their authors have vaunted them as principles, as causes, from which to conclude effects; whereas they are really inductions from particular instances. We must also observe, that this law of *conservatio virium vivarum* was not deduced either by Huyghens or any of the Leibnitzian school, by reasoning from more general principles. It was an expiscation of sameness in events, diversified by other circumstances. We do not recollect any author who has given what can be called a demonstration of it, deducing it from principles or laws still more general. We apprehend, that the present case of its truth has been so demonstrated by us. The *principle* is, that "a moving force is to be measured by the change of motion produced by it:" And the law to which this principle is applied is, that "the mutual repulsions of magnets are equal and opposite;" and the application is made by means of the "39th proposition of the first book of Newton's *Principia*." Our principle, which is the same with Sir Isaac Newton's second law of motion, is really an axiom of human thought. The proposition is the consequence logically drawn from this axiom; and the law of magnetism is an observed fact. We hope to shew by and bye, that this proposition, which is our n° 95 of Dynamics, is found to obtain in *every* instance that has been or can be given of the *conservatio virium vivarum*, and that this *conservatio* is only another way of expressing the proposition. Having done this, we shall not think ourselves chargeable with vanity when we say, that we have given the first demonstration of this famous law. We cannot refuse ourselves some satisfaction at having done this; because it has been so highly esteemed, chiefly for the support derived from it for the Leibnitzian measurement of the force of moving bodies by the *square of the velocity* which it communicates; whereas it is the logical consequence of the force being proportional to the *simple velocity*. We have only taken a weapon out of the hands of a plunderer, and restored it to its lawful owner, Sir Isaac Newton. *Non ita certandi cupidus, quam propter amorem:* For we must say,

Tu pater et rerum inventor, tu patria nobis
Suppeditas precepta, tuisque ex, inclute, chartis
Floriferis ut apes in saltibus omnia libant,
Omnia nos itidem depascimur aurea dicta
Aurea, perpetuâ semper dignissima vitâ.

We trust that our reader will not think that this minute discussion of the mutual actions of magnets or other repelling bodies, in which we have engaged him, has been thrown away, since it has enabled us to apprehend clearly a case of two such general laws as the *conservatio momentorum*, and the *conservatio virium vivarum*.

5. In the moment of greatest vicinity and common velocity, there is a certain determinate loss of the *vires vivæ*, or products of the matter by the square of the velocity; and this loss is proportional to the square of the relative motion. The *vires vivæ*, at the commencement of the mutual action, are $= A a^2 + B b^2$ (I.). In the moment of greatest proximity, the quantity of matter $A + B$ is moving with the common velocity $\frac{A a + B b}{A + B}$; therefore the *vires vivæ* are $= \overline{A + B} \times \frac{\overline{A a + B b}^2}{\overline{A + B}^2} = \frac{\overline{A a + B b}^2}{A + B}, = \frac{A^2 a^2 + B^2 b^2 + A B \times 2 a b}{A + B}$ (II.). — 39 *Vis viva* lost in the collision of unelastic bodies.

$$\text{I.} \times \overline{A + B} = A^2 a^2 + B^2 b^2 + A B \times a^2 \times b^2.$$
$$\text{II.} \times \overline{A + B} = A^2 a^2 + B^2 b^2 + A B \times 2 a b.$$
$$\text{Difference} \quad - \quad - \quad - \quad A B \times \overline{a - b}^2.$$

Loss of *vis viva* $= \frac{A B}{A + B} \times \overline{a - b}^2$, a quantity that is proportional to $\overline{a - b}^2$, the square of the relative velocity $a - b$.

Had the bodies been moving in opposite directions then (II.) $\times \overline{A + B}$ would have been $A^2 a^2 + B^2 - A B \times 2 a b$, and the difference from $\overline{A a^2 + B b^2} \times \overline{A + B}$ would have been $= A B \times \overline{a + b}^2$, proportional to the square of the relative velocity $a + b$.

Such is the fact; and we shall find it of importance in the great debate about the force of moving bodies. Let us inquire into the physical or mechanical cause of it. In the moment of common velocity, the bodies are nearer to each other than they are at the beginning and at the end of their mutual action. Therefore (when they are moving in one direction) the body A, which follows, has been retarded through a space which is greater than the space along which the preceding body B has been accelerated. But, because the simultaneous forces acting on the bodies along these unequal spaces are always equal, the area which measures the diminution of the square of A's velocity (Dynamics, n° 95.) must exceed the area which expresses the augmentation of the square of B's velocity, and there must be a loss of *vires vivæ*. Now, we learned above, that the mutual action is the same when the relative velocity is the same; and therefore the approximation, which is the occasion of this action, must be the same. And it is demonstrated in Dynamics, n° 95. that the area, whose abscissa is the space described, and ordinates the forces, expresses the square of the generated or extinguished velocity. This is evidently the relative velocity of the bodies, because they are brought to a common velocity in the instant of greatest proximity; that is, their relative velocity is destroyed. — Physical cause of this loss.

6. During the whole process, the common centre of position or gravity (A) is moving uniformly with the velocity — 40 The motion of the common centre of gravity is not changed by the mutual action.

(A) See the article Position in this *Supplement*; where it will be demonstrated, that the centre of gravity (determined in the usual manner) is the point by whose situation and motion we estimate with the greatest propriety the situation and motion of the assemblage, of which it is the centre: it is therefore called the centre of position. The reader is only desired at present to recollect, that the centre of gravity, or position of two bodies, is situated in the line joining their centres; and that its distance from each is inversely as their quantities of matter; and that the distance and motion of the centre is the medium or average of all the distances or motions.

Impulsion. velocity $\frac{Aa \pm Bb}{A+B}$. For the motion of the centre of position is the average of the motion of every particle of matter in both bodies. Aa is the sum of the motions of every particle of matter in A, and Bb is the sum of the motions of every particle in B, before the mutual actions began. Therefore $Aa + Bb$ is the whole motions when the bodies are moving in the same direction with their different velocities. The number of particles is $A + B$: Therefore, if the whole motions be equally divided among all the particles, the velocity of each must be $\frac{Aa + Bb}{A+B}$. This is the average motion, or the motion of the centre of position, deduced from the notion we wish to impress of the character of this centre, as the index of the position and motion of any assemblage of matter. This velocity may be deduced more easily from its geometrical property. It is a point so situated between A and B, that its distance from each is reciprocally proportional to the quantities of matter in A and B, as is well known of the centre of gravity. It is equally plain, that when the bodies are moving in opposite directions, the average velocity x must be $= \frac{Aa - Bb}{A+B}$. Thus we see that the motion of the centre of position, before the magnets have begun to act on each other, is the same with its motion when their mutual repulsion is the greatest; namely, at the moment of their greatest vicinity. It has continued the same during the whole process: for we have already seen, that the sum or difference of the momenta, or $Aa \pm Bb$, remained always the same; consequently $\frac{Aa \pm b}{A+B}$, or x, the motion of the centre, remains always the same. Therefore the proposition is demonstrated. It is, indeed, a truth much more general than appears in the present instance. *If any number of bodies be moving with any velocities, and in any directions, the motion of the centre of position is not affected by their mutual, equal, and opposite, actions on each other.*

41 The motions, in relation to the centre, are reciprocally as the bodies.

7. During the whole motion, the motion of the bodies relative to each other, is to the motion of one of them, relative to the centre of position, as the sum of the bodies is to the other body: For when they were moving with a common velocity, this velocity was the same with that of the centre; and they are then at rest, relative to each other, and relative to the centre. And because their distances from the centre are inversely as the bodies, their changes of distance, that is, their motions relative to the centre, are in the same proportion; and the sum of their motions relative to the centre is the same with their motions relative to each other. Therefore $A + B : A = a - b$: motion of B relative to the centre. Indeed we saw, that in their mutual action, the change of B's motion was $= \frac{A \times \overline{a-b}}{A+B}$, and the change of A's motion was $= \frac{B \times \overline{a-b}}{A+B}$.

42 The bodies separate with the same relative velocity which they approached.

Hence we learn, that while the centre moves uniformly, the bodies approach it, and then recede from it, with velocities reciprocally proportional to their quantities of matter. This will be found a very useful corollary. We may also see that their final velocity of mutual recess is equal to that of their first approach, or, their relative motions are the same in quantity after the action is over as before it began, but in opposite directions.

All these general facts, which are distinctly appreciable, and very perceivable, in this example of magnets, or electrified bodies, are equally appreciable in all cases of mutual repulsions, however strong these may be; and although the space through which they are exerted should be so small as to elude observation, and though the whole process should be completed in an insensible moment of time.

43 An interposed spring has the same effect with the mutual repulsions.

It scarcely needs any comment to make it clear that the very same changes of motion must take place, if a solid body A should come up to another solid body B, at rest, or moving more slowly in the same direction, or moving in the opposite direction; provided that there be a spring interposed between them, which may hinder A from striking B; for, as soon as A touches the spring, it begins to press it against B, and, therefore, to compress the spring. It cannot carry the spring before it, without the spring's pushing B before it. Pressure on B is required for this purpose. This is supplied by that natural power which we call elasticity, which is inherent in the spring, whether it be in motion or at rest. It is not in *action*, but in *capacity*, *faculty*, *capability*, *power*, or by whatever name we may choose to express the possession. The occasion required for its exertion is compression. This is furnished by the motion of A; for A cannot advance without compressing it. This inherent force of the spring is *known* to act with perfect equality at both ends, in opposite directions. It exerts equal and opposite pressures on A and on B; it diminishes the motion of A, and equally augments the motion of B (if both are moving that way). A is retarded, and B is accelerated; A is still moving faster than B; and therefore the compression and the consequent reaction of the spring increases, and still more retards A and accelerates B. After some time, both bodies, with the spring compressed between them, are moving with equal velocities; the spring, however, is strongly reacting on both, and must now cause them to separate; still retarding A and accelerating B—They must separate more and more, till the spring regain its quiescent form, and its elastic reaction cease entirely. During its restitution, its pressures are the same as during its compression; therefore, the whole change produced on each of the bodies must be double of what it was when the spring was in its state of greatest compression, and the bodies were moving with a common velocity. In short, the whole process in this example must be precisely similar to that of the magnets in every circumstance relating to the changes of motion in A and B. The common velocity must be $= \frac{Aa \pm Bb}{A+B}$. The final velocity of A must be $= a - \frac{2B\overline{a \mp b}}{A+B}$, and that of B must be $= b + \frac{2A\overline{a \mp b}}{A+B}$. The motion of the common centre must be unaffected by the action of the spring, and the motion of each body, relative to the centre, must be reciprocally as its quantity of matter, &c. &c.

We

Impulsion.

44 The changes of motion are produced by the inherent forces which connect the particles.

We apprehend that this process can scarcely be called impulsion; A has not struck B. The changes of motion can scarcely be ascribed to forces inherent in A or B, in consequence of their being in motion. Any person, not already warped by a theory, will (we think) ascribe them to a force inherent in the spring; inherent in it, whether at rest or in motion, and only requiring a *continued* compression as the proper opportunity for its continued exertion. This spring may be supposed to make a part of B, or of A, or of both; and then indeed, the force may be said to be inherent in either, or in both. But it is not the peculiar force inherent in motion, or in moving bodies *only*—it is the force of *elasticity*, inherent in part of the body, but requiring a continued *compression* for the production of a continued *repression*. The effect of this reaction is modified by the very occasion of the compression. This may be the elasticity of another spring. In this case it will only compress that spring—It may be the advance of a body in motion; the reaction produces a retardation of that motion; it may be the obstacle of a quiescent body—It will give it motion; or, it may be the obstruction by a body moving more slowly away than the spring is pressed forward—it will accelerate that motion. Thus, in all these cases, we cannot help distinguishing the immediate cause of these changes of motion from the supposed force of a moving body. Nay, the process of motion is similar, even when we suppose that the spring is not a thing external to the body, although attached to it; but that the whole body, or both bodies, are springy, elastic, and therefore compressible. As soon as the bodies come into sensible contact, compression *must* begin; for we may suppose the bodies to be two balls, which will therefore touch only in one point. The mutual pressure, which is necessary in order to produce the retardation of A, and the acceleration of B, is exerted only on the foremost particle of A, and the hindmost particle B; but no atom of matter can be put in motion, or have its motion any way changed, unless it be acted on by an adequate force. The force urging any individual particle, must be precisely competent to the production of the very change of motion which obtains in that particle. Except the two particles which come into contact in the collision, all the other particles are immediately actuated by the forces which connect them with each other; and the force acting on any one is generally compounded of many forces which connect that particle with those adjoining. Therefore, when A overtakes B, the foremost particle of A is immediately retarded—the particles behind it would move forward, if their mutual connection were dissolved in that instant; but, this remaining, they only approach nearer to the foremost striking particles, and thus make a compression, which gives occasion for the inherent elasticity to exert itself, and, by its reaction, retard the following particles. Thus each stratum (so to conceive it), continuing in motion, makes a compression, which occasions the elasticity to react, and, by reacting, to retard the stratum immediately behind it. This happens in succession: the compression and elastic reaction begin in the anterior stratum, and take place in succession backward, and the whole body gets into a state of compression. Things happen in the same manner in B, but in the contrary direction, the foremost strata being the last which are compressed. All this is done in an instant (as we commonly, but inaccurately speak), that is, in a very small and insensible moment of time; but in this moment there is the same gradual compression, increase of mutual action, greatest compression, common velocity, subsequent restitution, and final separation, as in the case of bodies with a slender spring interposed, or even in the case of the mutually repelling magnets. In all the cases, the changes of motion are produced by the elasticity or the repulsion, and not by the transfusion of the force of motion. The changing force is indeed inherent in the bodies, but not because they are in motion; the use of the motion is to give occasion, by continued compression, for the continued operation of the inherent elasticity. The whole process may be very distinctly viewed, by making use of bodies of small firmness, such as foot-balls, or blown bladders. If blown bladders are used, each loaded with sand, or something that will require more force, and consequently more compression to impel it forward; we shall observe the compression of both to be very considerable, and that a very sensible time elapses during the process of collision. This may even be observed very distinctly in a foot-ball, which is always seen to rest a little on the toe before it flies off by the stroke. When one foot-ball is strongly driven against another, they plainly adhere together for some time, and then the stricken ball flies off.

45 Internal process of change through the substance of each body.

If we return to the example of the two balls with the spring interposed, we may make some farther useful observations. When the spring is in its state of greatest compression, and the balls are moving with a common velocity, we can suppose that the spring is arrested in that situation by a catch. It is evident that the two bodies will now proceed in contact with this velocity, which we have shewn to be $= \frac{Aa \mp Bb}{A+B}$.

46 Nature of imperfect elasticity.

Now, in the constitution of such masses of tangible matter as we have the opportunity of subjecting to our experiments, we find a state of aggregation which very much resembles this. Some bodies are almost perfectly elastic, that is, when their shape is changed by external pressure; and that pressure is removed, they recover their former shape completely, and they recover it with great promptitude. Glass, ivory, hard steel, are of this kind. But most bodies either do not recover it completely, or they recover it very slowly—some hardly recover it at all. A rod of iron will, when considerably bent, not nearly recover its shape; a rod of lead still less; and a rod of soft clay will hardly recover it in any degree. These, however, are but gradations of one and the same quality: if the quiescent form of a body is very little disturbed, it will recover it again. Thus, a common soft iron wire of No 6. and 12 inches long, if twisted once round, will return completely to its original form, and will allow this to be repeated for ever; but if it be twisted 1½ turns, it will untwist only 1: and in this new form it will twist and untwist one turn as often as we please. Even a rod of soft clay $\frac{1}{5}$th of an inch in diameter, and 7 feet long, will bear one twist as often as we please: but if twisted 4 times, will untwist itself only one turn, and will do this as often as we choose. In short, it appears that the particles of bodies, usually called unelastic, will admit a small change of distance

or

or fituation, and will recover it again, exhibiting perfect elafticity, in oppofition to very fmall forces; but if they are forced too far from this fituation, they have no tendency to return to it completely, but find intermediate fituations, in which they have the very fame connections with the furrounding particles; and in this new fituation they can again exhibit the fame perfect elafticity, in oppofition to very fmall forces. Mr Coulomb conceives fuch bodies to confift of elaftic particles: they manifeft perfect elafticity, fo long as the forces employed to change their fhape do not remove the particles from their prefent contacts; but if they are removed from thefe, they flide on to other fituations, where they again exhibit the fame appearances. To underftand this fully, the reader may confult the article Boscovich of this *Supplement*—The fact is fufficient for our prefent purpofe. Now, in this variable conftitution, where the particles may take a thoufand different fituations, and ftill cohere, it is plain, that when a body has been dimpled by compreffion, the particles have nothing to bring them back to their firft fituation when the compreffing force is removed: the utmoft elafticity to be expected, is that which will not extend to one fhift of fituation; therefore, the reftitution is altogether infenfible. This is the cafe with all foft bodies, fuch as clay—the fame quality is manifefted in all ductile bodies, fuch as lead, foft iron and fteel, foft copper, foft gold.

47 Effect of this collifion.

Now let one of thefe bodies ftrike another. The compreffion, or the fliding of the particles over each other, requires force, or mutual preffure—This being accompanied by a reaction perfectly equal, muft operate, during the compreffion, precifely as the equal repulfive forces did. It will take as much momentum from A as it gives to B; fo that $\text{A}\,a \mp \text{B}\,b$ will remain invariably the fame, and a common velocity will at laft obtain, $= \frac{\text{A}\,a \mp \text{B}\,b}{\text{A} + \text{B}}$. The compreffion can proceed no farther, and the two bodies muft now proceed in contact with this velocity.

And thus we fee, that in the cafe of compreffible, but unelaftic bodies, the changes of motion are produced by the cohefive forces inherent in the bodies; but not inherent in them becaufe they are in motion. We fee clearly in this way, how the pendulum ufed by Robins and his followers gave a true meafure of the velocity of the ball. All the while that it was penetrating into the pendulum, overcoming the cohefion as it went in, this cohefion was acting equally in both directions. While the fibre was breaking, it was pulling both ways; it was holding back the ball which was breaking it, and it was pulling forward the parts to which it ftill adhered; and when it broke at laft, it had produced equal effects on the ball and on the pendulum in oppofite directions. By fuch a procefs, the pendulum was gradually accelerated, and acquired its utmoft velocity when the ball had ceafed to penetrate: Therefore, this velocity muft be $= \frac{\text{A}\,a}{\text{A} + \text{pend}^{\text{m}}}$.

What fhould we now expect to happen in the collifion of bodies? Such bodies as exhibit perfect elafticity, when examined by bending, or other fit trials, fhould have their motions changed precifely like the magnets, or bodies which repel or avoid each other at fenfible diftances. Bodies which exhibit no elafticity whatever, fhould continue in contact after collifion. The common velocity in thefe fhould be $\frac{\text{A}\,a \mp \text{B}\,b}{\text{A} + \text{B}}$. The perfectly elaftic bodies fhould fuftain changes of motion which are precifely double of the changes fuftained by unelaftic bodies, and fhould feparate after collifion with a relative velocity of recefs or feparation, precifely equal to their relative velocity of mutual approach. And bodies poffeffing imperfect elafticity, fhould fuftain changes of motion, which differ from the changes on unelaftic bodies, precifely in proportion to the degree of elafticity which they are *known* to poffefs. And, laftly, if the changes of motion which obtain in the collifion of bodies, are precifely thofe which would refult from the operation of thofe inherent forces of elafticity and cohefion, NO OTHER FORCE WHATEVER CONCURS IN THEIR PRODUCTION: For we know that thofe forces *do operate* in the collifion; we fee the compreffion and reftitution which are their effective caufes, and their immediate effects. If any other force were fuperadded, we fhould fee its effects alfo, and the motions would be different from what they are.

Now the fact is, that *we have never feen a body that is not, in fome degree, compreffible.* It has not pleafed the Almighty Creator to make any fuch here below. Affuredly He has not found fuch to be of ufe for the purpofes He had in view in this our fublunary world. We know of no body that is perfectly unchangeable in its fhape and dimenfions. It is therefore no lofs whatever to us, although we fhould not be able to fay *à priori* what their motions will be in collifion. We cannot even fairly guefs them, by reafoning from what we obferve in other bodies: For it is juft as likely that their motions may refemble thofe of perfectly elaftic bodies as thofe of unelaftic bodies; for we find that bodies of the moft extreme hardnefs are generally highly elaftic. Diamond, cryftal, agate, quartz, and fuch like, are the moft elaftic bodies we know. Philofophers, however, rather think that the motions of perfectly hard bodies will refemble thofe of unelaftic bodies; becaufe elafticity fuppofes compreffion. We do not pretend to fay with confidence, what would be the motion of a fingle atom of matter (which cannot admit of compreffion) which is hit by another in motion. We fee all the particles of terreftrial matter connected with each other by certain modifications of the general force of cohefion, fo as to produce various forms of aggregation; fuch as aërial fluidity, liquid fluidity, rigidity, foftnefs, ductility, firmnefs or hardnefs; all of which are combined with more or lefs elafticity. Thefe tangible forms refult from certain pofitive properties of the material atoms of which the particles are compofed; and, in all the cafes which come under our obfervations, thefe properties produce preffures of one kind or another; all of which are moving forces. They are inherent in the particles and atoms: therefore when fuch atoms are in motion, thefe forces are in a condition which affords occafion for a *continuation* of this preffure that is competent to the production of motion in another particle. But what would be the event of the meeting of atoms divefted of fuch forces, we profefs not to know, or even to conceive.

The fact alfo is, that all the changes of motion, commonly called impulfions, *which have been obferved*, are precifely precisely such as have been described. Unelastic bodies proceed in contact with the velocity $\frac{Aa \pm Bb}{A + B}$. Perfectly elastic bodies separate after collision, and each sustains double of the change that is sustained by an unelastic body. Bodies of imperfect elasticity differ from the two simple cases, precisely in the proportion of the elasticity discoverable by other trials. The mutual actions are observed to be in the proportion of their relative motions, whatever the real motions may be. For not only are the changes of progressive motion exactly in this proportion, but the compressions and changes of figure, which we consider as the immediate occasions of those actions, are also observed to be in the same proportions, *in all cases that we can observe and measure with accuracy.* All these things can be ascertained with great precision by means of the collision of pendulous bodies in the way pointed out by Sir Christopher Wren (a method attributed by the French to their countryman Mariotte, but really invented by Wren, and exhibited to the Royal Society of London the week after he communicated his theory of impulsion).

48
The observed effects of collision are perfectly conformable to the propositions now established.

49
Extensive proof of the universality of equal action and reaction.

We must also infer from these facts, that the actions of bodies on each other are mutual, equal, and opposite. This is really an inference from the phenomena, and not an original or first principle of reasoning. The contrary is conceivable, and therefore not absurd. In the same way that we can conceive a magnet repelling iron, without imagining that the iron repels the magnet, we may conceive a golden ball capable of impelling a leaden ball before it, without conceiving that the leaden ball will impell the golden ball. We do not find this easy indeed; because the contrary is so familiar, that the one idea instantly brings the other along with it. We apprehend it to be impossible to demonstrate, that a leaden ball will not stop as soon as it hits the golden ball, or *vice versa*. But all our experience shews us, that the pressures exerted in contact are mutual, equal, and opposite. The same thing is observed in the forces which connect the parts of bodies. A quantity of sand or water balanced in a scale will remain in equilibrio in whatever way it is stirred about; its parts always exert the same pressure on the scale: so does a body suspended by a string or resting on the scale, by whatever points it is supported. This could not be if the particles did not exert mutual and equal forces; nor could the phenomena called impulsions be what they are, if the pressures occasioned between the particles by the compressions and dilatations were not mutual and equal. This law of action and reaction must be admitted as universal, though contingent, like gravity. Doubtless it results from the properties which it has pleased the great Artist to give to the matter of which He has formed this world. There is one way in which we can conceive, most distinctly, how this may be a universal property of matter. If we grant the reality of attractions and repulsions *e distanti*, and suppose that every primary atom of matter is precisely similar to every other atom in all its properties, and that this assemblage of properties constitutes it a material atom; it follows, that every atom exerts the same attractions and repulsions, or has the same uniting and evasive tendencies, and then the law of action and equal reaction follows of course. This is surely the very notion that any person is disposed to entertain of the matter. And if mechanical force and mobility are the qualities which distinguish what is material from mind or other immaterial substances, the law of equal and contrary reaction seems nearly allied to the class of first principles.

Of all the phenomena that indicate this perfect equality of action and reaction, the most susceptible of accurate examination is the sameness or equality of action when the relative motions are equal. Now there is no phenomenon more certain than this. In consequence of the rotation of the earth round its axis, and its revolution round the sun, it is plain that all our experiments and observations are on relative motions only. Now, we not only find that the actions of two bodies subjected to experiment are equal when the relative motions are equal, but we find that all our measures of action on a single body are proportional to the apparent motions which they produce. It requires precisely the same force to impel a ball eastward, westward, south, or north, at 12, or 3, or 6, or 9 o'clock: yet the real motions are immensely different in all these cases, and it is only the relative motions that have the proportions which we observe. Another very important point deducible from our experiments is, that the same *pressure* produces the same change of motion, whatever may be the velocity. We know this by observing, that when the mutual dimpling or compression is the same, the change of motion is the same, whatever be the hour of the day. This could not be if it required a greater pressure to change the velocity 100000 into 100001, than to change the velocity 1 into the velocity 2. Yet this is one of Leibnitz's great metaphysical arguments for proving that the force accumulated, and now inherent, in a moving body, is proportional to the square of its velocity. We beg that this may be kept in remembrance.

It must be granted, that what we have already said on the subject of impulsion may be called an *explanation*; for it deduces the phenomena from general and unquestionable principles, and from acknowledged laws of Nature. The only principle used is, that a moving force is indicated, characterised, and measured, by the motion which it produces. It is an acknowledged law of Nature, that pressures are moving forces; also, that moving forces appear in cases where we observe neither pressures nor impulsions, and which we call repulsions or evasive tendencies; that these are mutual and equal: and we have shewn, how a certain set of changes of motion result from them, and have stated distinctly the whole process: we shewed, that these phenomena are similar to those of common impulsion; and we then shewed in what manner the motion of a body *gives occasion* to the exertion of various moving forces, called *elasticity*, *cohesion*, &c. and that this exertion must produce motions similar to those produced by repulsions *e distanti*; and, lastly, we inferred, from the perfect sameness of those results with the actual phenomena of impulsion, that those corpuscular forces are the immediate and *only* causes of the changes called impulsions, and commonly ascribed to a *peculiar* force inherent in a moving body.

50
Why does the philosopher attempt to explain gravitation, &c. by impulsion?

From a collective view of the whole, we think it clear, that the opinion that impulsion is the sole cause of motion is unwarranted. We see that the phenomena of impulsion are brought about by the *immediate* operation of pressure; and we see numberless instances of pressure, in which we cannot find the ſmalleſt trace of impulſion. It is therefore a moſt violent and unwarranted opinion, which aſcribes to repeated unperceived impulſions all theſe ſolicitations to motion by which, or in conſequence of which, the motions of bodies are affected by diſtant bodies, or bear an evident relation to the ſituation and diſtance of other bodies; as in the examples of planetary deflection, terreſtrial gravitation, magnetical and electrical deflexions, and the like. There is nothing in the phenomenon of the preſſure of gravity that ſeems to make impulſion more neceſſary or more probable than in the preſſure of elaſticity, whether that of a ſpring or of an expanſive fluid. The admiſſion of an unperceived fluid to effect thoſe impulſions is quite unwarranted, and the explanation is therefore unphiloſophical, even although we ſhould perceive intuitively that an atom in motion will put another into motion by hitting it. We apprehend that this cannot be affirmed with any clear perception of its truth.

51 Impulſion is ſuppoſed to be better underſtood and more familiar.

On the whole, therefore, we muſt aſcribe that contented acquieſcence in the explanations of gravitation, and other attractions and repulſions, by means of impulſe (if the acquieſcence be not pretended), to the frequency and familiarity of impulſion, and perhaps to the perſonal ſhare and intereſt we have in this mode of producing motion. We know that it is always objected that nothing is explained, when we ſay that A repels B, or that B avoids A; but we muſt ſay in return, that nothing is explained, when we ſay that A impels B by hitting it, or that B flies away from the ſtroke. Why ſhould it not be allowed to uſe the term repelling power, when it is allowed to uſe the term impelling power, the force of impulſe, inertia? All theſe terms only expreſs phenomena. Does the word body expreſs any more?

52 It is not better underſtood.

The maxim, that a body cannot act *where* it is not, any more than *when* it is not, is a quaint and lively expreſſion, and therefore has conſiderable effect: It may be granted; for we apprehend that we underſtand ſo little about *when* and *where*, that we cannot demonſtrate the affirmative or negative in either caſe, and that they are on a par with reſpect to our knowledge of them. We can have no doubt, however, of the fact, that our mind can be affected by an external object that is merely recollected. And we apprehend, that we know nothing of the difference between body and mind but what we have learned by experience. Body, for any thing that we aſſuredly know to the contrary, may affect, or be affected by, a diſtant body, as well as mind may be. It is therefore worth while to pay ſome farther attention to the phenomena, in order to ſee whether this experience is ſo univerſal and unexcepted as is believed. As Mr Cotes, and many of Newton's diſciples, are accuſed of explaining many phenomena by attraction and repulſion which their opponents affirm to be caſes of impulſion; it is not impoſſible but that ordinary obſervers, who have no preconceived theories, may imagine impulſions to obtain in caſes where a more accurate inſpection would convince them that no impulſion has happened.

53 Enquiry into the familiarity of impulſion. Inſtances of a foot-ball.

When we kick away a foot-ball, we conſider it as a ſort of ſolid continuous body; yet we know that it muſt be filled with compreſſed air. It may not be impoſſible to have it of its round ſhape without being ſo filled: but we know that, in this condition, it would not fly away from our foot by the ſtroke; we ſhould only force in the ſide which we kick, and the flaccid ſkin would lie at our feet. But when it is filled with ſtrongly compreſſed air, we can form to ourſelves a pretty diſtinct notion how it is made to move off. Our foot preſſes on a part of the ſkin: this compreſſes the air againſt the anterior part of the bag, and forces it away. If we reflect more ſeriouſly on the proceſs, we can ſtill conceive it clearly enough, by thinking on a row of aereal particles, reaching from the part ſtruck by the foot to the anterior part, each touching the other, and therefore forcing the anterior part forward. The air is conceived to conſiſt of a number of little ſpherules in contact, each of which is compreſſible; and we think the operation illuſtrated by ſuppoſing each to be like a little veſicle or bladder. This we believe to be the uſual way of conceiving the conſtitution of expanſive fluids: But this will not agree at all with the known properties of air; for it can be ſtrictly demonſtrated, that if ſuch a collection of elaſtic veſicles be compreſſed into the half of their ordinary bulk, every veſicle will be changed from a ſphere into a perfect cube, touching the adjoining cubes in every point of its ſix ſides, and ſtrongly preſſed againſt them. It can alſo be demonſtrated, that if a leaden cube of one inch be included in the box, and placed with its ſides parallel to the ſides of the box, and the compreſſion be then made, all the little cubic veſicles will acquire the ſame poſition. If the box be now turned upſide-down, it can be demonſtrated that the weight of this leaden cube will not be ſufficient for overcoming the reſiſtance of the compreſſed cubes. This compreſſed maſs will not be fluid, but will require a very conſiderable force to preſs the leaden cube through it, juſt as we find ſuch a force neceſſary for moving a body through melted glaſs: the particles no longer ſlide on each other like uncompreſſed ſpherules; each will require about half of the compreſſing force, in order to overcome the friction, or obſtruction like friction, produced in ſliding along the ſurface of the contiguous cubes. But we know that air remains perfectly fluid, although vaſtly more compreſſed than this. This, therefore, cannot be like the conſtitution or form of air. Moreover, it is well known that air has been made ten times denſer than its ordinary ſtate, and is then perfectly fluid. It has alſo been made a hundred times rarer, and it ſtill remains perfectly fluid. In this ſtate its particles muſt be ten times farther removed from each other than in the former ſtate, of a thouſand times greater denſity. Yet we know that this rare air is compreſſed with a force equal to the weight of a ſtratum of mercury $\frac{1}{3}$d of an inch in thickneſs, and that if $\frac{1}{3}$d of this preſſure be removed, it will expand till it is 150 times rarer than common air; that is, there is ſome force which puſhes the particles ſtill farther from each other. This force evidently extends beyond the tenth particle of air that is made ten times denſer than common air. Therefore the elaſticity of air does not ariſe from the contact of particles, which are elaſtic like blown up bladders, but from ſome force which extends beyond the adjoining particles. There is no greater reaſon, therefore, for ſuppoſing, that the particles of air touch each other, than for ſuppoſing that the two magnets touch each other becauſe they repel. A row of magnets floating on quickſilver, and placed with their ſimilar poles fronting

ing each other, and very near, will tend to separate, and they require to be held in by a stop put at each end of the canal; and if one stop be gradually withdrawn, the magnets will all separate, and exhibit the general mechanical effects of a row of aereal particles separating by the removal of pressure. There seems, therefore, to be the same necessity for the operation of an intervening impelling fluid for producing this separation or elasticity of the aereal mass, as for separating the magnets.

Is very doubtful.

The result of these remarks seems to be, that the impulsion of a foot-ball is not brought about in the way that is commonly imagined, by the excitement of corporeal pressure at the points of contact of the two foot-balls. For we see it almost demonstrated, that the progressive motion of the anterior part of one of the balls has been produced without contact, or, at least, by the *intervention* of repulsions acting at a distance.—May not this obtain, even in the points in which we suppose the two balls actually to touch, in the act of impulsion?

54 Many cases of doubtful contact.

But farther—Every person has observed the brilliant dew drops lying on the leaves of plants. Every person acquainted with Newton's optical discoveries, must be convinced that the dew-drop is not in mathematical contact with the leaf; if it were, it could have no brilliancy. Most persons have observed the rain drops of a summer shower fall on the surface of water, and roll about for a few seconds, exhibiting the greatest brilliancy. They cannot, therefore, be in mathematical contact with the water. There must be a small distance between them, and therefore some force which keeps them asunder, and carries the weight, that is, counteracts the downward pressure of the rain drop. We know that some insects with long legs can run about on the surface of water; and if we lift them carefully, and set them on glass, their feet do not wet it. Put a little spirit of wine into this water, and make it lukewarm, and the insect instantly sinks up to the belly, and cannot move about as before: Its feet will now wet a glass. A well-polished steel needle, even of considerable size, if perfectly clean and dry, will float on water without being wetted: It is observed to make a considerable depression on the surface of the water, just as a heavy bar of iron would make when laid on a feather bed—the needle displaces a quantity of water equal to itself in weight, yet does not touch it, for it is not wetted. If it be previously wetted, it will not displace any water, and will not float. There is something, therefore, which keeps the water at a distance from the feet of the insect, and from the needle, exerting a certain upward pressure on them. The pressure and the reaction are indeed very small; but they would produce a very sensible motion if continued sufficiently long in proper circumstances. Here would be a production of motion, which most persons would call an impulsion—yet there would be no stroke, no contact, and therefore no true impulsion.

55 Very remarkable case of convex lenses falsely seeming to touch.

We now beg the reader to attend minutely to Newton's famous experiment with the object glasses of long telescopes, which we have mentioned circumstantially in the article OPTICS, *Encycl.* nº 63—68.

When the upper glass is very thin and light, no colour appears at the point of contact: but by pressing it down with sufficient force, we shall have a black or unreflecting spot in the middle, surrounded by a silvery ring, and then by a series of rings of various colours, according to the distance between the parts of the glasses where the colours appear. Newton has counted 50 of these rings. He shews, by a careful computation from the known figure of the glasses, that the differences between the distances which exhibit these colours are all precisely equal, and that each is about $\frac{1}{89000}$ of an inch. Therefore, supposing that the glasses are in mathematical contact where the unreflecting spot appears, making one continuous mass of glass, their distance at the outermost ring must not be less than $\frac{50}{89000}$ of an inch, or $\frac{1}{1780}$ of an inch. Therefore, when one glass carries the other, without any appearance of colour at the middle, we must conclude that there is a repulsion exerted between the nearest parts, at a distance not less than $\frac{1}{1780}$ of an inch, sufficient for supporting the upper glass. It requires an increase of pressure to produce the first appearance of colour; and when the pressure is still more increased, new colours appear in the middle, and the colour formerly there is now seen in a surrounding ring; these multiply continually, by new ones spreading from a central spot. A great pressure at last produces the unreflecting spot in the centre, which, unlike to all the coloured spots which had emerged in succession, is sharply defined, and never round, but ragged, and it is immediately surrounded by a bright silvery reflection. The shape of this spot depends on the figure of the surfaces; for, on turning the upper lens a little round its axis, the inequalities of the edge of the spot turn, in some degree, with it. This seemingly trifling remark will be found important by the mechanician: A still farther increase of pressure enlarges the unreflecting spot, and the dimensions of all the rings—When the pressure is gradually withdrawn, the rings shrink in their dimensions, the unreflecting spot disappears first, and each ring in succession contracts into a spot, and vanishes. Here we have, by the way, an explanation of the brilliancy of dew-drops: they come so near, perhaps, that the nearest point reflects the silvery appearance—but they do not touch; the instant that they touch a wetted part, making one mass of transparent matter, all brilliancy is gone.

56 They repel each other;

Here then are incontestible proofs of a force, be its origin what it may, which keeps the glasses asunder, and even causes them to separate; which manifests itself by withstanding pressure; and therefore is, itself, a pressure, or equivalent to a pressure—It varies in its intensity by a change of distance; but we have not been able to ascertain by what law. It must not be measured by the simple variation of the external pressure; for since we see that, even before any colour appears in the centre, the weight of the upper lens is supported, we must conclude that the glasses are exerting at least an equal force all around the circumference of the outermost ring. It is evident, that the computation of the whole force, exerted over all the coloured surface, must be difficult, even on the simplest hypothesis concerning the law of repulsion: we can only say that it increases by a diminution of distance. It is very easy to compute the increase of external pressure, which would suffice if the repelling force were equal at all distances; or if it varied according to any single power of the distances. We have tried the inverse simple,

 duplicate,

Impulsion. duplicate, and triplicate ratio; but the fact deviated widely from them all. The repulsion does not change nearly so much as in the simple inverse ratio of the distances, if the glasses be supposed to touch in the whole surface of the unreflecting spot. But we found, that if we suppose them separated, though at a distance equal to forty times the difference of distance at which the colours change, that is, $\frac{1}{11}\frac{1}{1}$ of an inch, the pressures employed in the experiment accord pretty well with a repulsion inversely as the distance, but still with a very considerable deviation in the great pressures. In the course of a number of experiments with a favourite pair of lenses, we broke the uppermost by too strong a pressure. We then cut out of it, with a lapidary's hollow drill, a piece of $\frac{1}{4}$ of an inch in diameter, and perfectly round, and we squeezed it on the other by a measured pressure, till we produced a colourless spot of nearly $\frac{1}{6}$th of an inch in diameter, with a silvery margin. Computing from this, we thought ourselves warranted to say, that not less than 800 pounds are necessary for producing a black spot of one inch square!

57 And may impel without touching.

Now, what is the consequence of all this in the doctrine of impulsion? Surely this:—If a lump of this glass strike another lump, and put it in motion, and if the mutual pressure in the act of collision do not exceed 700 pounds on the square inch, the motion has been produced without mathematical contact, and the production can no more be called impulse than the motion of the magnet in our first experiment. The changes of motion have been the operation of moving forces, similar to the force of magnetism; and if a stream of truly impelling fluid be necessary for producing the motion of the magnet, it is equally necessary for producing the motion of the piece of glass.

It may be said here, that we cannot compare impulse and pressure. A slight blow will split a diamond which could support a house. A slight blow may therefore be enough for exciting all the pressure necessary for producing mathematical contact. We must here appeal to what every man feels on this occasion. We doubt exceedingly whether any person will think that, when one piece of glass gives another a gentle blow, and puts it into motion, with the velocity of a few inches per second, a blow which he distinctly hears, there has been exerted a pressure at all approaching to 800 pounds per square inch.—We have suspended a pair of lenses, by an apparatus so steady and firm, that they could touch only at the centres of each surface; and, having placed ourselves properly, we could see, with sufficient distinctness, the momentary appearance of the coloured spot at the instant of collision. We saw this, with the fullest confidence that it was of no considerable breadth in a moderate stroke, and that it was very sensibly broader when the stroke was more violent. We did not trust our own eye alone, but shewed it to persons ignorant of philosophy, and even to children, often without telling them what to look for, but asking them what they saw. From all the information that we could gather, none of the pressures came near to what must have been necessary for producing the black spot. This could not be mistaken: for although the outer rings are but faint, there are five or six near the centre which are abundantly vivid for affecting the eye by the momentary flash. Besides, the dimensions of the lenses, and the weight of the metal cells in which they were fixed, were such as must have caused them to split before the black spot could be produced in the centre.

And certainly do so, even in violent strokes.

These things being maturely considered, we imagine that few persons will now doubt the justice of our assertion, that in all these examples, the motions have been produced without mathematical (or rather geometrical) contact.—And we imagine also, that few will refuse granting that this is not peculiar to glass, but obtains also in the collision of other bodies. We have not thought of any method for putting this beyond doubt; but we have better reasons than mere likelihood for being of this opinion. Every one acquainted with the Newtonian discoveries in optics, knows that this curious appearance of the coloured rings is the consequence of the action of transparent bodies on the rays of light, by which these are bent aside from their rectilineal course, and that this deflection takes place at a distance from the diaphanous body; a distance which the sagacity of the great philosopher has enabled us to measure. Now, it is known that metals and other opake bodies produce the very same deflections of the rays, bending them toward themselves at one distance, and from them at other distances; in short, attracting or repelling them as the distance varies. Nothing but prepossession can hinder a person from ascribing similar effects to similar causes; and, therefore, thinking it almost certain, that this mutual repulsion is not peculiar to glass, but common to all solid bodies.

To all this we may surely add the celebrated experiment of Mr Huyghens; in which it is evident, that a smooth plate of metal attracts another, even although there be a silk fibre interposed between them. (See Phil. Transf. n° 86). Is it not highly probable, that at a smaller distance the bodies repel each other? For we observe, that metals, as well as transparent bodies, attract the rays at one distance and repel them at another.

58 Impulsion is not so familiar as is believed.

Surely our readers will now grant, that the production of motion by impulsion, as distinguished from the production by action *e distanti*, is not so familiar a phenomenon as was imagined, and that it may even be said to be rare in comparison: for the instances of moderate impulses are numberless. The claim of this mode of explaining difficult phenomena by impulsion, has therefore lost much of its force: and we see much less reason for calling in the aid of invisible fluids, in order to *explain* the action of gravity, magnetism, and electricity.

59 Still greater doubts. Observations on a soap bubble.

But we have still more important information from the optical discovery of Newton. Let the reader turn again to Optics, *Encycl.* n° 65, and read the account of the phenomena exhibited by the soap-bubble. The bubble is thinner and thinner as we approach the very uppermost point of it. It also exhibits luminous rings, which vary in their colour, in the same order as in the space between the lenses. These rings come to view in the same manner. First, a coloured spot appears in the summit of the bubble; this becomes a ring, and is succeeded by another spot, as the bubble grows thinner in that part, by the gradual subsiding of the watery film. At last a black spot appears at top, well defined, but of irregular shape, surrounded by a silvery ring. This spot, when viewed very narrowly, is observed to reflect a very minute portion of light, without

Impulfion.

out *feparating* the differently colorific rays of which it confifts; but it *contains* them all, as may be proved by viewing it through a prifin. After fome little time, the bubble burfts.

Surely we muft infer from this, that there is a certain thicknefs of the tranfparent plate which renders it unfit for the vivid reflection of light. Does it not legitimately follow from this, that the unreflecting fpot between the lenfes ceafes to entitle us to fay, that they are in contact in that place? All that we can conclude from its appearance is, that the diftance ftill between the glaffes is too fmall to fit the place for the vivid reflexion of light. This conclufion is indifputable. Were it refufed, we are furnifhed with an inconteftible proof by the fame bountiful hand. Newton afcribed the colours to the reflection of the plate of air between the glaffes, and expected the ceffation of them when the air is removed. His friend Mr Boyle had lately invented a commodious air pump. The trial was made, and young Newton found himfelf miftaken; for the colours ftill appeared, and he even thought them more brilliant. He then tried the effect of water, expecting that this would diminifh their luftre. So it did; and he found that the dimenfions of the rings were diminifhed in the proportion of 4 to 3; namely, the proportion of the refractions of glafs and water. By this time Newton had difcovered the curious mechanical relation between bodies and the rays of light; and his mind was wholly abforbed by the difcovery, and by the revolution he was about to make in the mathematical doctrines of optics. Unfortunately for us, he did not, at that time, attend to the mighty influence which the difcovery would have on the whole of mechanical philofophy, and therefore occupied himfelf only with fuch phenomena as fuited his prefent purpofe. A moft important phenomenon paffed unnoticed. In repeating Sir Ifaac Newton's experiments, we found that the diameters of the rings decreafed in the proportion of 4 to 3 only in certain circumftances. When the upper lenfe was preffed on the other by a heavy metal ring, fo as to produce three or four coloured rings, we found, that when water got between them, fometimes no colours whatever appeared; fometimes there was a ring or two, and the diameters were diminifhed in a much greater proportion than Newton had affigned. Well affured of the extreme nicety of all his proceedings, we were much puzzled with this difcrepancy, and mentioned it to a moft refpectable and intelligent friend, the late Dr Reid of the univerfity of Glafgow, a mathematician and naturalift of the firft rank. He thought it not improbable that the glaffes feparated from each other, lifting up the weight, by attracting the water into the interftice, in the fame manner that we obferve wood to fwell with moifture. We immediately got an apparatus which compreffed the glaffes by means of four fcrews; and now we faw Newton's proportion moft ftrictly obferved. But in profecuting the experiment, we found that the introduction of the water *always* effaced a very fmall fpot. This happened after precautions had been taken to prevent all feparation of the glaffes. As the proportion of 4 to 3 has a relation to refractive power, although we have not been able to deduce it as a neceffary confequence, we neverthelefs confidered it as a fufficient proof, that the diftance of the glaffes *had not changed* by introducing the water between them. Therefore we think ourfelves well entitled to conclude, that the difappearance of the black fpot was not owing to a feparation of the glaffes, which admits the water into the empty fpace; and we affirm, that before the entry of the water, there was room for it in the place which reflected no light; that is, that although the glaffes were preffed together with a very great force, they were not in contact.

Remark.

It deferves remark, that in endeavouring to produce the black fpot, when water is between the glaffes, we found great and unaccountable anomalies. Sometimes a moderate increafe of preffure produced it, and fometimes we were not able to produce it by any preffure. Several lenfes were broken in the trial. We are led to think that the thicknefs which gives the filvery reflection is much greater than the 8900th part of an inch, and that it is not the fame in all glaffes. But we were interrupted in thefe experiments, and indeed in all active purfuits, by bad health, which has never permitted their renewal. The fubject is of great importance to the curious mechanicians, and we earneftly recommend it to their attention. There is fomething very remarkable in the abrupt ceffation of the coloured reflection. At a certain thicknefs *all* colours are reflected, without feparation, producing the whitenefs of filver. The fmalleft diminution of it hinders the *vivid* reflection of *all* colours, and then there feems to fucceed a thicknefs which equally reflects a fmall proportion of *all* without feparation. The fineft polifh that can be given to glafs in the tool of the artift, leaves irregularities which occafion the irregular ragged figure of the fpot. It is worth trying, whether fmoothing the furfaces (both) by a foftening heat will remove this ruggednefs. If it does, without deftroying the fharp termination, it will prove the abrupt paffage from *effe* to *noneffe*.

The laft remark to be made on this important experiment in optics is, that the diftance between the glaffes which is unfit for vivid reflection, cannot be determined by means of the other meafurable intervals. It may be equal to many of them taken together. The fame muft be granted with refpect to the thicknefs of the black fpot on the top of the foap bubble. We attempted to meafure this thicknefs by letting a drop (of a known weight) of fpirit of turpentine fpread on the furface of water. As it flowly enlarged in furface, it decreafed in thicknefs, and produced, in regular order, feveral of the more compounded colours of the Newtonian feries. But before it came to the 20th ring from the centre, it became very irregular and fpotty.

60
Contact is not proved in collifion.

The inference to be drawn from this combination of the two optical facts is remarkable and important. It is, that we have no authority for affirming that the changes of motion by the collifion of bodies is brought about by abfolute contact in any inftance whatever. The glaffes are not in contact where there is vivid reflection: and we have no proof that they are in contact in the black fpot, however great the compreffion may be.

61
Therefore impulfion cannot explain gravitation;

It is hardly neceffary now to fay, that all attempts to explain gravitation, or magnetifm, or electricity, or any fuch apparent action at a diftance by the impulfions of an unfeen fluid, are futile in the greateft degree. Impulfion, by abfolute contact, is fo far from being a familiar phenomenon, that it may juftly be queftioned whether we have ever obferved a fingle inftance of it. The

Impulsion.

The supposition of an invisible impelling fluid is not more gratuitous than it is useless; because we have no proof that a particle of this fluid does or can come into contact with the body which we suppose impelled by it, and therefore it can give no explanation of an action that is apparently *e distanti*.

62
But impulsion may be explained by continued pressure.

The general inference from the whole seems to be, that, instead of explaining pressure by impulse, we must not only derive all impulse from pressure, but must also ascribe all pressure to action from a distance; that is, to properties of matter by which its particles are moved without geometrical contact.

This collection of facts conspires, with many appearances of fluid and solid bodies, to prove that even the particles of solid, or sensibly continuous bodies, are not in contact, but are held in their respective situations by the balance of forces which we are accustomed to call attractions and repulsions. The fluidity of water under very strong compressions (which have been known to compress it $\frac{1}{78}$ of its bulk), is as inconsistent with the supposition of contact as the fluidity of air is. The shrinking of a body in all its dimensions by cold, nay, even the bending of any body, cannot be conceived without allowing that *some* of its ultimate unalterable atoms change their distances from each other. The phenomena of capillary attraction are also inexplicable, without admitting that particles act on others at a distance from them. The formation of water into drops, the coalescence of oil under water into spherical drops, or into circular spots when on the surface, shew the same thing, and are inexplicable by mere adhesion. In short, all the appearances and mutual actions of tangible matter concur in shewing, that the atoms of matter are endowed with inherent forces, which cause them to approach or to avoid each other. The opinion of Boscovich seems to be well founded; namely, that at all sensible distances, the atoms of matter tend toward each other with forces inversely as the squares of the distances, and that, in the nearest approach, they avoid each other with *insuperable* force; and, in the intermediate distances, they approach or avoid each other with forces varying and alternating by every change of distance. See the article BOSCOVICH, *Suppl.*

63
Physical contact explained.

FROM all that has been said, we learn that physical or sensible contact differs from geometrical contact, in the same manner as physical solidity differs from that of the mathematician. Euclid speaks of cones and cylinders standing on the same base, and between the same parallels. These are not material solids, one of which would press the other out of its place. Physical contact is indicated, immediately and directly, by our sense of touch; that is, by exciting a pressure on our organ of touch when it is brought sufficiently near. It is also indicated by impulsion; which is the immediate effect of the pressure occasioned by a sufficient approximation of the body impelling to the body impelled. The impulsion is the completion of the same process that we described in the example of the magnets; but the extent of space and of time in which it is completed is so small that it escapes our observation, and we imagine it to be by contact and in an instant. We now see that it is similar to all other operations of accelerating or retarding forces, and that no change of velocity is instantaneous; but, as a body, in passing from one point of space to another, passes through the intermediate space; so, in changing from one velocity to another, it passes through all the intermediate degrees without the smallest *saltus*.

We thus avoid many absurdities.

And, in this way, is the whole doctrine of impulsion brought within the pale of dynamics, without the admission of any new principle of motion. It is merely the application of the general doctrines of dynamics to cases where every accelerating or retarding force is opposed by another that is equal and contrary. We have found, that the opinion, that there is inherent in a moving body a peculiar force, by which it perseveres in motion, and puts another in motion by shifting into it, is as useless as it is inconsistent with our notions of motion and of moving forces. The impelled body is moved by the insuperable repulsion exerted by all atoms of matter when brought sufficiently near. The retardation of the impelling body does not arise from an *inertia*, or resisting sluggishness of the body impelled, but because this body also repels any thing that is brought sufficiently near to it. We can have no doubt of the existence of such causes of motion. Springs, expansive fluids, cohering fibres, exhibit such active powers, without our being able to give them any other origin than the FIAT of the Almighty, or to comprehend, in any manner whatever, how they reside in the material atom. But if once we admit their existence and agency, every thing else is deduced in the most simple manner imaginable, without involving us in any thing incomprehensible, or having any consequence that is inconsistent with the appearances. Whereas both of these obstructions to knowledge come in our way, when we suppose any thing analogous to force inherent in a moving body solely because it is in motion. It forces us to use the unmeaning language of force and motion passing out of one body into another; and to speak of force and velocity as things capable of division and actual separation into parts. The force of inertia is one of the bitter fruits of this misconception of things. It is amusing to see how metaphysicians of eminence, such as D'Alembert, endeavour to make its operations tally with acknowledged principles. In his celebrated work on dynamics, the most elaborate of all his performances, he explains how a body, whose mass is 1, moving with the velocity 2, must stop another body whose mass is 2, moving with the velocity 1, in the following manner: He supposes the velocity 2 to consist of two parts, and that, in the instant of collision, one of these parts destroys the motion of one half of the other body, and then the other part destroys the motion of the other half. These are words; but in vain shall we attempt to accompany them by clear conceptions. His distinction between the force of inertia and what he calls the active forces of bodies, such as the force of bodies which strike each other in opposite directions, is equally unsusceptible of clear conceptions. Active forces (says he) absorb a part of the motion; but when inertia takes part of the motion from the striking body, this motion passes wholly into the body that is stricken, none of it being absorbed or really destroyed. He demonstrates this by the equation $A \times \overline{a-x} = B \times \overline{x-b}$, which is a mere narration of facts, but no deduction from the nature of inertia, nor even any establishment of that nature by philosophical argument. And in attempting to give still clearer notions (being sensible that some

great

great obscurity still hangs about it), he says, "Inertia therefore, and properly speaking, is the mean of communicating motion from one body to another. Every body resists motion; and it is by resisting that it receives it; and it receives precisely as much as it destroys in the body which acts on it." Surely almost every word of this sentence is doing violence to the common use of language. What can be more incomprehensible than that a body resists motion only when it receives it! Should a man be thought to resist being pushed out of his place when he actually allows another to displace him, and not to resist when he firmly keeps his place? All these difficulties and puzzling questions vanish when we give over speaking of inertia as something distinguishable from the active forces or causes of motion which we find in bodies, and distinguish by the names of elasticity, cohesion, magnetism, electricity, weight, &c. and which philosophers have classed under one name, accelerating or retarding force, according as its direction chances to be the same, or the opposite to that of the motion under consideration. To suppose it a *peculiar* faculty by which a body maintains its condition of motion or rest, is contrary to every conception that we can annex to the words faculty, power, force. It is frivolous in the extreme to say, that snow has the faculty of continuing white or cold; or that it resists being melted because it melts, or because heat must be employed to melt it.

64
Strongest argument for inertia is the composition of force with a previous motion.

The only argument that we know for giving the name force to the perseverance of matter in its state of motion (or rather for ascribing this perseverance to the exertion of a peculiar faculty), which appears to deserve any attention, is one that we do not recollect the express employment of for this purpose, namely, the composition of a previous motion with the motion which a known force would produce in the body at rest. We know, that if a body be moving eastward at the rate of four feet per second, and a force act on it which would impel it from a state of rest at the rate of three feet per second to the south, the body will move at the rate of five feet per second in the direction E. 36° 52′ S. We know also, that if a force act on this body at rest, so as to give it a motion eastward at the rate of four feet per second, and if another force act on it at the same instant, so as to give it a motion to the south at the rate of three feet per second, the body will move at the rate of five feet per second in the direction E. 36° 52′ S. In this instance, the body previously in motion seems to possess something equivalent to what is allowed to be a moving force. Why therefore refuse it the name? The answer is easy. The term force has been applied, by all parties, to whatever produces a *change* of motion, and is measured by the *change* which accompanies its exertion. There is some difference between the parties about the way of estimating this measure; but all agree in making, not the motion, but the change of motion, the basis of the measurement. Now we

Answered.

shewed, at great length, in the article Dynamics, that the *change* of motion, in every case, is that motion which, when compounded with the former motion, constitutes the new motion. Did we take the new motion itself as the characteristic and measure of the changing force, it would be different in every different previous state of the body, and would neither agree with our general notion of force, nor with the knowledge that we have of the actual pressures and other moving forces that we know. The sole reason why the previous motion is equivalent with a force is, that the only mark or knowledge that we have of a moving force is the motion which it is conceived to produce. The force is equivalent with the previous motion, because we know nothing of it but that motion; and the name that we give it, only marks some external thing to which it has an observed relation. We call it magnetism or electricity, because we observe that a magnet or an electrified body gives *occasion* to its appearance. We never observe the resistance of *inertia*, except in cases where we know, from other circumstances, that moving forces inherent in bodies are really brought into action. The inertia of the ball which has been moved by a stroke of another, is inferred from the diminution of that other's motion. But this is occasioned precisely in the same way as the diminution of the motion of the magnet A in the first example; an event which every unprepossessed person ascribes to the repulsion of B in the opposite direction, and not to its inertia.

We trust that our readers are not displeased with this detail of the procedure of Nature in the phenomena of impulsion. It has been prolix; because we apprehend, that the too synoptical manner in which the laws of collision have always been delivered, leaves the mind in great obscurity concerning the connection of the events. General facts have been taken for philosophical principles and elementary truths; whereas they were deductions from the sum total of our knowledge. They were very proper logical principles for a synthetical discussion; but their previous establishment as general facts was necessary. We have established the two most general facts from which the result of every collision may be deduced with the utmost ease. The first is, that in the instant of greatest compression, the common velocity is $= \frac{A\,a \pm B\,b}{A + B}$; and we have shewn, that this is applicable to the collision of unelastic bodies. The second is, that the change in perfectly elastic bodies is double of the change in unelastic bodies. The *conservatio momentorum*, and the *conservatio virium vivarum*, are also general facts; or rather they are the same mentioned with those above, considered in another aspect. They may all be used as the principles of a synthetic treatise of impulsion; and they have been so employed. Each has its own advantages.

Mr Maupertuis gives a treatise on the Communication of Motion, that is, of impulsion or collision, which has the appearance of being deduced from a new principle, which he calls the principle of smallest action. He supposes, that perfect wisdom will accomplish every thing by the smallest expenditure of action; and he chanced to observe, in the equations employed in the common doctrine of impulsion, a quantity which is always a minimum. He chooses to consider this as the expression of the action. 65

65
Principle of least action.

His principle or axiom, deduced from the perfect wisdom of God, is thus expressed: "When any change happens in nature, the quantity of action necessary for it is the smallest possible." And then he adds,

"In mechanical changes, the quantity of action is the product of the quantity of matter in the body by the space passed over, and by the velocity of the motion." This is evidently the measure adopted long before by

Leibnitz

Impulsion.

Leibnitz (see *Phil. Transf.* vol. xliii. p. 423, &c.), and it is equivalent to $m v^2$; because the space multiplied by the velocity is as the square of either. We refer to Dr Jurin's remarks on this passage for proof that this is by no means a just measure of action; and only observe here, that we can form no other notion of velocity than that of a certain space described in a given time. The change produced is not the actual description of a line, but the determination to that motion. It is in this respect alone that the condition of the body is changed; and therefore the product $m v$, and not $m s v$, is the proper measure of the action. On the authority of this maxim of divine conduct, Maupertuis investigates the results which will make this quantity a minimum, and asserts that these *must* be the laws of collision. Luckily this investigation is extremely simple, and very neat and perspicuous; and it gives very easy solutions. For example, the unelastic body A, moving with the velocity a, overtakes the unelastic body B, moving with the velocity b. Both move after the collision with the velocity x. This velocity is required. To determine this, we must make $A \times \overline{a-x}|^2 + B \times \overline{x-b}|^2$ a minimum: or $A a^2 - 2 A a x + A x^2 + B x^2 - 2 B b x + B b^2$ is a minimum. Therefore $-2 A a \dot{x} + 2 A x \dot{x} + 2 B x \dot{x} - 2 B b \dot{x} = 0$, or $2 A a + 2 B b = 2 A x + 2 B x$, and $x = \frac{A a + B b}{A + B}$; as we have already shewn it to be.

The amiable and worthy author grew more fond of his theory, when he saw what he imagined to be its influence extended to an immense variety of the operations of nature. Euler demonstrated, that the quantity called *action* by Maupertuis was a minimum in the planetary motions, and indeed in all curvilineal motions in free space. But all the while, this principle of least action is a mere whim, and the formula which is so generally found a minimum has no perceptible connection with the quantity of action. In many cases to which Maupertuis has applied it, the conclusions are in direct opposition to any notion that we can form of the economy of action. Nay, it is very disputable whether it does not, on the contrary, express the greatest want of economy; namely, a minimum of effect from a given expenditure of power. In the case of impulsion, this minimum is the mathematical result of the equality and opposition of action and reaction. Maupertuis might have pleased his fancy by saying, that it became the infinite wisdom of God to make every primary atom of matter alike; and this would have answered all his purpose.

66 Enquiry into the distribution of impulse from the point that is struck.

There still remains to be considered a very material circumstance in the doctrine of impulsion, which produces certain modifications of the motions that are of mighty practical importance. We have contented ourselves with merely stating the moving force that is brought into action in the points of physical contact; but have not explained how this produces the progressive motion of every particle of the impelled body, and what motion it really does produce in the remote particles. A body, besides the general progressive motion which it receives from the blow, is commonly observed to acquire also a motion of rotation, by which it whirls round an axis. It has not been shewn, that when a body has received an impulse by a blow in a particular direction on one point, it will proceed in that direction, or in what direction it will proceed. Experience shews us, that this depends on circumstances not yet considered. The billiard player knows, that by a stroke in one direction he can make his antagonist's ball move in a direction extremely different.

These are questions of great intricacy and difficulty, and would employ volumes to treat them properly. We have already enlarged this article till we fear that we have exhausted the reader's patience, and deviated from the proportion of room justly allowable to IMPULSION. We must therefore limit our attention to such things only as seem elementary, and indispensably necessary for a useful application of the doctrine of impulsion.

With respect to the *direction* of the motion produced by impulsion, the very example just now borrowed from billiard playing, shews that it is important, and by no means obvious. We are sorry to say, that we have nothing to offer in solution of this question that will be received by all as demonstration. It is comprehended in the following proposition, which we bring forward merely as a matter of fact.

67 Action of bodies by contact is perpendicular to the touching surface.

The direction of the stroke or pressure exerted by two bodies in physical contact, is always perpendicular to the touching surfaces. Of this truth we have a very distinct and pretty example and proof by the billiard table. If two balls A and B (fig. 2.) are laid on the table in contact, and A is smartly struck by a third ball C in any direction C c, so that the line a A, which joins the point of contact a with the centre A, may make an obtuse angle with the line A B, joining the centres of the two balls, the ball B will always fly off in the direction ABF. The pressure on B, which produces the impulsion, is evidently exerted at the point b of contact, and the direction BF is perpendicular to the plane G b H, touching both balls in the point b. The primary stroke is at a, and acts in the direction a A, although C moved in the direction C c. Had A been alone, it would have gone off in the direction a A produced. But the force acting in the direction a A is equivalent to the two forces $a d$ and d A, of which d A presses the ball on B at b, and produces the motion. In like manner, another ball E, so laid that b B e is obtuse, will fly off in the direction ED, which may even be opposite to C c. These are matters of fact; not indeed precisely so, because billiard balls are not perfectly elastic, restoring their figure with a promptitude equal to that of their compression; and also because there is a little friction, by which the point a of the ball A is dragged a little in the direction of C's motion. This may both give a twirl to A, and diminish its pressure on B. The general result, however, is abundantly agreeable to the doctrines now delivered. But we wish to shew on what properties of tangible matter this depends; and although we dare not hope for implicit belief, we expect some credit in what we shall offer.

Demonstration.

We have evident proof, that at a distance which is not unmeasurable by its minuteness, and certainly far exceeds the 900th part of an inch, bodies repel each other with very great force. This distance also far exceeds the distance between the particles, if these are discrete. Let $m n$ (fig. 3.) be the distance at which a particle repels another, and let P be a particle situated at at a lefs diftance than mn from the furface AC of a folid body. With a radius PA, equal to mn, defcribe a fegment of a fphere ABC, and draw PB perpendicular to AC. It is plain, that every particle of matter in the fegment ABC repels the particle P, and that it is not affected by any more. Let D be any fuch particle. It repels P in the direction DP. But there is another particle d fimilarly fituated on the other fide of PB. This will repel P with equal force in the direction dP. Therefore the two particles D and d will produce a joint repulfion in the direction BP. The like may be faid of every particle and its correfponding one on the other fide of PB. Therefore the joint repulfion of all the matter in the fegment will have the direction BP. It is plain, that the radius of curvature of every fenfible figure may be confidered as immenfely great in comparifon of mn; and therefore the propofition is manifeft.

This is a propofition of very great importance to the artift and the engineer, as well as to the philofopher. In all the connections of engines and machines, the mutual action is regulated by this fact. The mutual preffure at the contacts of the teeth of wheels and pinions depend fo much on it, that it is eafy to make them of fuch a fhape that they fhall produce no force whatever that is of any fervice; and it requires a fkilled attention to their forms to obtain the fervice we want. This will be confidered with fome care in the article MACHINE.

Having thus difcovered the *direction* of the real impulfion, and that it may be very different from that of the force exerted, we proceed to confider what will be the direction and velocity of the motion, and whether it will be accompanied with any rotation.

68
A ftroke, whofe action paffes through the centre of a pofition of folid body, impels it without rotation.

Our readers are acquainted with the elementary mechanical property of the centre of gravity. If a body be fupported at this point by a force acting vertically upwards, and equal to the united weight of every particle of matter in it, it will not only remain at reft, but will have no tendency to incline to either fide; that is, the upward force balances the weight of the whole body, and the mechanical momenta of all the heavy particles balance each other, like the weights in the fcales of a fteelyard. That this may be the cafe, we know that if the weight of every particle be multiplied into the horizontal lever by which it hangs (which is a line drawn from the particle perpendicular to a vertical plane paffing through the centre of gravity), the fum of all the products on one fide muft be equal to the fum of all the products on the other fide. Therefore, if we fuppofe the particles all equal, and reprefent each by unity, the fums of all the perpendiculars themfelves muft be equal. How is this balancing effected? Every particle tends downwards with a certain force. It muft therefore be kept up by a force *precifely* equal and oppofite. This muft be propagated to the particle by means of the connecting corpufcular forces. The force propagated to any particle is equal and oppofite to the force acting on that particle, which it balanced; and if not balanced, it would produce a motion equal and oppofite to that produced by the other force. Gravity would caufe every particle to defcend equally; therefore the force which, by acting on one point, excites thofe balancing forces on each particle, would caufe them to move equally upwards. And fince this is true in *any* attitude of the body, it follows, that a force, acting in *any* direction through the centre of gravity, will caufe all the particles to move in that direction equally; that is, without rotation.

Hence we learn, that when the direction of the ftroke given to any body paffes through the centre of gravity, the body will move in that direction without any rotation. If the quantity of matter, or number of equal particles in the body, be m, the moving power P will imprefs on each particle an accelerating force f, equal to the mth part of P. Therefore $f = \frac{P}{m}$, and $P = mf$. An accelerating force is eftimated by the velocity v, which it generates by acting uniformly during fome time t, or $v = ft$, and $f = \frac{v}{t}$, and $P = m\frac{v}{t}$, and $v = \frac{P}{m}t$. The fymbol t may be omitted, if we reckon every force by the velocity which it can produce in a fecond. Thus may all forces be compared with gravity, by taking 32 feet for the meafure of gravity. Then mv will exprefs the number of pounds which give a preffure equal to the force under confideration. Thus if the force can generate the velocity 48 feet per fecond in 100 pounds of matter, by acting on it uniformly during a fecond, its preffure is equal to the weight of 150 pounds.

This is direct impulfion.

When a body A, moving with the velocity a, overtakes or meets a body B, moving with the velocity b, and the line perpendicular to their touching furfaces paffes through the centres of both in the direction of their motion, all the circumftances of the collifion are determined by the rules already laid down. This is called DIRECT IMPULSE; and it is this which admits the application of the fimple doctrines of impulfion, deduced, as we have done it, from the action of accelerating forces. All that was faid of the changes of motion produced in the magnets obtain here without any farther modification.

We may juft be allowed to take notice of a curious obfervation of Mr Huyghens on the collifion of perfectly elaftic bodies. Inftead of impelling the elaftic ball C by the ftroke of the elaftic ball A, we may caufe A to ftrike an intermediate ball B (alfo perfectly elaftic), which is lying in contact with C. In many cafes, the ball B will not ftir fenfibly from its place, and C alone will fly off. Nay, if a long row of equal billiard balls lie in contact, and one of the extreme balls be hit by another ball in the direction of the row, only the remote ball of the row will fly off. All this is eafily feen and underftood, by confidering them as bodies mutually repelling, and placed at the limits of their mutual action. Or even fuppofing them elaftic balls, at a very fmall diftance from each other: The ball employed to ftrike the firft comes to reft, and the ftricken ball moves off with its velocity: It ftrikes the fecond ball of the row, and is brought to reft: The fecond ftrikes the third, and is brought to reft: And this goes on in fucceffion to the laft, which is the only one that can fly off. The curious obfervation of Mr Huyghens is, that a greater velocity will be communicated by a large ball to a fmall one, if we employ the intermediation of another ball of a fize between the two; and that the velocity will be the greateft poffible when the interme-

 diate

Impulsion. diate ball is a mean proportional (geometrical) between the two. This is also easily deduced from the similar attention to the action of the accelerating forces, or from the supposition of successive impulses. From this it also follows, that a greater velocity will be produced by the intervention of two, three, or more, mean proportionals.

69 Oblique Impulsion. But the direction of the stroke may not be the same with that of the motion. This is called OBLIQUE IMPULSE. The cases of oblique collisions are extremely different, according to the directions of the motions; and the results are, in many of them, far from being obvious. But we have not room for a particular treatment of them. We shall therefore avail ourselves of some of the general facts mentioned above, by means of which we may reduce all the varieties to some easy cases. The most serviceable general facts are: 1. That the actions of bodies on each other depend on their relative motions; and, 2. That the motion of the common centre is not changed by the collision. These enable us to reduce all to the case of a body in motion striking another at rest. We have only to determine their relative motion by the proposition in DYNAMICS, n° 67. and then to superadd the common motion, which changes the relative into the true motions. Thus, if two bodies A and B (fig. 4.) meet in D, describing the lines AD, BD, the collision is the same as if B had remained at rest, and A had come against it with the motion AB. In the mean time, the common centre of position has described CD. If the bodies are unelastic, they remain united, and proceed in the line CD produced toward E, and their common velocity will be represented by DE equal to CD, if AD and BD represented their initial velocities. If the bodies are elastic, they separate again, and they separate from the common centre in the opposite direction, and with the same velocities with which they approached it. Therefore draw *a* E*b* parallel to ACB, and make E *a*, E *b* equal to CA and CB, and then D *a* and D *b* are the paths and velocities of the bodies. All this is abundantly plain, and is a necessary deduction from the general principle, that the motion of the centre is not affected by any equal and opposite forces which connect the bodies of a system.

70 Often accompanied by rotation. But this great simplicity is not sufficient for ascertaining the results of collision which occur in many of the most important cases. It not only supposes that AD and ED are exactly proportional to the velocities of A and B, but also that they meet, so that the plane of mutual contact is perpendicular to the line AB, and that the stroke on each is directed to its centre. These circumstances will not always be combined, even in the case of spherical bodies. The consequence will be, that although the motion of the centre remains the same, that of the bodies may sometimes be different. We must therefore give a general proposition, which will, with a little trouble, enable the reader to determine all the motions which can take place, whether progressive or rotative.

71 General theorem. Let the body A (fig. 5.), moving with the velocity V, in the direction AD, strike the body B at rest. Let F be the point of mutual contact, and *b* FH a plane touching both bodies in F. Draw AFP perpendicular to this tangent plane, and through G, the centre of position of B, draw PGC perpendicular to FP, and GI parallel to FP. Let C, in the line PG, be the spontaneous centre of conversion (ROTATION, *Encycl.* n° 77, &c.), corresponding to the point of percussion F. Join CF. Let the direction cut the tangent plane in H, and PF in A; and let AH represent the velocity V.

The impulse is made at the point F, in the direction AF or FP, and the centre of position of the body B will advance in the direction GI parallel to FP, the direction of the effective impulse. But, because this does not pass through the centre G, the body will advance, and will also turn round an axis passing through G, perpendicular to the plane of the lines GP, PF, and the spontaneous axis of conversion will pass through some point C of the line PG, and will also be perpendicular to the same plane. All this has been demonstrated in the article ROTATION, n° 94, &c. Complete the parallelogram AFHE. It is plain, that the motion AH is equivalent to AE and AF. By the motion AE, A only slides along the surface of B, without pressing it, or causing any tendency to motion in that direction, except perhaps a little arising from friction. It is by the motion AF alone that the impulse is made.

Therefore let v be $= V \times \frac{AF}{AH}$; and then $A \times v$ may be called the *efficient impulse* of the body A in the present circumstances, and v the *efficient velocity*. This will be diminished by the collision. Let x be the unknown velocity remaining in A after the collision, or rather in the instant of the greatest compression and common motion of the touching points of A and B, estimated in the direction FP. The effective momentum lost by A must therefore be $A \times \overline{v-x}$: but the same must be gained by B, and its centre G must move in the direction GI, parallel to FP, with this momentum; and therefore with the velocity $\frac{A \times \overline{v-x}}{B}$. That this may be the case, the point of percussion F must yield with the velocity x, because the bodies are in contact. But because C is the spontaneous axis of conversion, every particle is *beginning* to describe an arch of a circle round this axis. Therefore F is beginning to move in the direction F*g*, perpendicular to the momentary radius vector CF. Let F*g* be a very minute arch, described in a moment of time. Draw *gf* perpendicular to FP. Then F*f* is the motion F*g* reduced to the direction FP, and will express the yielding of B in the direction of the impulse, while G describes a space equal to $\frac{A \times \overline{v-x}}{B}$, and A describes a space x. Therefore F*g* will express x. Let P*p* be the space described in the same time that F*g* is described. Draw *p*C, cutting GK in the point I. GI is the yielding of the body B to the impulse, and must therefore be equal to $\frac{A \times \overline{v-x}}{B}$.

72 Efficient velocity.

The triangles F*fg* and CPF are similar; for the angle CFP is the complement of *f*F*g* to a right angle: It is also the complement of PCF to a right angle. Therefore F*g* : F*f* = FC : CP. But F*g* : P*p* = FC : CP; because the little arches F*g*, P*p* have the same angle at C. Therefore P*p* = F*f*, = x. It is plain, that CG : CP = GI : P*p*. Therefore CG : CP =

Fig. 1.

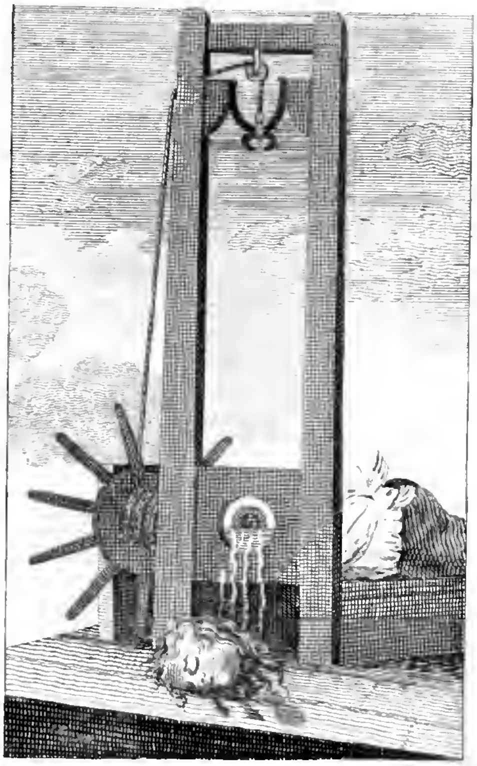

Fig. 2.

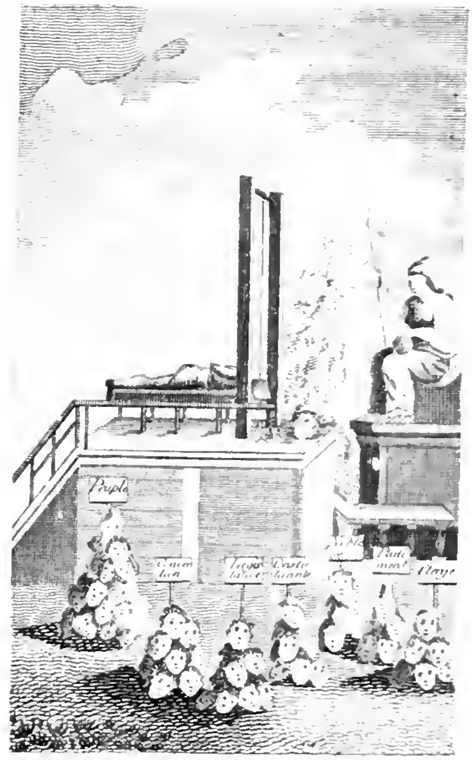

IMPULSION

Fig. 1.

Fig. 2.

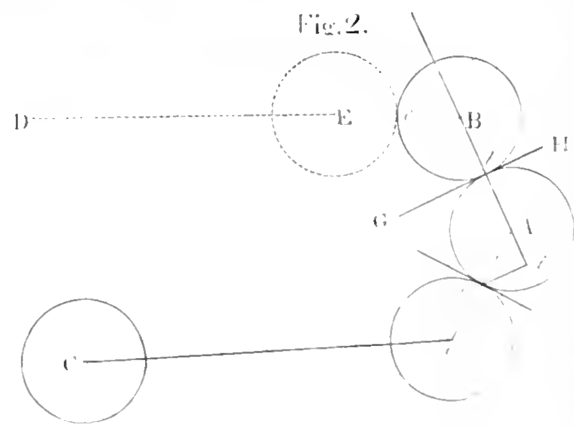

Fig. 3.

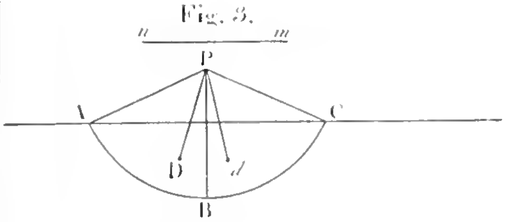

Fig. 5.

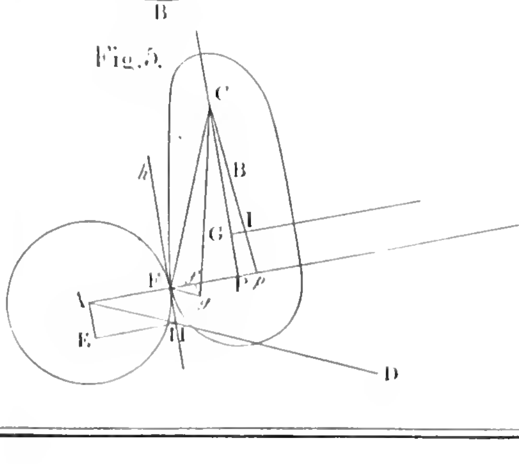

Fig. 4.

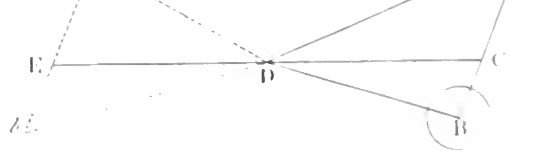

Impulsion.

$= \frac{A\times\overline{v-x}}{B} : x$, and $x = \frac{A\times\overline{v-x}\times CP}{B\times CG}$, or $x = v\times\frac{A\times CP}{B\times CG} - x\times\frac{A\times CP}{B\times CG}$; wherefore $x \times B\times CG + x\times A\times CP = v\times A\times CP$, and $x\times\overline{B\times CG + A\times CP} = v\times A\times CP$, and $x = v\times\frac{A\times CP}{B\times CG + A\times CP}$, = the velocity remaining in A, estimated in the direction FP.

73 Unelastic bodies may separate.

And u, the velocity with which G will advance, is $x\frac{CG}{CP}$; for CP : CG = Pp : GI, = $x : u$. It is evident that A will change its direction by the collision: For in the instant of greatest compression it was reacted on by a force $= A\times\overline{v-x}$ in the direction FA. This must be compounded with $A\times V$, in the direction AH, in order to obtain the new motion of A; or it may be found by compounding x, which is retained by A, with FH, which has suffered no change by the collision. The bodies will therefore separate, although they be unelastic: If they are elastic, we must double these changes on each. If B was also in motion before the collision, the motion of A must be resolved into two, one of which is equal and parallel to the motion of B: the other must be employed as we have employed the motion AH.

Expressions still more general may be obtained for x and u; namely, by taking the formulæ for the centres of conversion and percussion (Rotation, n° 96, 99.)

$$CG = \frac{\int p\,r^2}{B\times GP},\ \text{and}\ CP = \frac{\int p\,r^2 + B\times CP^2}{B\times GP},$$

where p stands for a particle of matter, and r for its distance from an axis passing through G perpendicularly to the plane of the lines GP and PF. In this way we obtain $x = v\,\frac{A\cdot\int p\,r^2 + A\cdot B\cdot GP^2}{A+B\cdot\int p\,r^2 + A\cdot B\cdot GP^2}$.

74 Change of progressive motion greatest when the direction of the effective stroke passes thro' the centres.

It is plain, from this proposition, that the progressive motion of the body depends, not only on the momentum of the impelling body, but also on the place where the other stroke is: For even although the original momentum of A be the same, and the obliquity of the stroke making v the same, and the body (and consequently $\int p\,r^2$) also remain the same, we see that x and u depend on the ratio of CP to CG. Now C and P are always on opposite sides of G: Consequently, by removing the direction FP of the impulsion farther from G, we diminish CG and increase CP; and therefore increase the value of $x = v\,\frac{A\cdot CP}{B\cdot CG + A\cdot CP}$; and consequently diminish the value of $A\times\overline{v-x}$, to which $B\times u$ is equal. The greatest momentum of B is produced when the direction of the impulse passes through G, and no rotation is produced. Indeed we are led, by a sort of common sense, to expect this.

75 Importance of this theory to seamanship, &c.

This investigation is by no means a piece of mere speculative curiosity. It is the solution of the greatest problem in practical mechanics. It is in this way that we must proceed in computing the actions of the wind and water on the sails and hull of a ship. Were it not that many circumstances concur in determining several of the preparatory steps, it is evident that the task must be almost impracticable. But the pressure and its direction are generally determined by experiment, without the trouble of computation; and we are seldom solicitous about the subsequent motion of the wind or water.

76 Impulsion on bodies confined to particular paths.

There is another question in impulsion which is of the first practical importance—namely, when the impulse is exerted on the parts of a machine, where the body struck is not at liberty to yield freely to the stroke, but must slide along some solid path, or turn round some axis, or take some other constrained motion. The operations of most engines depend on this. The operation of wedges, axes, and many cutting and piercing instruments, and the penetration of piles, impelled by a rammer, are all ascertained by the same doctrines. But the particular applications can scarcely be elucidated by any classification that occurs to us, the circumstances of the case making such great difference in the result, both in kind and degree. For example, in the simplest case that occurs, the driving of piles, the penetration of the pile depends, in the first place, on the momentum of the rammer. If the mass of the pile be neglected, the penetration through a uniformly resisting substance will be as the square of the velocity of the rammer, (Dynamics, *Suppl.* n° 95), and its absolute quantity may be determined from a knowledge of the proportion of the weight of the rammer to the resistance of the earth. But when we consider that we have to put in motion the whole matter of the pile, we learn that a great diminution of the effect must take place. We still can compute what this must be, because we have the same momentum, with a velocity diminished in a certain proportion of the sum of the matter in the rammer and pile, to that in the rammer alone.—Another defalcation arises from friction, which continually increases as the pile goes deeper;—and a still greater defalcation proceeds from the nature of the pile. If it is a piece of very dry straight grained fir, it is very elastic, and acquires almost a double velocity from the stroke of a rammer of cast iron. If it is moist and soft, especially if it is oak, or other timber of an undulated fibre, it does not acquire so great velocity, and the penetration is very much diminished. It is probable that a pile, headed with moist cork, could not be driven at all. The writer of this article found a remarkable effect of the elasticity in the process of boring limestone. When the boring bit was made entirely of steel, and tempered through its whole length to a hard spring temper, the workman bored three inches, in the same time that another bored two inches with a bit made of soft iron; and he would never use any but steel bits, if they could be hindered from chipping by the hammer (which must also be of tempered steel throughout). This has hitherto baffled many attempts. A pretty large round head, like a marlin spike, has succeeded best: but even this cracks after some days use. The improvement is richly worth attention; for the workman is delighted by feeling the hammer rise in his hand after every stroke, and says that the work is not so hard by half. *N. B.* The stone cutters at Lisbon and Oporto use iron mallets.

Impulsion on machines.

The case of impulsion made on part of a machine moveable round an axis has been considered in the article Rotation, *Encycl.* n° 72; where x is shewn to be be $= v \times \frac{A.CP^2}{\int p r^2 + A.CP^2}$. But, in this formula, r denotes the distance of p from the point C, and not from G. $\int p r^2$ in this formula, is B. CG. CP; whereas, in the formula for a free body, where r is the distance of a particle from G, $\int p r^2$ is $=$ B. CG. GP.

In the practical consideration of this question, the reader will do well to consider the whole of that article with attention. Many circumstances occur, which make a proper choice of the point of impulse, and the direction of the tangent plane, of the greatest consequence to the good performance of the machine; and there is nothing in which the scientific knowledge of the engineer is of more essential service to him. An engineer of great practice, and a sagacious combining mind, collects his general observations, and stores them up as rules of future practice. But it is seldom that he possesses them with that distinctness and confidence that can enable him to communicate his knowledge to others, or even secure himself against all mistakes; whereas a moderate acquaintance with these *elements* of real mechanics, may be applied with safety on all occasions, because arithmetical computations, when rightly made, afford the most certain of all results.

78 Great loss of power by the yielding and bending of the material.

There is a circumstance which greatly affects the performance of machines which are actuated by impulses, namely, the yielding and bending of the parts. When the moving power acts by repeated small impulsions, it may sometimes be entirely consumed, without producing any effect whatever at the remote working point of the machine; and the engineer, who founds his constructions on the elementary theories to be had in most treatises of mechanics, will often be miserably disappointed. In the usual theories, even as delivered by writers of eminence, it is asserted, that the smallest impulse will start the greatest weight. But since impulse is only a continued pressure, and requires time for the transmission of its effect through the parts of a yielding solid, it is plain that the motion of the impelling body may be extinguished before it has produced compression enough for exciting the forces which are to raise the remote parts of a heavy body from the ground. What blow with a hammer could start a feather bed? Much oftener may we expect, that a blow, given to one arm of a long lever, will be consumed in bending the whole of its length, so as to bring the remote end into action. Therefore great stiffness, and perfect elasticity, both in the moving parts and in the points of support, are necessary for transmitting the full, or even a considerable part, of the power of the impelling body. Perhaps not the half of the blow given by the wipers of a great forge or tilting mill to the shank of the hammer is transmitted in the *proper* instant of time to the hammer-head. The hammer, while it is tossed up by the blow, is quivering as it flies. Should it reach the spring above it in the time of its downward vibration, it will not be returned with such force as if it had hit the spring a moment before or after. A quarter of an inch will produce a great effect in such cases. It is found, that the minute impulses given to the pallets of a clock or watch lose much of their force by the imperfect elasticity of the pendulum or balance. We must therefore make all the parts which transmit the blow to the regulating mass of matter as continuous, hard, elastic, and stiff, as possible. The performance of ruby pallets is very sensibly weakened by putting oil on the face of them, especially in the detached scapements, which act partly by impulse. A wheel of hard tempered steel, working on a dry ruby pallet, excels all others. The intelligent engineer, seeing that, after all his care, much impulsion is unavoidably lost, will avoid employing a first mover which acts in a subsultory manner, and will substitute one of continued pressure when it is in his power. This is one chief cause of the great superiority of overshot water-wheels above the undershot.

We can now understand how it happens that Galileo, Mersennus, and others, could compare the impulse given by a falling body with the pressure of a weight in the opposite scale of a balance, and can see the reason of the immense differences, yet accompanied by a sort of regularity, in the results of the experiments. Galileo, Mersennus, and Riccioli, found them to be proofs that the forces of moving bodies are as their velocities; because the heights from which the body fell were as the squares of the weights started from the ground. Gravesande found the same thing as long as he held the same opinion; but when he adopted the Leibnitzian measure, he found many faults in the apparatus employed in his former illustrations, and altered it, till he obtained results agreeable to his new creed. But any one who examines with attention all that passes in the bending of the apparatus, and takes into account the mass of matter which must be displaced before the opposite arm rises so far as to detach the spring which gives indication of the magnitude of the stroke, must see that the agreement is purely accidental, and may be procured for any theory we please (see *Gravesande's Nat. Phil.* translated by Desaguliers, vol. i. p. 241. &c.). The proposition, n° 95, Dynamics, suffices for explaining every thing that can happen in such experiments. And it will shew us, that although the motion of impulsion is produced by pressure alone, yet impulse is incomparable with mere pressure: It is not infinitely greater, but disparate. A weight (which is a pressure) bends a spring to a certain degree, and will derange to a certain degree the fibres of a body on which it presses, before it be balanced. The same weight, falling on this spring from the *smallest* height, will bend it farther, and may crush or shiver to pieces the body which would have carried it for ever. We shall make some further remarks on this subject, of great practical importance, under the word Percussion.

The method which we have pursued in considering the doctrines of impulsion, differs considerably from that which has generally been followed; but we trust that it will not be found the less instructive. Although the reader should not adopt our decided opinion, that we have no proof of pure impulsion ever being observed, and that all the phenomena which go by that name are really the effects of pressures, analogous to gravity, he perceives that our opinion does not lead to any general laws of impulsion that are different from those which are acknowledged by all. We differ only, by exhibiting the internal procedure by which they are *unquestionably* produced in a vast number of cases, and which takes place in all that we have seen, in some degree. Our method has undoubtedly this advantage, 79 Conclusion.

vantage, that it requires no principle but one, namely, that accelerating forces are to be estimated by the acceleration which they produce. Even this may be considered, not as a principle, but merely as a definition—We get rid of all the obscurity and perplexity that result from the introduction of inertia, considered as a power—a power of doing nothing—and we are freed from the unphilosophical fiction (adopted by all the abettors of that doctrine, and even by many others) of conceiving the space, in which motions are performed, and bodies act, to be carried along with the bodies in it.—This furnishes, indeed, in some cases, a familiar way of conceiving the thing, by supposing the experiments to be made in a ship under sail, and by appealing to the fact, that all our experiments are made on the surface of a globe that is moving with a very great velocity. But it is an absurdity in philosophy, and, when minutely or argumentatively used, it does not free us from one complication of action; for, before we can make use of this substitution, we must demonstrate, that the actions depend on the relative motions only: And this, when demonstrated, *obliges* us to measure forces by the velocity which they produce.

As no part of mechanical philosophy has been so much debated about as impulsion, it will surely be agreeable to our readers to have a notice of the different treatises which have been published on the subject:

Galilei Opera, T. I. 957. II. 479, &c.

Jo. Wallisii Tractatus de Percussione. Oxon. 1669.

Borelli (Alphons) de Percussione.

See also M'Laurin's Fluxions, and his Account of Newton's Philosophy, for his Dissertation crowned by the Acad. des Sciences at Paris.—Also Dr Jurin's elaborate dissertations in the Phil. Trans. N° 479.—Also Gravesande's Nat. Philosophy, where there is a most laborious collection of experiments and reasonings; all of which receive a complete explanation by the 39th Prop. Princip. Newtoni I. or our n° 95. Dynamics. There are also many very acute philosophical observations in *Lambert's Gedanken über die Grundlehren des Gleichgewichts, und der Bewegung*, in the second part of his Gebrauch der Mathematik.—Also, in the works of Kaestner, Hamberger, and Busch. Muschenbroeck also treats the subject at great length, but not very judiciously. We do not know any work which treats it with such perspicuous brevity as M'Laurin's Account of Newton's Philosophy.

INAGUA, *Great and Little*, two small islands in the Windward Passage, N. W. of the island of St Domingo, and N. E. of the island of Cuba.—*Morse*.

INATTENDUE *Island*, (the Gower Island of Carteret) so named by Surville, lies on the north side of the islands of Arsacides, 2° 4′ east of Port Praslin.—*ib*.

INCAI, a southern branch of Amazon river, in S. America.—*ib*.

INCREMENT, is the small increase of a variable quantity. Newton, in his Treatise on Fluxions, calls these by the name *Moments*; and observes, that they are proportional to the velocity or rate of increase of the flowing or variable quantities in an indefinitely small time. He denotes them by subjoining a cypher o to the flowing quantity whose moment or increment it is; thus, xo the moment of x. In the doctrine of Increments, by Dr Brooke Taylor and Mr Emerson, they are denoted by points below the variable quantities; as $\underset{.}{x}$. Some have also denoted them by accents underneath the letter, as $\underset{,}{x}$; but it is now more usual to express them by accents over the same letter; as x'.

Method of INCREMENTS, a branch of Analytics, in which a calculus is founded on the properties of the successive values of variable quantities, and their differences or increments.

The inventor of the method of increments was the learned Dr Taylor, who, in the year 1715, published a treatise upon it; and afterwards gave some farther account and explication of it in the Philos. Trans. as applied to the finding of the sums of series. And another ingenious and easy treatise on the same, was published by Mr Emerson, in the year 1763. The method is nearly allied to Newton's Doctrine of Fluxions, and arises out of it. Also the Differential method of Mr Stirling, which he applies to the summation and interpolation of series, is of the same nature as the method of increments, but not so general and extensive.

INDEPENDENCE, MOUNT, is situated on the strait through which the waters of Lake George and East Bay flow into Lake Champlain, in the N. W. part of the town of Orwell in Rutland county, Vermont, and opposite to Ticonderoga.—*Morse*.

INDETERMINATE Problem. See Algebra, Part I. Chap. VI. *Encycl.*

Diophantus was the first writer on indeterminate problems, which, after the publication of his work in 1621 by Bachet, employed much of the time of the most celebrated mathematicians in Europe. Afterwards such problems were neglected as useless, till the public attention was again drawn to them by Euler and la Grange. The example of such men was followed by Mr John Leslie, a very eminent and self-taught mathematician; who, in the second vol. of the Transactions of the Royal Society of Edinburgh, has published an ingenious paper on indeterminate problems, resolving them by a new and general principle. "The doctrine of indeterminate equations (says Mr Leslie) has been seldom treated in a form equally systematic with the other parts of algebra. The solutions commonly given are devoid of uniformity, and often require a variety of assumptions. The object of this paper is to resolve the complicated expressions which we obtain in the solution of indeterminate problems, into simple equations, and to do so, without framing a number of assumptions, by help of a single principle, which, though extremely ſimple, admits of a very extenſive application.

"Let $A \times B$ be any compound quantity equal to another, $C \times D$, and let m be any rational number aſſumed at pleaſure; it is manifeſt that, taking equimultiples, $A \times m B = C \times m D$. If, therefore, we ſuppoſe that $A = mD$, it muſt follow that $mB = C$, or $B = \frac{C}{m}$. Thus two equations of a lower dimenſion are obtained. If theſe be capable of farther decompoſition, we may aſſume the multiples n and p, and form four equations ſtill more ſimple. By the repeated application of this principle, an higher equation, admitting of diviſors, will be reſolved into thoſe of the firſt order, the number of which will be one greater than that of the multiples aſſumed."

For example, reſuming the problem at firſt given, viz. to find two rational numbers, the difference of the ſquares of which ſhall be a given number. Let the given number be the product of a and b; then by hypotheſis, $x^2 - y^2 = ab$; but theſe compound quantities admit of an eaſy reſolution, for $\overline{x + y} \times \overline{x - y} = a \times b$. If, therefore, we ſuppoſe $x + y = ma$, we ſhall obtain $x - y = \frac{b}{m}$; where m is arbitrary, and if rational, x and y muſt alſo be rational. Hence the reſolution of theſe two equations gives the values of x and y, the numbers ſought, in terms of m; viz.

$$x = \frac{m^2a + b}{2m}, \text{ and } y = \frac{m^2a - b}{2m}.$$

INDIAN OLD TOWN, a town in Lincoln county, in the Diſtrict of Maine, ſituated on an iſland in Penobſcot river, juſt above the Great Falls, and about 60 below the Forks. Here are about 100 families, who are Roman Catholics, the remains of the Penobſcot tribe, and the only Indians who reſide in the Diſtrict of Maine. They live together in a regular ſociety, and are increaſing in number; the Sachems having laid an injunction on the young people to marry early. In a former war, this tribe had their lands taken from them; but at the commencement of the American revolution, the Provincial Congreſs granted them a tract of land, 12 miles wide, interſected in the middle by the river. They have a right, in preference to any other tribe, to hunt and fiſh as far as the mouth of the bay of Penobſcot extends. In their town is a decent church with a bell; and a prieſt reſides among them to adminiſter the ordinances.—*Morſe.*

INDIAN ORCHARD, a tract of land in Northampton county, Pennſylvania, on the W. ſide of Delaware river, on the river Lexawacſein.—*ib.*

INDIANA, a territory in Virginia, lying between Ohio river and the Laurel Mountain, containing about $3\frac{1}{2}$ millions of acres It is nearly of a triangular form, and extends in length from the Pennſylvania line to the waters of the Little Kanhaway. It was granted to Samuel Wharton, William Trent, and George Morgan, eſquires, and a few other perſons, in the year 1768, by the Shawaneſe, Delaware and Huron tribes of Indians, as a compenſation for loſſes to the amount of £85,916 : 10 : 8 currency, which theſe people had ſuſtained by the depredations of the Indians, in the year 1763. It is a valuable tract of land; but the title of the proprietors, though pronounced good by a Committee of Congreſs in 1782, is at preſent embarraſſed in conſequence of the revolution.—*ib.*

INDIAN RIVER, or *Cypreſs Swamp*, lies partly in the States of Maryland and Delaware. This moraſs extends 6 miles from eaſt to weſt, and nearly 12 from north to ſouth, including an area of nearly 50,000 acres of land. The whole of this ſwamp is a high and level baſon, very wet, though undoubtedly the higheſt land on that part of the coaſt. Falſe Cape, at the mouth of Indian river, and the N. E. part of Cedar Neck is in 38° 35′ 15″ N. lat and $11\frac{1}{4}$ miles ſouth of the lighthouſe at Cape Henlopen. Cedar Swamp contains a great variety of plants, trees, wild beaſts, birds, and reptiles.—*ib.*

INDIAN RIVER, on the eaſt coaſt of the peninſula of E. Florida, riſes a ſhort diſtance from the ſea-coaſt, and runs from north to ſouth, forming a kind of inland paſſage for many miles along the coaſt. It is alſo called Rio Ays, and has on the north ſide of its mouth the point El Palmar, on the ſouth that of the Leech. N. lat. 27° 30′, W. long. 80° 40′.—*ib.*

INDIANS. The amount of Indian population, in America, can only be gueſſed at. The new diſcovered iſlands in the South Sea, and part of the N. W. coaſt are probably the moſt populous. The beſt informed have conjectured the number of aboriginal inhabitants, or Indians, in America, to be under two millions and a half. The decreaſe ſince the diſcovery of America, has been amazing: At that period, the iſland of Hiſpaniola alone contained at leaſt a million of inhabitants; Bartholomew de las Caſas eſtimated the number at three millions. Millions were buried in the mines or hunted to death by the Spaniards, both on the iſlands and continent. In the northern parts of America, numbers were doubtleſs deſtroyed in forming the Engliſh, Dutch, and French colonies; but notwithſtanding the ruptures between the coloniſts and the Indians, very few comparatively periſhed by war. Famine, and its companion the peſtilence, frequently deſtroy whole tribes. The diſeaſes alſo introduced by the Europeans, have made great havock; the ſpirituous liquors in the uſe of which they have been initiated by the whites, prove perhaps moſt of all repugnant to population. They wane as the Europeans advance; they moulder away, and diſappear. The moſt numerous tribes are at the greateſt diſtance from the ſettlements of the whites, and it is very certain that in proportion to their diſtance they are unacquainted with the uſe of fire-arms. All the nations north of lake Superior, and thoſe beyond the Miſſiſſippi, uſe only bows and arrows, ſo that when their ſcattered ſituation is conſidered, the various cuſtoms and ſuperſtitions which it would be neceſſary to reconcile, in order to produce unity of action, and what a ſmall proportion of them have the apparatus, or underſtand the uſe of muſquetry, or poſſeſs reſources to enable them to carry on laſting hoſtilities againſt the power of the United States, it muſt be obvious that even partial defeats of the federal troops will haſten their ruin, notwithſtanding the wonderful dexterity and intrepidity which they exhibited in ſeveral actions with the regular troops in the late war. But this neither is nor ought to be the wiſh of the inhabitants of the United States; they ought to teach them the bleſſings of peace, and curb the exorbitant luſt of farther extent of territory.

Indians.

A liſt of Indian tribes, in Imlay's Hiſtory of Kentucky, makes the aggregate number leſs than 60,000 who inhabit the country from the gulf of Mexico on both ſides of the Miſſiſſippi, to the gulf of St Lawrence, and as far weſt as the country has been generally explored, that is, to the head water of the Miſſiſſippi, and from thence a good way up the Miſſouri, and between that river and Santa Fe. To give any account of the nations farther ſouth, far leſs in S. America, would be a taſk beyond all bounds; the chief of theſe are noticed under their reſpective names.

The population of the Indian nations in the ſouthern parts of the United States, ſomewhat different from Imlay, is, according to Mr Purcell, who reſided among them in 1780, as follows:

	Gun-men.	Total.
Muſcogees, commonly called Creeks	5,860	17,280
Chactaws	4,131	13,423
Chickaſaws	575	2,290
Cherokees	2,800	8,550
Catabaws	150	490
	13,516	42,033

The above red nations have increaſed in a ſmall degree ſince the general peace eſtabliſhed among them in 1777. The whites incorporated among them are few in number, and lead a vagabond life, going from tribe to tribe as their reſtleſs diſpoſition leads them. The increaſe of population is conſiderably checked by the quantities of adulterated and poiſonous ſpirituous liquors, and the venereal diſtemper introduced among them by the whites.

Major Gen. Anthony Wayne put an end to the deſtructive war with the Indians by a treaty of peace and friendſhip concluded at Greenville Aug. 3, 1795, which was ratified by the Preſident of the United States, Dec. 22, 1795. The Indian tribes ſigned the treaty in the following order: *Wyandots*, *Delawares*, *Shawanoes*, *Ottawas*, *Chipawas*, *Ottawa*, *Patawatames* of the river of St Joſeph, *Patawatames* of Huron, *Miamis*, *Miamis* and *Eel River*, *Eel River* tribe, *Miamis*, *Kickapoos* and *Kaſkaſkias*, *Delawares* of Sanduſky, and ſome of the *Six Nations* living at Sanduſky. Theſe Indians ceded to the United States various tracts of land from 2 to 12 miles ſquare, near the different poſts in the N. W. Territory. The United States delivered to the Indian tribes above named in goods to the value of 20,000 dollars; and agreed to deliver in goods to the value of 9,500 dollars annually, forever. The portion which each tribe is to receive will be ſeen in the account of the particular nation or tribe.

Little is yet known of the Indians in the interior parts of North-America. In 1792, Mr Stewart, ſaid to be in the employ of the Britiſh court, returned from four years travels through the hitherto unexplored regions to the weſtward. Taking his courſe weſt-ſouth-weſterly from the poſts on the lakes, he penetrated to the head of the Miſſouri, and from thence due W. to within 500 miles of the ſhores of the Pacific ocean. He joined the interior Indians in ſeveral battles againſt the ſhore Indians, all which coming ſhort of his object, the procuring a peace, ſo that he might explore the continent from ſea to ſea; after ſome ſtay, he returned nearly by the ſame route he had purſued in going out. Beyond the Miſſouri, Mr Stewart met with many powerful nations, in general hoſpitable and courteous. The Indian nations he viſited weſtward, appeared to be a poliſhed and civilized people, having towns regularly built, and being in a ſtate of ſociety not far removed from that of the Europeans, and only wanting the uſe of iron and ſteel to be perfectly ſo. They are always clad in ſkins, cut in an elegant manner, and in many reſpects preferable to the garments in uſe among the whites. Adjacent to theſe nations is a vaſt ridge of mountains, which may be called the Allegany of the weſtern parts of America, and ſerves as a barrier againſt the too frequent incurſions of the coaſt Indians, who entertain a mortal antipathy to the nations and tribes inhabiting the country eaſtward of the mountains.—*ib.*

Indian, ‖ Induction.

INDIAN-TOWN, in Maryland, a village ſituated on Indian Creek, on the S. E. bank of Choptank river, and in Dorcheſter county, 3 miles S. W. of New-Market.—*ib.*

INDIAN-TOWN, a ſmall poſt-town of N. Carolina, 10 miles from Sawyer's Ferry, and 52 from Edenton.—*ib.*

INDUCTION, in logic, is that proceſs of the underſtanding by which, from a number of *particular* truths perceived by ſimple apprehenſion, and diligently compared together, we infer another truth which is always *general* and ſometimes *univerſal*. It is perhaps needleſs to obſerve, that in the proceſs of induction the truths to be compared muſt be of the ſame kind, or relate to objects having a ſimilar nature; for the mereſt tyro in ſcience knows that phyſical truths cannot be compared with moral truths, nor the truths of pure mathematics with either.

That the method of induction is a juſt logic, has been ſufficiently evinced elſewhere (ſee LOGIC, Part III. chap. V. and PHILOSOPHY, nº 73—78. *Encycl.*), and is now indeed generally admitted. It is even admitted by Britiſh philoſophers to be the only method of reaſoning by which any progreſs can be made in the phyſical ſciences; for the laws of Nature can be diſcovered only by accurate experiments, and by carefully noting the agreements and the differences, however minute, which are thus found among the phenomena apparently ſimilar. It is not, however, commonly ſaid that *induction* is the method of reaſoning employed by the mathematicians; and the writer of this article long thought, with others, that in pure geometry the reaſoning is ſtrictly *ſyllogiſtical*. Mature reflection, however, has led him to doubt, with Doctor Reid,* the truth of the generally received opinion, to doubt even whether by categorical ſyllogiſms any thing whatever can be proved.

* Appendix to Vol. III. of Sketches of the Hiſtory of Man.

To the idolaters of Ariſtotle we are perfectly aware that this will appear an extravagant paradox; but to the votaries of truth, we do not deſpair of making it very evident, that for ſuch doubts there is ſome foundation.

We are led into this diſquiſition to counteract, in ſome degree, what we think the pernicious tendency of the philoſophy of Kant, which attempts have been lately made to introduce into this country. Of this philoſophy we ſhall endeavour to give ſomething like a diſtinct view in the proper place. It is ſufficient to obſerve here, that it reſts upon the hypotheſis, that "we are in poſſeſſion of certain notions *à priori*, which are abſolutely *independent of all experience*, although the *objects of experience* correſpond with them; and which are diſtinguiſhed by *neceſſity* and ſtrict *univerſality*." Theſe notions

and

Induction.

and univerfal notions, Kant confiders as a fet of *categories*, from which is to be deduced all fuch knowledge as deferves the name of fcience; and he talks, of courfe, or at leaft his Englifh tranflators reprefent him talking, with great contempt, of inductive reafoning, and fubftituting fyllogiftic demonftration in its ftead.

As his categories are not familiar to our readers, we fhall, in this place, examine fyllogifms connected with the categories of Ariftotle, which are at leaft more intelligible than thofe of Kant, and which, being likewife general notions, muft, in argument, be managed in the fame way. Now the fundamental axiom upon which every categorical fyllogifm refts, is the well known propofition, which affirms, that "whatever may be predicated of a whole *genus*, may be predicated of every *fpecies* and of every *individual* comprehended under that genus." This is indeed an undoubted truth; but it cannot conftitute a foundation for reafoning from the *genus* to the *fpecies* or the *individual*; becaufe we cannot poffibly know what can be predicated of the *genus* till we know what can be predicated of all the *individuals* ranged under it. Indeed it is only by afcertaining, through the medium of induction, what can be predicated, and what not, of a number of individuals, that we come to form fuch notions as thofe of *genera* and *fpecies*; and therefore, in a fyllogifm ftrictly categorical, the propofitions, which conftitute the *premifes*, and are taken for granted, are thofe alone which are capable of proof; whilft the conclufion, which the logician pretends to demonftrate, muft be evident to intuition or experience, otherwife the premifes could not be known to be true. The analyfis of a few fyllogifms will make this apparent to every reader.

Dr Wallis, who, to an intimate acquaintance with the Ariftotelian logic, added much mathematical and phyfical knowledge, gives the following fyllogifm as a perfect example of this mode of reafoning in the firft figure, to which it is known that all the other figures may be reduced:—

Omne animal eft *fenfu præditum.*
Socrates eft *animal.* Ergo
Socrates eft *fenfu præditus.*

Here the propofition to be demonftrated is, that Socrates is endowed with fenfe; and the propofitions affumed as felf-evident truths, upon which the demonftration is to be built, are, that "every animal is endowed with fenfe;" and that "Socrates is an animal." But how comes the demonftrator to know that "every animal is endowed with fenfe?" To this queftion we are not aware of any anfwer which can be given, except this, that mankind have agreed to call every being, which they perceive to be endowed with fenfe, an *animal*. Let this, then, be fuppofed the true anfwer: the next queftion to be put to the demonftrator is, How he comes to know that *Socrates* is an *animal?* If we have anfwered the former queftion properly, or, in other words, if it be effential to this genus of beings to be endowed with fenfe, it is obvious that he can know that Socrates is an *animal* only by perceiving him to be *endowed with fenfe*; and therefore, in this fyllogifm, the propofition to be proved is the very firft of the three of which the truth is perceived; and it is perceived intuitively, and not inferred from others by a procefs of reafoning.

Induction.

Though there are ten categories and five predicables, there are but two kinds of categorical propofitions, viz. Thofe in which the property or accident is predicated of the fubftance to which it belongs, and thofe in which the *genus* is predicated of the *fpecies* or *individual*. Of the former kind is the propofition pretended to be proved by the fyllogifm which we have confidered; of the latter, is that which is proved by the following:

Quicquid fenfu præditum, eft animal,
Socrates eft fenfu præditus. Ergo
Socrates eft animal.

That this is a categorical fyllogifm, legitimate in mode and figure, will be denied by no man who is not an abfolute ftranger to the very firft principles of the Ariftotelian logic; but it requires little attention indeed to perceive that it proves nothing. The impofition of names is a thing fo perfectly arbitrary, that the being, or clafs of beings, which in Latin and Englifh is called *animal*, is with equal propriety in Greek called ζωον, and in Hebrew נפש. To a native of Greece, therefore, and to an ancient Hebrew, the major propofition of this fyllogifm would have been wholly unintelligible; but had either of thofe perfons been told by a man of known veracity, and acquainted with the Latin tongue, that every thing endowed with fenfe was, by the Romans, called *animal*, he would then have underftood the propofition, admitted its truth without hefitation, and have henceforth known that Socrates and Mofes, and every thing elfe which he perceived to be endowed with fenfe, would at Rome be called *animal*. This knowledge, however, would not have refted upon demonftrative reafoning of any kind, but upon the credibility of his informer, and the intuitive evidence of his own fenfes.

It will perhaps be faid, that the two fyllogifms which we have examined are improper examples, becaufe the truth to be proved by the former is felf-evident, whilft that which is meant to be eftablifhed by the latter is merely verbal, and therefore arbitrary. But the following is liable to neither of thefe objections:

All animals are *mortal.*
Man is *an animal;* therefore
Man is *mortal.*

Here it would be proper to afk the demonftrator, upon what grounds he fo confidently pronounces all animals to be mortal? The propofition is fo far from expreffing a felf-evident truth, that, previous to the entrance of fin and death into the world, the firft man had furely no conception of mortality. He acquired the notion, however, by experience, when he faw the animals die in fucceffion around him; and when he obferved that no animal with which he was acquainted, not even his own fon, efcaped death, he would conclude that all animals, without exception, are mortal. This conclufion, however, could not be built upon fyllogiftic reafoning, nor yet upon intuition, but partly upon experience and partly on analogy. As far as his experience went, the proof, by induction, of the mortality of all animals was complete; but there are many animals in the ocean, and perhaps on the earth, which he never faw, and of whofe mortality therefore he could affirm nothing but from analogy, *i. e.* from concluding, as the conftitution of the human mind compels us to conclude,

conclude, that Nature is uniform throughout the universe, and that similar causes, whether known or unknown, will, in similar circumstances, produce, at all times, similar effects. It is to be observed of this syllogism, as of the first which we have considered, that the proposition, which it pretends to demonstrate, is one of those truths known by experience, from which, by the process of induction, we infer the major of the premises to be true; and that therefore the reasoning, if reasoning it can be called, runs in a circle.

Yet by a concatenation of syllogisms have logicians pretended that a long series of important truths may be discovered and demonstrated; and even Wallis himself seems to think, that this is the instrument by which the mathematicians have deduced, from a few postulates, accurate definitions, and undeniable axioms, all the truths of their demonstrative science. Let us try the truth of this opinion by analysing some of Euclid's demonstrations.

In the short article Principle (*Encycl.*), it has been shewn, that all our *first* truths are *particular*, and that it is by applying to them the rules of induction that we form general truths or axioms—even the axioms of pure geometry. As this science treats not of real external things, but merely of *ideas* or *conceptions*, the creatures of our minds, it is obvious, that its definitions may be perfectly accurate, the induction by which its axioms are formed complete, and therefore the axioms themselves *universal* propositions. The use of these axioms is merely to shorten the different processes of geometrical reasoning, and not, as has sometimes been absurdly supposed, to be made the *parents* or *causes* of *particular* truths. No truth, whether general or particular, can, in any sense of the word, be the cause of another truth. If it were not true that all individual figures, of whatever form, comprehending a portion of space equal to a portion comprehended by any other individual figure, whether of the same form with some of them, or of a form different from them all, are equal to one another, it would not be true that "things in *general*, which are equal to the same thing, or that magnitudes which coincide, or exactly fill the same space," are respectively equal to one another; and therefore the first and eighth of Euclid's axioms would be false. So far are these axioms, or general truths, from being the parents of particular truths, that, as conceived by us, they may, with greater propriety, be termed their *offspring*. They are indeed nothing more than general expressions, comprehending all particular truths of the same kind. When a mathematical proposition therefore is enounced, if the terms, of which it is composed, or the figures of which a certain relation is predicated, can be brought together and immediately compared, no demonstration is necessary to point out its truth or falsehood. It is indeed intuitively perceived to be either comprehended under, or contrary to some known *axiom* of the science; but it has the evidence of truth or falsehood in itself and not in *consequence* of that axiom. When the figures or symbols cannot be immediately compared together, it is then, and only then, that recourse is had to demonstration; which proceeds, not in a series of syllogisms, but by a process of ideal mensuration or induction. A figure or symbol is conceived, which may be compared with each of the principal figures or symbols, or, if that cannot be, with one of them, and then another, which may be compared with it, till through a series of well known intermediate relations, a comparison is made between the terms of the original proposition, of which the truth or falsehood is then perceived.

Thus in the 47th proposition of the first book of Euclid's Elements, the author proposes to demonstrate the equality between the square of the hypothenuse of a right angled triangle, and the sum of the squares described on the other two sides; but he does not proceed in the way of categorical syllogisms, by raising his demonstration on some universal truth relating to the *genus* of *squares*. On the contrary, he proceeds to *measure* the three squares of which he has affirmed a certain relation; but as they cannot be immediately compared together, he directs the largest of them to be divided into two parallelograms, according to a rule which he had formerly ascertained to be just; and as these parallelograms can, as little as the square of which they are the constituent parts, be compared with the squares of the other two sides of the triangle, he thinks of some intermediate figure which may be applied as a common measure to the squares and the parallelograms. Accordingly, having before found that a parallelogram, or square, is exactly double of a triangle standing on the same base and between the same parallels with it, he constructs triangles upon the same base, and between the same parallels with his parallelograms, and the squares of the sides containing the right angle of the original triangle; and finding, by a process formerly shewn to be just, that the triangles on the bases of the parallelograms are precisely equal to the triangles on the bases of the squares, he perceives at once that the two parallelograms, of which the largest square is composed, must be equal to the sum of the two lesser squares; and the truth of the proposition is demonstrated.

In the course of this demonstration, there is not so much as one truth *inferred* from another by *syllogism*, but all are perceived in succession by a series of simple apprehensions. Euclid, indeed, after finding the triangle constructed on the base of one of the parallelograms to be equal to the triangle constructed on the base of one of the squares, introduces an *axiom*, and says, "but the doubles of equals are equal to one another; *therefore* the parallelogram is equal to the square." But if from this mode of expression any man conceive the axiom or universal truth to be the *cause* of the truth more particular, or suppose that the *latter* could not be apprehended without a *previous* knowledge of the former, he is a stranger to the nature of evidence, and to the process of *generalization*, by which axioms are formed.

If we examine the problems of this ancient geometrician, we shall find that the truth of them is proved by the very same means which he makes use of to point out the truth of his theorems. Thus, the first problem of his immortal work is, "to describe an equilateral triangle on a given finite straight line;" and not only is this to be done, but the method by which it is done must be such as can be shewn to be incontrovertibly just. The sides of a triangle, however, cannot be applied to each other so as to be immediately compared; for they are conceived to be immoveable among themselves. A common measure, therefore, or something equivalent to a common measure, must be found, by which the triangle may be constructed, and the equality

Induction.

lity of its three sides afterwards evinced; and this equivalent Euclid finds in the *circle*.

By contemplating the properties of the circle, it was easy to perceive that all its *radii* must be equal to one another. He therefore directs two circles to be described from the opposite extremities of the given finite straight line, so as that it may be the radius of each of them; and from the point in which the circles intersect one another, he orders lines to be drawn to the extreme points of the given line, affirming that these three lines constitute an equilateral triangle. To convince his reader of the truth of this affirmation, he has only to put him in mind, that from the properties of the circle, the lines which he has drawn must be each equal to the given line, and of course all the three equal to one another; and this mutual equality is perceived by simple apprehension, and not inferred by syllogistic reasoning. Euclid, indeed, by introducing into the demonstration his first axiom, gives to it the form of a syllogism: but that syllogism proves nothing; for if the equality of the three sides of the triangle were not intuitively perceived in their position and the properties of the circle, the first axiom would itself be a falsehood. So true it is that categorical syllogisms have no place in geometrical reasoning; which is as strictly experimental and inductive as the reasoning employed in the various branches of physics.

But if this be so, how come the truths of pure geometry to be necessary, so that the contrary of any one of them is clearly perceived to be impossible; whilst physical truths are all contingent, so that there is not one of them of which the direct contrary may not easily be conceived?

That there is not one physical truth, of which the contrary may not be conceived, is not perhaps so certain as has generally been imagined; but admitting the fact to be as it has commonly been stated, the apparent difference between this class of truths and those of pure geometry, may be easily accounted for, without supposing that the former rests upon a kind of evidence totally different from that which supports the fabric of the latter.

The objects of pure geometry, as we have already observed, are the creatures of our own minds, which contain in them nothing concealed from our view. As the mathematician treats them merely as measurable quantities, he knows, with the utmost precision, upon what particular properties the relation affirmed to subsist between any two or more of them must absolutely depend; and he cannot possibly entertain a doubt but it will be found to have place among all quantities having the same properties, because it depends upon them, and upon them alone. His process of induction, therefore, by a series of ideal measurements, is always complete, and exhausts the subject; but in physical enquiries the case is widely different. The subjects which employ the physical enquirer are not his own ideas, and their various relations, but the properties, powers, and relations of the bodies which compose the universe; and of these bodies he knows neither the substance, internal structure, nor all the qualities: so that he can very seldom discover with certainty upon what particular property or properties the phenomena of the corporeal world, or the relations which subsist among different bodies, depend. He expects, indeed, with confidence, not inferior to that with which he admits a mathematical demonstration, that any corporeal phenomenon, which he has observed in certain circumstances, will be always observed in circumstances exactly similar; but the misfortune is, that he can very seldom be ascertained of this similarity. He does not know any one piece of matter *as it is in itself*; he cannot separate its various properties; and of course cannot attribute to any one property the effects or apparent effects which proceed exclusively from it. Indeed, the properties of bodies are so closely interwoven, that by human means they cannot be completely separated; and hence the most cautious investigator is apt to attribute to some one or two properties, an event which in reality results perhaps from many. (See PHILOSOPHY and PHYSICS, *Encycl.*). This the geometrician never does. He knows perfectly that the relation of equality which subsists between the three angles of a plain triangle and two right angles, depends not upon the size of the triangles, the matter of which they are conceived to be made, the particular place which they occupy in the universe, or upon any one circumstance whatever besides their triangularity, and the angles of their corrolets being exactly right angles; and it is upon this power of discrimination which we have in the conceptions of pure geometry, and have not in the objects of physics, that the truths of the one science are perceived to be necessary, while those of the other appear to be contingent; though the mode of demonstration is the same in both, or at least equally removed from categorical syllogisms.

Induction, || Inflammation.

INERTIA. See DYNAMICS and IMPULSION in this *Supplement*.

INFLAMMATION has been sufficiently explained in the *Encyclopædia*, and in the article CHEMISTRY in this *Supplement*; but it cannot be improper, in this place, to give an account of some remarkable

Spontaneous INFLAMMATIONS, which, as different substances are liable to them, have been, and may again be, the cause of many and great misfortunes.

The spontaneous inflammation of essential oils, and that of some fat oils, when mixed with nitrous acid, are well known to philosophers: so also is that of powdered charcoal with the same acid (lately discovered by M. Proust), and those of phosphorus, of pyrophorus, and of fulminating gold. These substances are generally to be found only in the laboratories of chemists, who are perfectly well acquainted with the precautions which it is necessary to take to prevent the unhappy accidents which may be occasioned by them.

The burning of a store-house of sails, which happened at Brest in the year 1757, was caused by the spontaneous inflammation of some oiled cloths, which, after having been painted on one side, and dried in the sun, were stowed away while yet warm; as was shewn by subsequent experiments.*

Vegetables boiled in oil or fat, and left to themselves, after having been pressed, inflame in the open air. This inflammation always takes place when the vegetables retain a certain degree of humidity; if they are first thoroughly dried, they are reduced to ashes, without the appearance of flame. We owe the observation of these facts to MM. Saladin and Carette.†

The heaps of linen rags which are thrown together in paper manufactories, the preparation of which is hastened

Inflammation.

hastened by means of fermentation, often take fire, if not carefully attended to.

The spontaneous inflammation of hay has been known for many centuries; by its means houses, barns, &c. have been often reduced to ashes. When the hay is laid up damp, the inflammation often happens; for the fermentation is then very great. This accident very seldom occurs to the first hay (according to the observation of M. de Bomare), but is much more common to the second; and if, through inattention, a piece of iron should be left in a stack of hay in fermentation, the inflammation of that stack is almost a certain consequence. Corn heaped up has also sometimes produced inflammations of this nature. Vanieri, in his *Prædium Rusticum*, says,

Quæ vero (gramina) nondum satis insolata recondens
Imprudens, subitis pariunt incendia flammis.

Dung also, under certain circumstances, inflames spontaneously.

In a paper, published in the *Repertory of Arts and Manufactures*, by the Rev. William Tooke, F. R. S. &c. we have the following remarkable instances of spontaneous inflammation. "A person of the name of Rüde, an apothecary at Bautzen, had prepared a pyrophorus from rye-bran and alum. Not long after he had made the discovery, there broke out, in the next village of Nauslitz, a great fire, which did much mischief, and was said to have been occasioned by the treating of a sick cow in the cow-house. Mr Rüde knew, that the countrymen were used to lay an application of parched rye-bran to their cattle for curing the thick neck; he knew also, that alum and rye-bran, by a proper process, yielded a pyrophorus; and now he wished to try whether parched rye-bran alone would have the same effect. Accordingly, he roasted a quantity of rye-bran by the fire, till it had acquired the colour of roasted coffee. This roasted bran he wrapped up in a linen cloth; in the space of a few minutes there arose a strong smoke through the cloth, accompanied by a smell of burning. Not long afterwards the rag grew as black as tinder, and the bran, now become hot, fell through it on the ground in little balls. Mr Rüde repeated the experiment at various times, and always with the same result. Who now will any longer doubt, that the frequency of fires in cow-houses, which in those parts are mostly wooden buildings, may not be occasioned by this common practice, of binding roasted bran about the necks of the cattle? The fire, after consuming the cattle and the shed, communicates itself to the adjoining buildings; great damage ensues; and the ignorant look for the cause in wilful and malicious firing, consequently in a capital crime."

The same author informs us, that in the spring of the year 1780, a fire was discovered on board a Russian frigate lying in the road of Cronstadt; which, if it had not been timely extinguished, would have endangered the whole fleet. After the severest scrutiny, no cause of the fire was to be found; and the matter was forced to remain without explanation, but with strong surmises of some wicked incendiary being at the bottom of it. In the month of August, in the same year, a fire broke out at the hemp-magazine at St Petersburgh, by which several hundred thousand poods‡ of hemp and flax were consumed. The walls of the magazine are of brick, the floors of stone, and the rafters and covering of iron; it stands alone on an island in the Neva, on which, as well as on board the ships lying in the Neva, no fire is permitted. In St Petersburgh, in the same year, a fire was discovered in the vaulted shop of a furrier. In these shops, which are all vaults, neither fire nor candle is allowed, and the doors of them are all of iron. At length the probable cause was found to be, that the furrier, the evening before the fire, had got a roll of new cere-cloth (much in use here for covering tables, counters, &c. being easily wiped and kept clean), and had left it in his vault, where it was found almost consumed.

‡ A pood consists of 40 pounds Russ, or 36 English.

In the night between the 20th and 21st of April 1781, a fire was seen on board the frigate Maria, which lay at anchor, with several other ships, in the road off the island of Cronstadt; the fire was, however, soon extinguished; and, by the severest examination, little or nothing could be extorted concerning the manner in which it had arisen. The garrison was threatened with a scrutiny that should cost them dear; and while they were in this cruel state of suspence, an order came from the sovereign, which quieted their minds, and gave rise to some very satisfactory experiments.

It having been found, upon juridical examination, as well as private inquiry, that in the ship's cabin, when the smoke appeared, there lay a bundle of matting, containing Russian lamp-black prepared from fir-soot, moistened with hemp-oil varnish, which was perceived to have sparks of fire in it at the time of the extinction, the Russian admiralty gave orders to make various experiments, in order to see whether a mixture of hemp-oil varnish and the forementioned Russian black, folded up in a mat and bound together, would kindle of itself.

They shook 40 pounds of fir-wood soot into a tub, and poured about 35 pounds of hemp-oil varnish upon it; this they let stand for an hour, after which they poured off the oil. The remaining mixture they now wrapped up in a mat, and the bundle was laid close to the cabin, where the midshipmen had their birth. To avoid all suspicion of treachery, two officers sealed both the mat and the door with their own seals, and stationed a watch of four sea officers, to take notice of all that passed the whole night through; and as soon as any smoke should appear, immediately to give information to the commandant of the port.

The experiment was made the 26th of April, about 11 o'clock A. M. in presence of all the officers named in the commission. Early on the following day, about six o'clock A. M. a smoke appeared, of which the chief commandant was immediately informed by an officer: he came with all possible speed, and through a small hole in the door saw the mat smoking. Without opening the door, he dispatched a messenger to the members of the commission; but as the smoke became stronger, and fire began to appear, the chief commandant found it necessary, without waiting for the members of the commission, to break the seals and open the door. No sooner was the air thus admitted, than the mat began to burn with greater force, and presently it burst into a flame.

The Russian admiralty, being now fully convinced of the self-enkindling property of this composition, transmitted their experiment to the Imperial Academy of Sciences; who appointed Mr Georgi, a very learned and able adjunct of the academy, to make farther experiments on the subject. Previous to the relation of these experiments, it is necessary to observe, that the Russian fir-black is three or four times more heavy, thick, and unctuous, than that kind of painters black which the Germans call *kien-rahm*. The former is gathered at Ochta, near St Petersburgh, at Mosco, at Archangel, and other places, in little wooden huts, from resinous fir-wood, and the unctuous bark of birch, by means of an apparatus uncommonly simple, consisting of pots without bottoms set one upon the other; and is sold very cheap. The famous fine German *kien-rahm* is called in Russia *Holland's black*. In what follows, when raw oil is spoken of, it is to be understood of linseed-oil or hemp-oil; but most commonly the latter. The varnish is made of five pounds of hemp-oil boiled with two ounces and a half of minium. For wrapping up the composition, Mr Georgi made use of coarse hemp-linen, and always single, never double. The impregnations and commixtures were made in a large wooden bowl, in which they stood open till they were wrapped up in linen.

Three pounds of Russian fir-black were slowly impregnated with five pounds of hemp-oil varnish; and when the mixture had stood open five hours, it was bound up in linen. By this process it became clotted; but some of the black remained dry. When the bundle had lain sixteen hours in a chest, it was observed to emit a very nauseous, and rather putrid, smell, not quite unlike that of boiling oil. Some parts of it became warm, and steamed much; this steam was watery, and by no means inflammable. Eighteen hours after the mixture was wrapped up, one place became brown, emitted smoke, and directly afterwards glowing fire appeared. The same thing happened in a second and a third place, though other places were scarcely warm. The fire crept slowly around, and gave a thick, grey, stinking smoke. Mr Georgi took the bundle out of the chest, and laid it on a stone pavement; when, on being exposed to the free air, there arose a slow burning flame, a span high, with a strong body of smoke. Not long afterwards there appeared, here and there, several chaps or clefts, as from a little volcano, the vapour issuing from which burst into flame. On his breaking the lump, it burst into a very violent flame, full three feet high, which soon grew less, and then went out. The smoking and glowing fire lasted for the space of six hours; and afterwards the remainder continued to glow without smoke for two hours longer. The grey earthy ashes, when cold, weighed five ounces and a half.

In another experiment, perfectly similar to the foregoing, as far as relates to the composition and quantities, the enkindling did not ensue till 41 hours after the impregnation: the heat kept increasing for three hours, and then the accension followed. It is worthy of remark, that these experiments succeeded better on bright days than on such as were rainy; and the accension came on more rapidly.

In another experiment, three pounds of Russian fir-black were slowly impregnated with three pounds of raw hemp-oil; and the accension ensued after nine hours.

Three quarters of a pound of German *rahm* were slowly impregnated with a pound and a half of hemp-oil varnish. The mixture remained 70 hours before it became hot and reeking; it then gradually became hotter, and emitted a strong exhalation; the effluvia were moist, and not inflammable. The reaction lasted 36 hours, during which the heat was one while stronger, and then weaker, and at length quite ceased.

Stove or chimney soot, mostly formed from birch-wood smoke, was mingled with the above-mentioned substances and tied up; the compound remained cold and quiet.

Russian fir-black, mixed with equal parts of oil of turpentine, and bound up, exhibited not the least reaction or warmth.

Birch oil, mixed with equal parts of Russian fir-black, and bound up, began to grow warm and to emit a volatile smell; but the warmth soon went off again.

From the experiments of the admiralty and of Mr Georgi, we learn, not only the decisive certainty of the self-accension of soot and oil, when the two substances are mixed under certain circumstances, but also the following particulars:

Of the various kinds of soot, or lamp-black, the experiments succeeded more frequently and surely with the coarser, more unctuous, and heavier, like Russian painters black, than with fine light German *rahm*, or with coarse chimney-soot. In regard to oils, only those experiments succeeded which were made with drying oils, either raw or boiled. The proportions of the soots to the oils were, in the successful experiments, very various; the mixture kindled with a tenth, a fifth, a third, with an equal, and likewise with a double, proportion of oil. In general, however, much more depends on the mode of mixture, and the manipulation, and, as Mr Georgi often observed, on the weather; for in moist weather the bundles, after becoming warm, would frequently grow cold again.

The instances of spontaneous inflammation hitherto mentioned have been only of vegetable substances; but we have examples of the same thing in the animal kingdom. Pieces of woollen cloth, which had not been scoured, took fire in a warehouse. The same thing happened to some heaps of woollen yarn; and some pieces of cloth took fire in the road, as they were going to the fuller. These inflammations always take place where the matters heaped up preserve a certain degree of humidity, which is necessary to excite a fermentation; the heat resulting from which, by drying the oil, leads them insensibly to a state of ignition; and the quality of the oil, being more or less deficcative, very much contributes thereto.

The woollen stuff prepared at Sevennes, which bears the name of Emperor's stuff, has kindled of itself, and burnt to a coal. It is not unusual for this to happen to woollen stuffs, when in hot summers they are laid in a heap in a room but little aired.

In June 1781, the same thing happened at a wool-comber's in a manufacturing town in Germany, where a heap of wool-combings, piled up in a close warehouse seldom aired, took fire of itself. This wool had been by little and little brought into the warehouse; and, for want of room, piled up very high, and trodden down, that more might be added to it. That this combed wool, to which, as is well known, rape-oil mixed with butter is used in the combing, burnt of itself, was sworn by several witnesses. One of them affirmed

Inflammation.

firmed that, ten years before, a ſimilar fire happened among the flocks of wool at a clothier's, who had put them into a caſk, where they were rammed hard, for their eaſier conveyance. This wool burnt from within outwards, and became quite a coal; it was very certain that neither fire nor light had been uſed at the packing, conſequently the above fires aroſe from ſimilar cauſes. In like manner, very credible cloth-workers have certified, that, after they have bought wool that was become wet, and packed it cloſe in their warehouſe, this wool has burnt of itſelf; and very ſerious conſequences might have followed, if it had not been diſcovered in time.

Nay, there are inſtances, though they be but rare, of human bodies being conſumed by ſpontaneous inflammation. In the Philoſophical Tranſactions, and in the Memoirs of the Academies of Paris and Copenhagen, it is related that an Italian lady (the Counteſs Cornelia Bandi) was entirely reduced to aſhes, except her legs; that an Engliſh woman, called Grace Pitt, was almoſt entirely conſumed by a ſpontaneous inflammation of her viſcera; and, laſtly, that a prieſt of Bergamo was conſumed in the ſame manner. Theſe ſpontaneous inflammations have been attributed to the abuſe of ſpirituous liquors; but though the victims of intemperance are indeed very numerous, theſe certainly do not belong to that number.

The mineral kingdom alſo often affords inſtances of ſpontaneous inflammation. Pyrites heaped up, if wetted and expoſed to the air, take fire. Pitcoal alſo, laid in heaps, under certain circumſtances, inflames ſpontaneouſly. M. Duhamel has deſcribed two inflammations of this nature, which happened in the magazines of Breſt, in the years 1741 and 1757. Cuttings of iron, which had been left in water, and were afterwards expoſed to the open air, gave ſparks, and ſet fire to the neighbouring bodies. For this obſervation we are obliged to M. de Charpentier.

The cauſes of theſe phenomena the chemiſt will aſſign; but they are here recorded as a warning to tradeſmen and others. It is evident, from the facts which have been related, that ſpontaneous inflammations being very frequent, and their cauſes very various, too much attention and vigilance cannot be uſed to prevent their dreadful effects. And conſequently it is impoſſible to be too careful in watching over public magazines and ſtorehouſes, particularly thoſe belonging to the ordnance, or thoſe in which are kept hemp, cordage, lampblack, pitch, tar, oiled cloths, &c. which ſubſtances ought never to be left heaped up, particularly if they have any moiſture in them. In order to prevent any accident from them, it would be proper to examine them often, to take notice if any heat is to be obſerved in them, and, in that caſe, to apply a remedy immediately. Theſe examinations ſhould be made by day, it not being adviſable to carry a light into the magazines; for when the fermentation is ſufficiently advanced, the vapours which are diſengaged by it are in an inflammable ſtate, and the approach of a light might, by their means, ſet fire to the ſubſtances whence they proceed. Ignorance of the fore-mentioned circumſtances, and a culpable negligence of thoſe precautions which ought to be taken, have often cauſed more misfortunes and loſs than the moſt contriving malice: it is therefore of great importance that theſe facts ſhould be univerſally known, that public utility may reap from them every poſſible advantage.

Informed, || Ink.

INFORMED Stars, or Informes Stellæ, are ſuch ſtars as have not been reduced into any conſtellation; otherwiſe called Sporades.—There was a great number of this kind left by the ancient aſtronomers; but Hevelius, and ſome others of the moderns, have provided for the greater part of them, by making new conſtellations.

INGRAHAM, *Port*, on the weſtern ſide of Waſhington Iſland, on the N. W. coaſt of N. America, is divided into two parts by Young Frederick's Iſland. It is a fine harbour for wintering in, being near the ſea, and having deep water. N. lat. 53° 37′, W. long. 133° 18′.—*Morſe.*

Ingraham *Iſles*, in the South Pacific ocean, lie N. N. W. of the Marqueſas Iſlands, from 35 to 50 leagues diſtant, and are 7 in number, viz. *Ooboona*, or Waſhington; *Wooapoo*, or Adams; Lincoln; *Nooheeva*, or Federal; *Tatoo-e-tee*, or Franklin; Hancock, and Knox. The names in Italic are thoſe by which they are known to the natives. The others were given them by Captain Joſeph Ingraham, of Boſton in Maſſachuſetts, commander of the brigantine Hope of Boſton, who diſcovered them on the 19th of April, 1791, a day remarkable in the annals of America, the revolutionary war having commenced on that day in 1775, and the firſt diſcoveries made under the flag of the United States marked its 16th anniverſary. Theſe iſlands, lying between 8° 3′ and 9° 24′ S. lat. and between 140° 19′ and 141° 18′ W. long. from Greenwich, are moſtly inhabited, and appear to be generally variegated with hills and vallies, abounding with timber, and very pleaſant. *Nooheeva*, or Federal iſland, is repreſented by the natives to be the largeſt, moſt populous and productive of the whole; which, they ſay, are 10 in number. The people reſemble thoſe of the Marqueſas Iſlands; as do their canoes, which are carved at each end. Cotton of a ſuperior quality grows here. The natives were friendly. Before Ingraham's diſcovery was known, Captain Joſiah Roberts, of Boſton, ſailed in the ſhip Jefferſon for the N. W. Coaſt, and likewiſe diſcovered theſe iſlands. As theſe iſlands lie in that part of the Pacific Ocean, through which veſſels from Europe or America, bound to the N. W. Coaſt, muſt paſs, and are not far out of their uſual track, they may be viſited for refreſhment in caſe of need.—*ib.*

INIRCHIA RIVER, or *Caguela*, the name of Orinoco river, at its ſource in the mountains, weſtward, between New Granada and Peru, not far from the South Sea.—*ib.*

Sympathetic INK is an old invention. Among the methods by which Ovid teaches young women to deceive their guardians, when they write to their lovers, he mentions that of writing with new milk, and of making the writing legible by coal-duſt or ſoot.

Tuta quoque eſt, fallitque oculos, e lacte recenti
Litera: carbonis pulvere tange, leges.

It is obvious, that any other colourleſs and glutinous juice, which will hold faſt the black powder ſtrewed over it, will anſwer the purpoſe as well as milk; and therefore Pliny recommends the milky juice of certain plants to be uſed.

There

There are several metallic solutions perfectly colourless, or, at least, without any strong tint, which being wrote with, the letters will not appear until the paper be washed over with another colourless solution, or exposed to the vapour of it; but among all these there is none which excites more astonishment, or from which naturalists can draw more conclusions, than that which consists of a solution of lead in vegetable acid, and which by the vapour of arsenical liver of sulphur becomes black, even at a considerable distance. This ink, which may be used by conjurors, proves the subtlety of vapour, and the porosity of bodies; as the change or colouring takes place even when the writing is placed on the other side of a thin wall.

We knew before, that a solution of lead, treated in this manner, would answer the purpose of a sympathetic ink (see that article *Encycl.*); but we did not know, nor do we yet believe, that the sulphuric vapours will act upon the writing through *a wall*. Such, however, is the affirmation of Professor Beckmann, who gives an account of a still more wonderful ink from Peter Borel. This author, in a book called *Historiarum et observationum medico-physic. centuriæ quatuor*, printed at Paris, first in 1653, and afterwards in 1657, gives a receipt for making this ink, which he calls *magnetic waters which act at a distance*. The receipt is as follows:

"Let quick-lime be quenched in common water, and while quenching, let some orpiment be added to it (this, however, ought to be done by placing warm ashes under it for a whole day), and let the liquor be filtered, and preserved in a glass bottle well corked. Then boil litharge of gold, well pounded, for half an hour with vinegar, in a brass vessel, and filter the whole through paper, and preserve it also in a bottle closely corked. If you write any thing with this last water, with a clean pen, the writing will be invisible when dry; but if it be washed over with the first water it will become instantly black. In this, however, there is nothing astonishing; but this is wonderful, that though sheets of paper without number, and even a board, be placed between the invisible writing and the second liquid, it will have the same effect, and turn the writing black, penetrating the wood and paper without leaving any traces of its action, which is certainly surprising; but a fetid smell, occasioned by the mutual action of the liquids, deters many from making the experiment. I am, however of opinion, that I could improve this secret by a more refined chemical preparation, so as that it should perform its effect through a wall. This secret (says Borel) I received, in exchange for others, from J. Brosson, a learned and ingenious apothecary of Montpelier."

For making a sympathetic ink of the fifth class mentioned in the *Encyclopædia*, the following process by M. Meyer may be worthy of the reader's notice. It was entered upon in consequence of a receipt for rose-coloured sympathetic ink shewn to him by a traveller. In that receipt cobalt was the principal ingredient, and therefore the first object was to procure cobalt; but M. Meyer, being unwilling to sacrifice pure pieces of cobalt of any considerable size, made choice of one, which was visibly mixed with bismuth, iron, and quartz. He endeavoured to separate the bismuth as much as possible, and also the arsenic, if it should contain any, by bringing it slowly to a red heat; and he succeeded pretty well, as the bismuth flowed from it in abundance; and the arsenic, the quantity of which was small, was volatilised: many globules of bismuth still adhered to it. By bringing it repeatedly to a red heat, and then quenching it in water, it was reduced to such a state as to be easily pulverised. Having poured nitrous acid upon the powder, he obtained by digestion a beautiful rose-red solution; the siliceous earth was separated in the form of a white slime, and by diluting it with water there was deposited a white powder, which was oxyd of bismuth. The solution being filtered, he added to it a solution of potash, and obtained a precipitate inclining more to a yellow than to a red colour. He again poured over it a little of the nitrous acid, by which a part of the oxyd was re-dissolved of a red colour: the remaining part, which had a dark brown colour, was oxyd of iron. From the solution, by the addition of potash, a precipitate was formed, which was now reddish. Having by this process obtained it pure, that he might now prepare from it the wished for red ink, he dissolved the washen pure oxyd of cobalt in different acids. That dissolved in the nitrous acid with a mixture of nitre, gave a green ink like the common: that dissolved in the sulphurous acid, without the addition of salts, gave a reddish ink, which remained after it was exposed to heat, and would not again disappear, even when a solution of nitre was applied; and that dissolved in the muriatic acid, gave a green ink, darker and more beautiful than the common. By dissolving it, however, in the acetous acid, and adding a little nitre, he obtained what he had in view; for it gave, on the application of heat, an ink of a red colour, like that of the *rosa centifolia*, which again disappeared when the paper became cold.

INNA-QUITO, one of the spacious plains upon the N. side of Quito, in Peru.—*Morse*.

INORDINATE Proportion, is where the order of the terms compared is disturbed or irregular. As, for example, in two ranks of numbers, three in each rank, viz. in one rank, - - - - 2, 3, 9,
and in the other rank, - - - - 8, 24, 36,
which are proportional, the former to the latter, but in a different order, viz. - - 2 : 3 : : 24 : 36,
and - - 3 : 9 : : 8 : 24.
then, casting out the mean terms in each rank, it is concluded that - - - - - 2 : 9 : : 8 : 36,
that is, the first is to the 3d in the first rank,
as the first is to the 3d in the 2d rank.

INSCUA RIVER, is laid down in some maps as the north-western and main branch of St Croix river, an eastern water of the Mississippi, rising in the 48th degree of north latitude.—*Morse*.

INSECTS (See *Encycl.*). A number of non-descript little animals was discovered by La Martiniere the naturalist when accompanying Perouse on his celebrated voyage of discovery. These animals he called *insects*, and to many of them he gave particular names. Of these we shall give his description in this place, leaving our readers, as he has left his, to arrange them properly according to the Linnæan classification.

"The insect, which is figured N° 1. inhabits a small prismatic triangular cell, pointed at the two extremities, of the consistence and colour of clear brittle ice; the body of the insect is of a green colour, spotted with small bluish points, among which are some of a golden tinge; it is fixed by a ligament to the lower part of its small

small habitation: its neck is terminated by a small blackish head composed of three converging scales, in the form of a hat, and enclosed between three fins, two of them large and channelled in the upper part (A) and one small, semicircular (B). When it is disturbed, it immediately withdraws its fins and its head into its cell, and gradually sinks into the water by its own specific gravity. Fig. 2. represents the under side of the prism, shewing in what manner it is channelled, in order to allow free passage to the animal when it wishes to shut itself up in it. Fig. 3. represents the profile of the same. The movement carried on by the two larger fins, which are of a softish cartilaginous substance, may be compared to that which would be produced by the two hands joined together in the state of pronation, and forming, alternately, two inclined planes and one horizontal plane: it is by means of this motion that it supports itself on the top of the water, where it probably feeds on fat and oily substances on the surface of the sea." Our author found it near Nootka, on the north-west coast of America, during a calm.

Fig. 4. represents a collection of insects, as our author calls them, consisting only of oval bodies, similar to a soap bubble, arranged in parties of three, five, six, and nine: among them are also some solitary ones. These collections of globules, being put into a glass filled with sea-water, described a rapid circle round the glass by a common movement, to which each individual contributed by simple compression of the sides of its body, probably the effect of the re-action of the air with which they were filled. It is not, however, easy to conceive how these distinct animals (for they may be readily separated without deranging their economy) are capable of concurring in a common motion. "These considerations (says our author), together with the form of the animal, recalled to my mind, with much satisfaction, the ingenious system of M. de Buffon; and I endeavoured to persuade myself, that I was about to be witness to one of the most wonderful phenomena of Nature, supposing that these molecules, which were now employed in increasing or diminishing their number, or performing their revolutions in the glass, would soon assume the form of a new animal of which they were the living materials. My impatience led me to detach two from the most numerous group, imagining that this number might perhaps be more favorable to the expected metamorphosis. I was, however, mistaken. These I examined with more attention than the rest; and the following account is of their proceedings alone. Like two strong and active wrestlers, they immediately rushed together, and attacked each other on every side: sometimes one would dive, leaving its adversary at the surface of the water; one would describe a circular movement, while the other remained at rest in the centre; their motions at length became so rapid as no longer to allow me to distinguish one from the other. Having quitted them for a short time, on my return I found them reunited as before, and amicably moving round the edge of the glass by their common exertions."

Fig. 5. represents a singular animal, which has a considerable resemblance to a little lizard; its body is of a firm, gelatinous consistence; its head is furnished on each side with two small gelatinous horns, of which the two hindermost are situate the furthest inward: its body is provided with four open fan-like paws, and some appendages near the insertion of the tail, and terminates like that of a lizard: the ridge of the back is divided the whole way down by a band of a deep blue; the rest of the body, as well as the inside of its paws, is of a bright silvery white. It appears to be very sluggish in its motions; and when disturbed by the finger, merely turned itself belly upwards, soon afterwards resuming its former position. Fig. 6. represents it reversed. Martiniere caught it during a calm at the landing place on the Bashee-Islands.

INSTITUTE is a name which has lately been substituted for *school* or *academy*. Formerly *institution*, in the propriety of the English language, was sometimes used as a word of the same import with *instruction*; and now *institute* is employed, especially by the admirers of French innovations, to denote what had hitherto been called an academy. When royalty was abolished in France, it would have been absurd to continue the titles *Royal* Academy of Sciences, *Royal* Academy of Inscriptions, &c.; but instead of merely abolishing the word *royal*, and substituting *national* in its stead, it occurred to the fertile brain of Condorcet, to abolish the seven academies themselves, or rather to melt them all down into one great academy; to which was given the appellation of the

National Institute, or *New Academy of Arts and Sciences*. This academy, founded on a decree of the new constitution, was opened on the 7th of December 1795, when Benezech, the then minister for the home department, attended, and the decree of foundation was read; which was to the following purport:

"The Academy of Arts and Sciences belongs to the whole republic, and Paris is its place of residence. Its employment is to aim at bringing all arts and sciences to the utmost perfection of which they are capable. It is to notice every new attempt, and all new discoveries, and to keep up a correspondence with all foreign literary societies. And by the particular orders of the Executive Directory, its first studies are to be directed to those subjects which more immediately tend to the reputation and advantage of the French republic."

The academy is to consist of 288 members, half of whom are to reside in Paris, the other half in the departments; and to them is to be added a certain number of foreigners, as honorary members, confined at present to twenty-four.

The academy is divided into three classes, each class into sections, each section to contain twelve members.

1st class. Mathematics and natural philosophy. This class is divided into ten sections. 1. Mathematics. 2. Mechanical arts. 3. Astronomy. 4. Experimental philosophy. 5. Chemistry. 6. Natural history. 7. Botany. 8. Anatomy and animal history. 9. Medicine and surgery. 10. Animal œconomy, and the veterinary science.

2d class. Morality and politics. This class consists of six sections. 1. Analysis of sensations and ideas. 2. Morals. 3. Legislature. 4. Political economy. 5. History. 6. Geography.

3d class. Literature and the fine arts. This class consists of eight sections. 1. Universal grammar. 2. Ancient languages. 3. Poetry. 4. Antiquities. 5. Painting. 6. Sculpture. 7. Architecture. 8. Music.

For each class a particular room in the Louvre is appropriated. No one can be a member of two classes at the

the same time, but a member of one class may be present at the meetings of any other. Each class is to print, yearly, an account of its transactions.

Four times a-year there are to be public meetings. On these occasions, the three classes meet together. At the end of each year, they are to give a circumstantial account to the legislative body of the progress made in that year in the arts and sciences. The prizes given yearly by each class are to be publicly notified at certain times. The sums requisite for the support of the institution are to be decreed yearly by the legislative body, upon a requisition made by the Executive Directory.

The first forty-eight members were chosen by the Executive Directory, to whom the choice of the remaining members was confided. To the members, residentiary in Paris, is reserved the choice both of the department and the foreign members. On a vacancy in any class, three candidates are named by the class for the choice of the body at large.

Each class is to have, at its place of meeting, a collection of the products, both of nature and art, and a library, according to its particular wants.

The regulations of the institution, with respect to the times of meeting, and its employments, are to be drawn up by the body at large, and laid before the legislative assembly.

The hall in which the body at large holds its meetings, forms part of the west wing of the Old Louvre, at present called the Museum. It formerly went by the appellation of the Hall of Antiques *(Salle des Antiques)*; and as long as the kings inhabited this part of the palace, was occupied by their guards, from which circumstance it obtained the name of the Hall *des Cent Suisses*. It was likewise appropriated to banquets and entertainments, given by the court on gala days; and it was to this place that Henry IV. was conveyed, on his assassination by Ravaillac, in the *Rue de la Ferronnerie*.

It was built at the same time with the rest of this part of the Louvre, about the year 1528, after the designs of Pierre Lescot, abbot of Clagny. It is 144 feet in length, and 40 in breadth, and holds from 1000 to 1200 persons. In order to adapt it to its new destination, the floor has been sunk, which gives a greater air of lightness to the roof. In the centre stands a double table, in the form of a horse-shoe, supported by sphinxes, at which the members of the institute take their seats. This table is surrounded by two tiers of benches, which are raised for the accommodation of spectators, who have likewise seats provided for them in the vast embrasures of the windows, and at each extremity of the hall.

Whether science will be advanced by the seven royal academies having been melted into one, time must determine; but candour compels us to acknowledge, that the proceedings of the national institute have hitherto been abundantly interesting. Intimately connected with the national institute is the French system of

National Instruction, which is likewise novel, and therefore sufficiently curious to deserve notice in a Work of this kind. When the Christian religion was abolished in France, it was impossible to continue the universities and other seminaries which were founded by Christians, and obliged by their constitution to teach, whether pure or not, the doctrines of Christianity. They were accordingly all swept away, and a new system of education planned, which was to be carried on in what they call

The Primary Schools.
The Central Schools.
The School of Health.
The School of Oriental Languages.
The Polytechnic School.
The National institute.
The Jury of Public Instruction.
The Commission of Public Instruction.
The Legislative Committee of Instruction. And various other national establishments for the improvement of particular sciences.

The first degree of public instruction is to be met with in the *Ecoles Primarées*, established by a decree of the convention of the second *Pluviose*, in the second year of the republic (A). Every district is furnished with one of these schools; the professors or masters in which are paid from the national treasury; and to which every head of a family, without exception, is compelled by law to send its children for instruction. The subjects taught in these primary or elementary schools are divided into nine classes:

1st, Instructions connected with the physical and moral situation of children, prior to their entering into these schools. *2d*, Similar instructions as a guide to teachers in the national schools. *3d*, The arts of reading and writing. *4th*, The elements of French grammar. *5th*, Elements of arithmetic and geometry, with the theory of the new mensuration. *6th*, The elements of geography. *7th*, Explanations of the principal phenomena and productions of nature. *8th*, Elements of agriculture. *9th*, Elements of republican morals.

Next to the primary schools in rank and consequence are the *Ecoles Centrales*, which were established by a decree of the Convention of the seventh *Ventose* in the third year. They are situated in the capital of every department, bearing the proportion of one central school to 300,000 inhabitants. In these schools the republican youths are taught the sciences, and their application in real life. In each of them are professors for the following branches:

1. For mathematics. 2. Experimental philosophy and chemistry. 3. Natural history. 4. Agriculture and commerce. 5. Logic and metaphysics. 6. Political economy and legislation. 7. The philosophical history of nations. 8. The art of healing. 9. Arts and manufactures. 10. Universal grammar. 11. The belles lettres. 12. The ancient languages. 13. The modern languages. 14. The fine arts.

Each central school is furnished with an extensive public library—a botanic garden—a cabinet of natural history—an apparatus for experimental philosophy—and

(A) We would translate this chronological jargon into the language of Christian Europe, were we not persuaded that the French calendar, the French constitution, and the French institutes, will have the same duration: we trust in God not a long duration. For *Pluviose*, and the other fantastical names of months introduced into this article, see Revolution, *Encycl.* n° 184.

and a collection of machines and models connected with the arts and manufactures.

The professors of each school hold, every month, a public sitting, in which conferences are held relative to subjects connected with the improvement of letters, the sciences, and the arts, which are the most beneficial to society.

The object in the establishment of the primary and central schools was, the general instruction of all classes of the citizens; and it being incompatible with the perfect completion of that important purpose, to expect from them the propagation of particular branches of science, it became necessary to establish other literary and scientific academies.

Accordingly, the French government have founded, *1st*, Schools of health *(les ecoles de fante)*, in Paris, Strasburgh, and Montpelier, where medicine and surgery are studied; which schools are affirmed, by those who find nothing wrong in France, to be the most perfect of their kind, as well as new and unparalleled models for such institutions.

2d, Two schools for Oriental languages, in the national library, and in the college of France.

3d, The Polytechnic school in Paris, or central school for the direction of public works. This establishment is very generally admired and considered as a model for imitation. It contains more than 400 young persons, previously educated in the mathematics, and the majority of them intended for engineers in various lines; and they labour under the immediate direction of their tutors nine hours every day. It occupies the principal part of the *Palais de Bourbon* in Paris, and is furnished with a large collection of instruments and models. The journal of the Polytechnic school, which is published by the booksellers Regent and Bertrand at Paris, is a perfectly original work, and admirably calculated to convey useful information.

Of the national institute a sufficient account has been given in the preceding article. We proceed therefore to the jury of public instruction *(Le Jury Central d'Instruction)*, of which the principal business is to superintend the primary and central schools. It appoints the professors in these schools, and examines into their conduct. Like the legislative body it is renewed by a third every half year. When they have chosen a professor for a central school, they submit their choice to the department; and, in case of disapprobation, they make another appointment. To this jury of public instruction the professors in the central schools are amenable for all misconduct connected with their offices; it may expel them, but all its decisions must be submitted for confirmation to the tribunal of the department.

There is also established at Paris a supreme council, called The commission of Public Instruction, to which is entrusted the whole executive department. The preservation of the national monuments, of public libraries, museums, cabinets, and valuable collections; the superintendance of all the schools and the modes of instruction; all new inventions and scientific discoveries; the regulation of weights and measures; national statistics and political economy, are all placed under the authority of this supreme commission. For the commodious and regular execution of so many complicated branches of business, there is a large office, called *Le Secretariat*, which is divided into three departments.

1. For the regulation of the different kinds of instruction; of the modes of education in the schools; and for the choice of elementary books. 2. For weights and measures; inventions and discoveries; libraries and bibliography; museums, works of art, and literary rewards and encouragements. 3. For theatres, national feasts, republican institutions, and the erection of monuments.

As all public establishments require the superintendance and occasional correction of the legislature, in addition to that of their own immediate executive authority, it has been deemed necessary to appoint a permanent committee of instruction in the legislative body, to provide such sums as may be necessary for the preservation and improvement of this system of instruction. This legislative committee are invested with due authority for these purposes. Their objects are precisely the same as those of the commission of public instruction above described, only with this difference, that the latter superintends the execution of existing laws, whilst the former receives and improves them, or proposes new ones. This committee is divided into three departments, as is the commission, with exactly the same arrangement of their respective labours. The committee being charged with the enaction of all new laws, its members, with a view to obtain accurately all the requisite information relative to the numerous branches of the arts, have procured from the legislative body the appointment of a *commission temporaire des arts* to be annexed to them, and to meet in the same house with them; which temporary commission is divided into sixteen classes: viz. 1. For Zoology; 2. Botany; 3. Mineralogy; 4. Physics; 5. Chemistry; 6. Anatomy; 7. Machinery; 8. Geography; 9. Artillery and Fortification; 10. Medals and Antiquities; 11. Bibliography; 12. Painting; 13. Architecture; 14. Sculpture; 15. Bridges and Causeways; and, 16. Musical Instruments.

The improvements of the national literary and scientific establishments are numerous and important.

1st, By a decree of the convention of the 11th *Prairial*, in the second year, it was enacted, that means should be adopted by which every possible advantage might be derived from the botanic gardens of the republic, in Turkey and other foreign countries. This politic decree clearly tended to render France, in the language of the reporter. *L'abregé de tous les climats, et l'entrepôt de l'Europe.* "The epitome of every climate, and the magazine of Europe." These plants which thrive between the tropics may be cultivated in the south of France; and those which are the produce of northern climates, may be cultivated in the northern departments; by which means, France will be in possession of all foreign plants and drugs, without the exportation of specie.

2d, The National Bibliography was decreed in the sitting of 22d *Germinal*, in the second year. It consists of a complete catalogue of books of all descriptions, the property of the nation; it was then ascertained, that the republic possessed more than ten millions of books. The titles of them were to be adjusted by actual comparisons; the manuscripts to be registered separately; anonymous productions were to be arranged according to their subjects; and those of known authors in the alphabetical order of the names. The several editions to be classed according to their dates; and what may be deemed more important, this French National Bibliography will contain a dictionary of anonymous books, as well as those published under fictitious names, a desideratum in the republic of letters.

3d, The annihilation of all *patois*, or dialects, decreed in the sitting of the 16th *Prairial*, in the second year. Notwithstanding the universality of the French language, and that it was exclusively spoken in the majority of the inland departments, yet there existed thirty various dialects in France. It is more astonishing that Rozier had remarked, that between one neighbouring village and another, there was so considerable a difference in the dialect, that the inhabitants could not understand each other; and the vinestock had thirty different names. The naturalist, Villars, has stated, that in the nomenclature of vegetables, in the departments, he had only met with an hundred which had a common appellation.

4th, The establishment of the *Conservatoire des Arts et Métiers*, was decreed in the sitting of the 8th of *Vendemiaire*, in the third year. This consists of a spacious hall, in the form of an amphitheatre, and contains the instruments and the models of machinery connected with the arts, and a description of their uses, with every book relating to them. Annexed to this establishment are three expositors and a draughtsman, who explain to the students the use of each instrument, and who register every new discovery, which is presented to the *Bureau de Consultation*, to the lyceum of arts, the *ci-devant* academy of sciences, or to the board of commerce.

5th, The establishment of the board of longitude was decreed in the sitting of the 7th of *Messidor*, third year. It was certainly a disgrace under the monarchy, that an astronomical and nautical establishment, which had already proved so beneficial to Great Britain, should not have been adopted in France. In consequence of this decree, the French board is now as complete as the English. It consists of ten members, and has under its jurisdiction the national observatory at Paris, and all the astronomical instruments belonging to the republic. It corresponds with foreign astronomers; delivers public lectures on astronomy and navigation; and its proceedings are annually recited in a public sitting.

6th, The general school of the Oriental languages was established by a decree of the 10th of *Germinal*, in the fourth year. This school adjoins to the national library, and all the books and manuscripts relative to Oriental literature are deposited in it.

7th, The national museum of antiquities was decreed in the sitting of 20th of *Prairial*, fourth year. A school of this description was successfully established at Vienna, by Eckel; at Gottingen, by Heyne; at Leipsick, by Ernest; and even at Strasburgh, by the celebrated Oberlin: Paris was, however, without one. This national archeology, or science of antiquity, is divided into nine different classes: inscriptions, characters, statues, *bas reliefs*, sculptures, paintings, mosaics, medals, civil, religious, and military instruments. This extensive establishment is under the direction of two principal professors; *le Conservateur Professeur, et le Conservateur Bibliothecaire*. The province of the former is to deliver public lectures on the several branches of antiquities, to teach the theory of medals and engravings, the history of the arts among the ancients, &c. The duties of the latter are merely of a bibliographical nature.

8th, The new modelling of the Grand National Library, was decreed in the sitting of 25th *Vendemiaire*, in the fourth year. By virtue of this decree, the place of librarian in chief was suppressed, and the whole establishment placed under a *conservatoire* of eight members; of whom two were appointed for the superintendance of printed books; two for manuscripts; two for antiquities; and two for engravings. From these a temporary director is annually chosen, who superintends the whole, acts occasionally as president of this assembly, and maintains a regular correspondence with the constituted authorities relative to the concerns of the library.

9th, The augmentation of the Museum of Natural History, formerly called *Le Jardin Royal des Plantes*. This establishment was decreed the 15th *Brumaire*, third year, upon a report of Thibadeau, in the name of the committee of Public Instruction. Besides the addition of large rooms, and various other buildings, there are new collections of natural curiosities and productions; and the library is much increased. It is open to the public three times a week. At stated periods all the naturalists in Paris deliver courses of lectures in the various branches of natural history. The museum is said to have received greater improvements from this augmentation than from all the labours of Buffon, or from its foundation, since the time of Tournefort.

10th, The *Ecole des Mines* was established in the *Hotel des Monnaies*, and has for its direction the naturalist Le Sage. This institution is unrivalled in Europe; and the collection of mineralogical curiosities surpasses whatever can be conceived.

11th, The society of natural history in Paris, deservedly classes among those which have rendered the greatest services to the cause of science since the revolution. A lecture of public instruction is held every ten days, which is generally given by one of the members, and which is open to all the lovers of natural history. Premiums are proposed for dissertations; one of which, by the late C. Herman, jun. (whose early decease was a great loss to the republic of letters) on the *apterous* class of insects, may be said to constitute an epocha in the annals of natural history. The society has published a volume of memoirs, in folio, entitled, "*Transactions of the Society of Natural History*." It has likewise erected a statue to the great Linnæus, in the national garden of plants; and, at the period when every public instruction was suspended, gave lectures on the different branches of science belonging to its department. Several intelligent and skilful navigators, among others those sent in search of the unfortunate La Pérouse, as well as those which accompanied Buonaparte on his romantic expedition to Egypt, were members of this society.

This statement of facts relative to the present state of public instruction, the sciences, the arts, and the progress of national literature in France, has been taken from a miscellany, of which the principal writers are well acquainted with what is doing in that distracted country. They call it a sublime system; and seem to consider the increase of the national library, the improvement of the botanic gardens, and the discoveries that have been made by the different schools or institutes, as furnishing a demonstration that the republican government is more favourable to the advancement of

science

science, than the monarchical, whether absolute or limited. But it should not be forgotten, that this system is yet in its infancy; and that in prosecuting new schemes, all men, and more especially Frenchmen, are actuated by an enthusiasm which gradually cools as their pursuits become familiar. We shall therefore venture to predict, that the different schools will not display such ardour twenty years hence as they do at present; and that if the republican government continue thirty years in France, the progress of science in that country will not be more rapid than it was under the monarchy. We must remember, too, that the French libraries, museums, and picture galleries, have been improved by means which the morals of other governments do not employ--by rapine and robbery.

That something may be learned from this system to improve the modes of education in other countries, we admit; and it is for that reason that we have inserted an account of it. But if it contains something worthy of imitation, it contains likewise much to be shunned. We do not think it consistent with the *rights of man* to *compel* parents to send their children to be educated in *particular* schools; especially in schools where not only religious instruction is omitted, but where, there is reason to believe, that the professors are at pains to raze all religious impressions from the youthful mind. In a nation denying the truth of Christianity, it is not to be supposed that the Christian religion will be publicly taught; but in a nation of philosophers, as the French call themselves, it might have been expected that the laws of religious toleration would have been so far regarded, that Christian parents would not have been *compelled* to send their children to *antichristian* schools! But it is not Christianity alone that is neglected in this *sublime* system of education. Though the legislative body has some time ago decreed that there is a God, there is not in any one of those schools the smallest care taken to instruct the republican youth in the principles even of natural religion! We might indeed have looked for it under the title *Metaphysics*, had not the constitution of the National Institute taught us, that French metaphysics attend to nothing but the analysis of sensations and ideas. Yet the legislators might have listened on this subject to a republican as sound as themselves, and who was likewise no friend to superstition. "Nam et Majorum instituta tueri sacris, ceremoniisque retinendis sapientis est. Non solum ad religionem pertinet, sed etiam ad *civitatis* statum, ut sine iis, qui sacris publice præsunt, religioni privatæ satisfacere non possint." *Cicero de Nat. Deorum.*

INSURANCE, in law and commerce, though an excellent institution, is not of high antiquity. The oldest laws and regulations concerning insurance, with which the indefatigable Beckmann is acquainted, are the following:

On the 28th of January 1523, five persons appointed for that purpose drew up at Florence some articles which are still employed on the exchange at Leghorn. These important regulations, together with the prescribed form of policies, which may be considered as the oldest, have been inserted, in Italian and German, by Magens, in his Treatise on Insurance, average, and bottomry, published at Hamburgh in 1753.

There is still preserved a short regulation of the 25th May 1537, by the Emperor Charles V. respecting bills of exchange and insurance, in which the strictly fulfilling only of an agreement of insurance is commanded.

In the year 1556, Philip II. king of Spain, gave to the Spanish merchants certain regulations respecting insurance, which are inserted by Magens, with a German translation, in his work before-mentioned. They contain some forms of policies on ships going to the Indies.

In the year 1598, the *Kamer van assurantie*, chamber of insurance, was established at Amsterdam. An account of the first regulations of this insurance office may be seen in Pontanus's History of the city of Amsterdam, and in other works.

In the year 1600, regulations respecting insurance were formed by the city of Middelburg in Zealand.

It appears that the first regulations respecting insurances in England, which may be seen in *Anderson's History of Commerce*, were made in the year 1601. We find by them, that insurers had before that period conducted themselves in such a manner, that the utmost confidence was reposed in their honesty, and that on this account few or no disputes had arisen.

Of the various policies for insurance in England, a pretty accurate account will be found in the *Encyclopædia*; but there is one of them, of which our account must be acknowledged to be now defective. This is,

Insurance on lives; which is a policy that has greatly increased, in consequence of its utility being more generally understood. Of the two offices for life-assurances, noticed in that article, the former, entitled the *Amicable Society*, has extended the number of its shares to 4000; but, as we have already observed, the nature of the institution is too limited to become of general importance. The latter, entitled, the *Society for Equitable Assurances on Lives and Survivorship*, is undoubtedly one of the most important institutions of the kind, as will appear by the following account, with which we have been favoured by an obliging correspondent, and upon the accuracy of which our readers may depend:

The members of the equitable society, finding, in June 1777, that their affairs were in a flourishing situation, resolved to reduce their annual premiums one tenth; and in 1782, adopted new tables agreeable to the probabilities of life at Northampton, in lieu of those they had hitherto used, formed from the London bills of mortality. But though it was evident, that the new tables were much better adapted for assuring promiscuously persons residing in the country, or in large towns, it was thought proper, for greater security, to make an addition of 15 per cent. to the real value of the assurances, as computed from the table of mortality at Northampton; and with the view of making an adequate compensation to the assured for their former payments, which had been so much higher than would be required by the new rates, an addition was made to their claims of L.1 : 10s. per cent. for every premium they had paid. The consequence of these measures proved highly favourable to the society; for its business increased so fast, that in 1785 it was nearly doubled; the sums assured amounting to upwards of L.720,000. At this period, the favourable result of a minute and very laborious investigation of the state of the society, induced them to take off the 15 per cent. charged upon the premiums in 1782, and make a further addition to the claims of L.1 per cent. for every payment made prior to the 1ſt January 1786. A ſtill greater increaſe of ſucceſsful buſineſs determined them, in 1791, to make another addition of L.1 per cent. to the claims; and in the following year, a further addition of L.2 per cent.; by which the claims upon aſſurances of the year 1770 were more than doubled; and thoſe of an earlier date increaſed in a ſtill higher proportion. By theſe advantages to its members, and the honourable and truly equitable manner in which the concerns of the ſociety are tranſacted, the augmentation of their buſineſs has been ſo great, that on the 31ſt December 1792, the ſums aſſured (without including the additions made to them) amounted to upwards of L.3,000,000; and on the 31ſt December 1795, to about L.4,000,000.

The rates of aſſurance, as reduced to their real values in 1786, and according to which the ſociety now tranſact buſineſs, are as follows:

Sum Aſſured £.100.

Age.	*One Year.*	*Seven Years.*	*Whole Life.*
15	£.0 17 11	£.1 2 11	£.1 18 7
20	1 7 3	1 9 5	2 3 7
25	1 10 7	1 12 1	2 8 1
30	1 13 3	1 14 11	2 13 4
35	1 16 4	1 18 10	2 19 10
40	2 0 8	2 4 1	3 7 11
45	2 6 8	2 10 10	3 17 11
50	2 15 1	3 0 8	4 10 10
55	3 5 0	3 12 0	5 6 4
60	3 18 1	4 7 1	6 7 4
65	4 15 2	5 10 10	7 16 9

The other offices in London for the aſſurance of lives are, the *Royal Exchange Aſſurance*, the *Weſtminſter, Society*, and the *Pelican Life Office*.

The corporation of the *Royal Exchange Aſſurance* was empowered to aſſure lives by its ſecond charter, dated 29th April 1721; but the original object of the company being ſea aſſurances, and the true principles of aſſuring on lives being at that time little underſtood, this branch of their buſineſs was at firſt comparatively ſmall: they generally required a premium of five or ſix guineas per cent. without any regard to the age; and the aſſurance, which was uſually for a ſmall ſum, was ſeldom for a greater term than one year. In this manner they continued to aſſure upon lives till the end of the year 1783, when the increaſing importance of this part of their buſineſs, which they had ſome years felt, induced them to adopt a regular table of rates of aſſurance, according to the Northampton regiſters of mortality, but with a greater addition to the real values than had been made by the "Society for Equitable Aſſurances on Lives and Survivorſhip." This was thought proper, from the conſideration that the aſſurers with the Royal Exchange company are not in any caſe liable to a call upon them beyond the premium they engage to pay, and have the ſecurity of the capital and funds of the company ariſing from the other branches of their buſineſs; however, the company, finding themſelves ſucceſsful in their life aſſurances, determined, in 1790, to reduce their premiums; and in 1797 made a ſtill greater reduction, by which they are brought very near to thoſe above ſtated. This company have agents in all the principal towns of Great Britain, and are impowered to aſſure lives in all parts of the world.

The *Weſtminſter Society* was eſtabliſhed in 1792, for aſſuring lives, and granting annuities. Their terms are nearly the ſame as thoſe of the Royal Exchange Aſſurance; but not being a corporate body, every perſon aſſuring ſigns a declaration, that he accepts the joint ſtock of the ſociety as his ſecurity.

The *Pelican Life Office* was inſtituted in 1797, by ſome of the principal proprietors of the Phœnix Fire Office. The rates which they have publiſhed vary conſiderably from thoſe of the other offices; but whether they are founded on more juſt principles, time and experience muſt determine. This ſociety alſo makes a new ſpecies of aſſurance, by way of endowment for daughters, or for children generally, when they ſhall attain the age of twenty-one years.

INTEGRAL CALCULUS, in the new analyſis, is the reverſe of the differential calculus, and is the finding of the integral from a given differential; being ſimilar to the inverſe method of fluxions, or the finding the fluent to a given fluxion. See FLUXIONS, *Encycl.*

INTEREST, is the allowance given for the uſe of money by the borrower to the lender, and is either *ſimple* or *compound*. The method of computing both intereſts is explained in the article ALGEBRA, (*Encycl.*) page 427, &c.; and the ſubject of ſimple intereſt is again reſumed in ARITHMETIC, (*Encycl.*) n° 20. The application of the canons for the computation of compound intereſt, to the value of annuities, the only caſe in which that intereſt is allowed by the laws of this country, may be ſeen in the articles ANNUITY and SURVIVORSHIP, (*Encycl.*); where various tables are given to facilitate the different computations. Some of our readers, however, have expreſſed a wiſh to have the rule for computing compound intereſt ſo ſtated, as to be underſtood by thoſe who are unacquainted with algebraic ſymbols. Their wiſh may be eaſily gratified.

The general formula $S = p R^t$ anſwers for the amount of any ſum, whether the intereſt be payable yearly, half-yearly, quarterly, or daily. Let R denote the amount of one pound for the firſt payment, and t the number of payments, the unit being from the commencement till the firſt payment is due; alſo, let l denote the logarithm of any quantity before which it is wrote; then, from the known property of logarithms, the theorem may be expreſſed thus, $l. S = l. p + l. R \times t$.

Required the amount of L.250 at 5 per cent. compound intereſt, for 12 years, reckoning the intereſt payable yearly, half-yearly, quarterly, and daily?

Yearly. $p = 250$, $R = 1{\cdot}05$, $t = 12$.

$$\begin{array}{r} 0{\cdot}0211893 = l.\,R \\ 12 \\ \hline {\cdot}2542716 = l.\,R \times t. \\ 2{\cdot}3979400 = l.\,p. \end{array}$$

$l. S = 2{\cdot}6522116$—L.448 : 19 : $3\frac{1}{4}$ = Amount.
250

198 : 19 : $3\frac{1}{4}$ = Comp. intereſt.

Half

Half yearly, $p = 250$, $R = 1{\cdot}025$, $t = 24$.

$$\begin{array}{r} 0{\cdot}0107239 = l.\ R. \\ 24 \\ \hline 428956 \\ 214478 \\ \hline {\cdot}2573736 = l.\ R \times t. \\ 2{\cdot}3979400 = l.\ p. \\ \hline \end{array}$$

$l.\ S = 2{\cdot}6553136$ — L.452 : 3 : $7\frac{1}{4}$ = Amount.
250
202 : 3 : $7\frac{1}{4}$ = Interest.

Quarterly. $p = 250$, $R = 1{\cdot}0125$, $t = 48$.

$$\begin{array}{r} 0{\cdot}0053950 = l.\ R. \\ 48 \\ \hline 431600 \\ 215800 \\ \hline {\cdot}2589600 = l.\ R \times t. \\ 2{\cdot}3979400 = l.\ p. \\ \hline \end{array}$$

$l.\ S = 2{\cdot}6569000$ — L.453 : 16 : $8\frac{3}{4}$ = Amount.
250
203 : 16 : $8\frac{3}{4}$ = Interest.

Daily, $p = 250$, $R = 1 + \frac{\cdot 05}{365} = \frac{365{\cdot}05}{365}$, $t = 365 \times 12$.

$$\begin{array}{r} 2{\cdot}5623524 \\ 2{\cdot}5622929 \\ \hline {\cdot}0000595 = l.\ R. \\ 4380 \\ \hline 47600 \\ 1785 \\ 2380 \\ \hline {\cdot}2606100 = l.\ R \times t. \\ 2{\cdot}3979400 = l.\ p. \\ \hline \end{array}$$

$l.\ S = 2{\cdot}6585500$ — L.455 : 11 : $3\frac{1}{2}$ = Amount.
250
205 : 11 : $3\frac{1}{2}$ = Interest.

INTERPOLATION, in the modern algebra, is used for finding an intermediate term of a series, its place in the series being given. See ALGEBRA and SERIES, *Encycl.*

The method of interpolation was first invented by Mr Briggs, and applied by him to the calculation of logarithms, &c. in his Arithmetica Logarithmica, and his Trigonometria Britannica; where he explains, and fully applies, the method of interpolation by differences. His principles were followed by Reginal and Mouton in France, and by Cotes and others in England. Wallis made use of the method of interpolation in various parts of his works; as his arithmetic of infinites, and his algebra, for quadratures, &c. The same was also happily applied by Newton in various ways: by it he investigated his binomial theorem, and quadratures of the circle, ellipse, and hyperbola. See Wallis's Algebra, chap. 85. &c. Newton also, in lemma 5. lib. 3. Princip. gave a most elegant solution of the problem for drawing a curve line through the extremities of any number of given ordinates; and in the subsequent proposition, applied the solution of this problem to that of finding, from certain observed places of a comet, its place at any given intermediate time. And Dr Waring, who adds, that a solution still more elegant, on some accounts, has been since discovered by Mess. Nichol and Stirling, has also resolved the same problem, and rendered it more general, without having recourse to finding the successive differences. *Philos. Trans.* vol. 69. part 1. art. 7.

INTERSCENDENT, in algebra, is applied to quantities, when the exponents of their powers are radical quantities. Thus $x^{\sqrt{2}}$, $x^{\sqrt{a}}$, &c. are interscendent quantities.

INTERSTELLAR, a word used by some authors to express those parts of the universe that are without and beyond the limits of our solar system.

INTRADOS, the interior and lower side, or curve, of the arch of a bridge, &c. In contradistinction from the extrados, or exterior curve, or line on the upper side of the arch. See ARCH in this *Suppl.*

INVERNESS, NEW, a town on the river Alatamaha, in Georgia, built by a company of emigrants from the Highlands of Scotland, 130 of whom were brought over by Gen. Oglethorpe in 1734. It is about 20 miles from Frederica. These settlers presented a most pathetic and prophetic remonstrance to Gen. Oglethorpe in January, 1738, against the introduction of slaves into the colony.—*Morse.*

INVOLUTION and EVOLUTION, are terms introduced into geometry by the celebrated Mr Huyghens, to express a particular manner of describing curvilineal spaces which occurred to him when occupied in the improvement of his noble invention of pendulum clocks. Although he was even astonished at the accuracy of their motion, and they soon superseded all balance clocks, he knew that the wide vibrations were somewhat slower than the narrow ones, and that a circle was not sufficiently incurvated at the sides to render all the vibrations isochronous. The proper curve for this purpose became an interesting object. By a most accurate investigation of the motions of heavy bodies in curved paths, he discovered that the cycloid was the line required. Lord Brouncker had discovered the same thing, as also Dr Wallis. But we do not imagine that Huyghens knew of this; at any rate, he has the full claim to the discovery of the way of making a pendulum oscillate in a cycloidal arch. It easily occurred to him, that if the thread by which the pendulum hangs be suspended between two curved cheeks, it would alternately lap on each of them in its vibrations, and would thus be raised out of the circle which it describes when suspended from a point. But the difficulty was to find the proper form of those cheeks. Mr Huyghens was a most excellent geometer, and was possessed of methods unknown to others, by which he got over almost every difficulty.

difficulty. In the present case there was fortunately no difficulty, the means of solution offering themselves almost without thought. He almost immediately discovered that the curve in question was the same cycloid. That is, he found, that while a thread unwinds from an arch of a cycloid, beginning at the vertex, its extremity describes the complementary arch of an equal cycloid.

Thus he added to this curve, already so remarkable for its geometrical properties, another no less curious, and infinitely exceeding all the others in importance.

The steps by which this property was discovered are such direct emanations from general principles, that they immediately excited the mind of Mr Huyghens, which delighted in geometry, to prosecute this method of describing or transforming curve lines by evolution. It is surprising that it had not ere this time occurred to the ancient geometers of the last century, and particularly to Dr Barrow, who seems to have racked his fancy for almost every kind of motion by which curve lines can be generated. Evolution of a thread from a curve is a much more obvious and conceivable genesis than that of the cycloid invented by Mersennus, or that of the conchoid by Nicomedes, or those of the conic sections by Vieta. But except some vague expressions by Ptolemy and Gassendus, about describing spirals by a thread unlapped from a cylinder, we do not recollect any thing of the kind among the writings of the mathematicians; and it is to Huyghens alone that we are indebted for this very beautiful and important branch of geometry. It well deserves both of these epithets. The theorems which constitute the doctrines of evolution are remarkable for their perspicuity and neatness. Nothing has so much contributed to give us clear notions of a very delicate subject of mathematical discussion, namely curvature, and the measure and variations of curvature. It had become the subject of very keen debate; and the notions entertained of it were by no means distinct. But nothing can give such a precise conception of the difference of curvature, in the different parts of a cycloid or other curve, as the beholding its description by a radius continually varying in length. This doctrine is peculiarly valuable to the speculator in the higher mechanics. The intensity of a deflecting force is estimated by the curvature which it induces on any rectilineal motion; and the variations of this intensity, which is the characteristic of the force, or what we call its nature, is inferred from the variations of this curvature. The evolution and involution of curve lines have therefore great claim to our attention. But a Work like ours can only propose to exhibit an outline of the subject; and we must refer our readers to those eminent authors who have treated it in detail. Varignon, in the Memoirs of the French Academy for 1706, has been at immense pains to present it in every form; James Bernoulli has also treated the subject in a very general and systematic manner. Some account is given of it in every treatise of fluxions. We recommend the original work of Mr Huyghens in particular; and do not hesitate to say, that it is the finest specimen (of its extent) of physico-mathematical discussion that ever has appeared. Huyghens was the most elegant of all modern geometers; and both in the geometrical and physical part of this work, *De Horologio Oscillatorio*, he has preserved the utmost rigour of demonstration, without taking one step in which Euclid or Apollonius would not have followed him.

—————— *juvat integros accedere fontes*
Atque haurire.

Such authors form the taste of the young mathematician, and help to preserve him from the almost mechanical procedure of the expert symbolical analyst, who arrives at his conclusion without knowing how he gets thither, or having any notions at all of the magnitudes of which he is treating.

There are two principal problems in this doctrine.

I. To ascertain the nature of the figure generated by the evolution of a given curve.

II. To determine the nature of the curve by whose evolution a given curve may be generated.—We shall consider each of these in order, and then take the opportunity which this subject gives of explaining a little the abstruse nature of curvature, and its measures and variations, and take notice of the opinions of mathematicians about the precise nature of the angle of contact.

Plate xxxi.

The curve line ABCDEF (fig. 1.) may be considered as the edge of a crooked ruler or mould; a thread may be supposed attached to it at F, and then lapped along it from F to A. If the thread be now led away from A, keeping it always tight, it is plain that the extremity A must describe a curve line A *b c d e f*, and that the detached parts of the thread will always be tangents to the curve ABCDEF. In like manner will the curve line F *d′ c′ b′* A′ be described by keeping the thread fast at A, and unlapping it from the other end of the mould.

This process was called by Mr Huyghens the Evolution of the curve ADF. ADF is called the Evolute. A *d f* was named by him the Curve by Evolution. It has been since more briefly termed the Evolutrix, or unlapper. It has also been called the Involute; because, by performing the process in the opposite direction *f d* A, the thread is lapped up on the mould, and the whole space ADF *f d* A is folded up like a fan. The detached parts C *c*, D *d*, or C *c′*, D *d′*, &c. of the thread, are called Radii of the Evolute; perhaps with some impropriety, because they rather resemble the momentary radii of the evolutrix. We may name them the evolved radii. The beginning A of evolution may be considered as the vertex of the curves, and the ends F and *f* may be called the terms.

There is another way in which this description of curve lines may be conceived. Instead of a thread F *f* gradually lapped up on the mould, we may conceive F *f* to be a straight edged ruler applied to the mould, and gradually rolled along it without sliding, so as to touch it in succession in all its points. It is evident, that by this process the point *f* will describe the curve *f d* A, while the point F describes the other curve F *d′ a′*. This way of conceiving it gives a great extension to the doctrine, and homologates it with that genesis of curve lines by which cycloids of all kinds are described, and which we may distinguish by the name of Provolution. For it is plain, that the relative motions of the points A and *b* are the same, whether the ruler *b* B *b′* roll on the mould ABF, or the mould roll on the ruler: but there will be a great difference in the form of the line traced by the describing point, if we suppose the plane

plane on which it is traced to be attached to the rolling figure. Thus, when a circle rolls on a ſtraight line, a point in its circumference traces a cycloid on the plane attached to the ſtraight line, while the point of the ſtraight line which quitted the circle deſcribes on the plane attached to the circle another line; namely, the involute of the circle. This mode of deſcription allows us to employ a curved ruler in place of the ſtraight one b B b'; and thus gives a vaſt extenſion to the theory. But at preſent we ſhall confine ourſelves to the employment of the ſtraight line b B b', only keeping in mind, that there is an intimate connection between the lines of evolution and of provolution.

By the deſcription now given of this proceſs of evolution and involution, it is plain,

1. That the evolution is always made from the convex ſide of the evolute.

2. That the evolved radii B b, C c, D d, &c. are reſpectively equal to the arches BA, CA, DA, &c. of the evolute which they have quitted; and that b B b', c C c', d D d, &c. are always equal to the whole arch ADF.

3. That any point B of the lapped up thread deſcribes during its evolution a curve line B $\gamma\,\delta\,\epsilon\,\varphi$ parallel to $b\,c\,d\,e\,f$; becauſe theſe curves are always equidiſtant from each other.

4. That if the thread extend beyond the mould as a tangent to it, the extremity α will deſcribe a parallel or equidiſtant curve $\alpha\,\beta\,\gamma\,\delta\,\epsilon\,\varphi$, lying without A $b\,c\,d\,e\,f$. From this it appears that B $\gamma\,\delta\,\epsilon\,\varphi$ is the complete evolutrix of FEDCB, while $bdeef$ is the evolutrix of that arch, and the added tangent B b. In like manner, the lapped up thread ADF, with the added part F φ', deſcribes the evolutrix $\varphi'\,\epsilon'\,\delta'\,\gamma'\,\beta'$ A'.

5. If from any point C of the evolute there be drawn lines C b, C c, C d, C e, &c. to the evolutrix, thoſe which are more remote from the vertex are greater than theſe which are nearer. Draw B b, c C, d D, e E, touching the evolute. C b is leſs than CB + B b; that is (2), than C c. Again, DC + C c is equal to D d, which is leſs than DC + C d. Therefore C c is leſs than C d. Now let C e cut D d in r. Then $e\,r$ + r DE is greater than e E. But e E is equal to $d\,r$ + r DE. Therefore $e\,r$ is greater than $d\,r$; and $e\,r$ + r C is greater than $d\,r$ + r C, which is greater than c C. Therefore e C is greater than c C.

6. Hence it follows, that a circle deſcribed round any point of the evolute, with a radius reaching to any point of the evolutrix, will cut the evolutrix in that point, and be wholly within it on the ſide remote from the vertex, and without it on the ſide next the vertex.

7. The evolved radius cuts every arch of the evolutrix perpendicularly, or a right line drawn through the interſection at right angles touches the evolutrix in that point. Through any point d draw the line $m\,d\,t$ at right angles to d D. The part of it $m\,d$ next to the vertex is wholly without the curve, becauſe it is without the circle deſcribed round the centre D; and this circle is without the evolutrix on that ſide of d which is next the vertex (6). Any point t on the other ſide of d is alſo without the curve. For let $t\,e$ E be another evolved radius, cutting D d in n: then $n\,d$ is leſs than $n\,t$, becauſe $n\,d\,t$ is a right angle by conſtruction; and therefore $n\,t\,d$ is acute. But becauſe E n + n D are greater than ED, E n + $n\,d$ are greater than ED + D d, that is, than E e, and $n\,d$ is greater than $n\,e$. Therefore, ſince it is leſs than $n\,t$, it follows that $n\,e$ is much leſs than $n\,t$, and t lies without the curve. Therefore the whole line $m\,d\,t$ is without the curve, except in the point d. It therefore touches the curve in d, and the radius D d cuts it at right angles in that point. By the ſame reaſoning, it is demonſtrated, that all the curves A $b\,d\,f$, $\alpha\,\beta\,\delta\,\varphi$, A' $b'\,d'\,f'$, $\alpha'\,\beta'\,\delta'\,\varphi'$, are cut perpendicularly by the tangents to the evolute. Alſo all theſe curves interſect the evolute at right angles in their vertexes.

It follows from this propoſition, that from every point, ſuch as s, or i, or o, &c. in the ſpace AOF comprehended by the evolute and its extreme tangents AO, FO, two perpendiculars may be drawn to the evolutrix A $d\,f$; and that from any point in the ſpace within the angle A $o\,f$ only one perpendicular can be drawn; and that no perpendicular can be drawn from any point on the other ſide of ADF. Apollonius had obſerved theſe circumſtances in the conic ſections, but had not thought of marking the boundary formed by the evolute ADE. Had he noticed this, he would certainly have diſcovered the whole theory of evolution, and its importance in ſpeculative geometry.

It alſo follows from this propoſition, that if a curve A $b\,c\,d\,e\,f$ is cut by the tangents of ABCDEF at right angles in every point, it will be deſcribed by the evolution of that curve: For if the evolutrix, whoſe vertex is A, be really deſcribed, it will coincide with A $b\,c\,d$ in A, and have the ſame tangent; it therefore does not deviate from it, otherwiſe their tangents would ſeparate, and would not both be at right angles with the lines touching the evolute. They muſt therefore coincide throughout.

8. The arches $b\,c\,d$ and $\beta\,\gamma\,\delta$, intercepted by the ſame radii B b and D d, may be called *concentric*; and the angles contained between the tangents drawn through their extremities are equal. Thus the angle $\lambda\,\tau\,\varepsilon$ is equal to $l\,p\,o$: but although equidiſtant, parallel, and containing the ſame angle between their tangents and between their radii, they are not ſimilar. Thus, the arch $\alpha\,\beta$ has a curvature at α that is the ſame with that of any circle whoſe radius is equal to A α; but the curvature at A is incomparable with it, and unmeaſurable. The ſame may be ſaid of the curvature δ at β and at B.

9. If a circle $u\,d\,z$ be deſcribed round the centre D with the radius D d, it both touches and cuts the evolutrix in the point d, and no circle can be deſcribed touching the curve in that point, and paſſing between it and the circle $u\,d\,z$; For ſince it touches the curve in d, its centre muſt be ſomewhere in the line d D perpendicular to $m\,d\,t$. It cannot be in any point n more remote from d than D is; for it would paſs without the arch $d\,u$, and be more remote than $d\,u$ from the arch $d\,c$ of the evolutrix. On the other ſide, it would indeed paſs without the arch $d\,z$, which lies within the arch $d\,e$ of the evolutrix: but it would alſo paſs without the curve. For it has been already demonſtrated (7) that $n\,d$ is greater than $n\,e$; and the curve would lie between it and the circle $d\,z$.

Thus it appears, that a circle deſcribed with the evolved radius approaches nearer to the curve, or touches it more cloſely, than any other circle; all other circles either interſect it in meaſurable angles, or are within or without the curve on both ſides of the point of contact. This circle $u\,d\,z$ has therefore the ſame curvature

ture with the curve in the point of contact and coalescence. It is the EQUICURVE CIRCLE, the circle of equal curvature, the OSCULATING CIRCLE (a name given it by Leibnitz). The evolved radius of the evolute is the RADIUS OF CURVATURE of the evolutrix, and the point of the evolute is the CENTRE OF CURVATURE at the point of contact with the evolutrix. The evolute is the geometrical locus of all the centres of curvature of the evolutrix.

This is the most important circumstance of the whole doctrine of the involution and evolution of curve lines. It is assumed as a self-evident truth by the precipitant writers of elements. It is indeed very like truth: For the extremity of the thread is a momentary radius during the process of evolution; and any minute arch of the evolute nearer the vertex must be conceived as more incurvated than the arch at the point of contact, because described with shorter radii: for the same reason, all beyond the contact must be less incurvated, by reason of the greater radii. The curvature at the contact must be neither greater nor less than that of the circle. But we thought it better to follow the example of Huyghens, and to establish this leading proposition on the strictest geometrical reasoning, acknowledging the singular obligation which mathematicians are under to him for giving them so palpable a method of fixing their notions on this subject. When the evolute of a curve is given, we have not only a clear view of the genesis of the curve, with a neat and accurate mechanical method of describing it, but also a distinct comprehension of the whole curvature, and a connected view of its gradual variations.

We speak of curvature that is greater and lesser; and every person has a general knowledge or conception of the difference, and will say, that an ellipsis is more curve at the extremities of the transverse axis than any where else. But before we can institute a comparison between them with a precision that leads to any thing, we must agree about a measure of curvature, and say what it is we mean by a double or a triple curvature.

Now there are two ways in which we may consider curvature, or a want of rectitude: We may call that a double curvature which, in a given space, carries us twice as far from the straight line; or we may call that a double curvature by which we deviate twice as much from the same direction. Both of these measures have been adopted; and if we would rigidly adhere to them, there would be no room for complaint: but mathematicians have not been steady in this respect, and by mixing and confounding these measures, have frequently puzzled their readers. All agree, however, in their first and simple measures of curvature, and say, that the curvature of an arch of a circle is as the arch directly, and as the radius inversely. This is plainly measuring curvature by the deflection from the first direction. In an arch of an inch long, there is twice as much deflection from the first direction when the radius of the circle is of half the length. If the radius is about $57\frac{1}{4}$th inches, an arch of one inch in length produces a final direction one degree different from the first. If the radius is $114\frac{1}{2}$ inches, the deviation is but half of a degree. The linear deflection from the straight path is also one-half. In the case of circles, therefore, both measures agree: but in by far the greatest number of cases they may differ exceedingly, and the change of direction may be greatest when the linear deviation is least. Flexure, or change of direction, is, in general, the most sensible and the most important character of curvature, and is understood to be its criterion in all cases. But our processes for discovering its quantity are generally by first discovering the linear deviation; and, in many cases, particularly in our philosophical inquiries, this linear deviation is our principal object. Hence it has happened, that the mathematician has frequently stopped short at this result, and has adapted his theorems chiefly to this determination. These differences of object have caused great confusion in the methods of considering curvature, and led to many disputes about its nature, and about the angle of contact; to which disputes there will be no end, till mathematicians have agreed in their manner of expressing the measures of curvature. At present we abide by the measure already given, and we mean to express by curvature or flexure the change of direction.

This being premised, we observe, that the curvature of all these curves of evolution where they separate from their evolutes, is incomparable with the curvature in any other place. In this point the radius has no magnitude; and therefore the curvature is said to be infinitely great. On the other hand, if the evolved curve has an assymptote, the curvature of the evolutrix of the adjacent branch is said to be infinitely small. These expressions becoming familiar, have occasioned some very intricate questions and erroneous notions. There can be little doubt of their impropriety: For when we say, that the curvature at A is infinitely greater than at α, we do not recollect that the flexure of the whole arch A l is equal to that of the whole arch $\alpha\,\beta$, and the flexure at A must either make a part of the whole flexure, or it must be something disparate.

The evolutrix A $b\,c\,d\,f$ (fig. 2.) of the common equilateral hyperbola exhibits every possible magnitude of curvature in a very small space. At the vertex A of the hyperbola it is perpendicular to the curve; and therefore has the transverse axis A φ A″ for its tangent. The curvature of the evolutrix at A is called infinitely great. As the thread unlaps from the branch ABC, its extremity describes A $b\,c$. It is plain, that the evolutrix must cut the assymptote φ H at right angles in some point G, where the curvature will be what is called infinitely small; because the centre of curvature has removed to an infinite distance along the branch AF of the hyperbola. This evolutrix may be continued to the vertex of the hyperbola on the other side of the assymptote, by causing the thread to lap upon it, in the same way that Mr Huyghens completed his cycloidal oscillation. Or we may form another evolutrix $\alpha\,\beta\,\gamma\,\delta\,\varphi\,\gamma'\,\delta'\,\beta'$ A″, by lengthening the thread from G to φ, the centre of the hyperbola, and supposing that, as soon as the curve A $\delta\,\varphi$ is completed, by unlapping the thread from the branch ABC, another thread laps upon the hyperbola A″ F″. This last is considered as a more geometrical evolution than the other: For the mathematicians, extending the doctrine of evolution beyond Mr Huyghens's restriction to curves which had their convexity turned one way, have agreed to consider as one continued evolution whatever will complete the curve expressed by one equation. Now the same equation expresses both the curves AF and A″F″, which occupy the same axis AA″. The cycloid employed by Huyghens

Involution. Huyghens is, in like manner, but one continuous curve, deſcribed by the continued provolution of the circle along the ſtraight line, although it appears as two branches of a *repeated* curve. We ſhall meet with many inſtances of this ſeemingly compounded evolution when treating of the ſecond queſtion.

Since the arch A b d G contains every magnitude of curvature, it appears that every kind of curvature may be produced by evolution. We can have no conception of a flexure that is greater than what we ſee at A, or leſs than what we ſee at G; yet there are caſes which ſeem to ſhew the contrary, and are familiarly ſaid, by the greateſt mathematicians, to exhibit curvatures infinitely ſmaller ſtill. Thus, let ABC (fig. 3.) be a conical parabola, whoſe parameter is AP. Let AEF be a cubical parabola, whoſe parameter is AQ. If we make AQ to AD as the cube of AP to the cube of AQ, the two parabolas will interſect each other in the ordinate DB. For, making AP $= p$, and AQ $= q$, and calling the ordinate of the conic parabola y, that of the cubic parabola z, and the indeterminate abſciſſa AD x, we have

$$p^3 : q^3 = q : x, = q^3 : z^3, \text{ and } p : q = q : z;$$

but $q : p = q : p$; therefore, by compoſition,

$$p^2 : q^2 = q^2 : px = q^2 : y^2, \text{ and } p : q = q : y;$$

therefore $z = y$, and the parabolas interſect in B.

Now, becauſe in all parabolas the ordinates drawn at the extremity of the parameters are equal to the parameters, the interſections q and p will be in a line A q p, which makes half a right angle with the axis AP. Therefore, when AQ is greater than AP, the point q is without the conical parabola, and the whole arch of the cubical parabola cut off by the ordinate DB is alſo without it: but when AQ is leſs than AP, q is within the conical parabola, as is alſo the arch q B. Therefore the remaining arch BEA is without it, and is therefore leſs incurvated at A. An endleſs number of conical parabolas of ſmaller curvature may be drawn by enlarging AP; yet there will ſtill be an arch AEB of the cubical parabola which is without it, and therefore leſs incurvated. Therefore the curvature of a cubical parabola is leſs than that of any conical parabola: It is ſaid to be infinitely leſs, becauſe an infinity of cubical parabolas of *ſmaller curvature* than AEB may be drawn by enlarging AQ.

It may be demonſtrated in the ſame manner, that a paraboloid, whoſe ordinates are in the ſubbiquadrate ratio of the abſciſſæ, has an infinitely ſmaller curvature at the vertex than the cubical parabola. And the curvature of the paraboloid of the next degree is infinitely leſs than this: and ſo on continually. Nay, Sir Iſaac Newton, who firſt took notice of this remarkable circumſtance, demonſtrates the ſame thing of an endleſs ſucceſſion of paraboloids interpoſed between any two degrees of this ſeries. *Neque novit* (ſays he) *natura limitem.*

If this be the caſe, all curves cannot be deſcribed by evolution; for we have no conception of a radius of curvature that is greater than a line without limit. The theory of curvilineal motions delivered in the article Dynamics muſt be imperfect, or there muſt be curve lines which bodies cannot deſcribe by any powers of nature. The theory there delivered profeſſes to teach how a body can be made to deſcribe the cubical parabola, and many other curves which have theſe infiniteſimal curvatures; and yet its demonſtrations employ the radius of curvature, and cannot proceed without it. We profeſs ourſelves obliged to an attentive reader (who has not favoured us with his name) for making this obſervation. It merits attention. Involution.

There muſt be ſome paralogiſm or miſconception in all this language of the mathematicians. It does not neceſſarily follow from the arch AEB lying without the arch AIB, that it is leſs incurvated at A; it may be more incurvated between A and B. Accordingly we ſee, that the tangent BT of the conical parabola is leſs inclined to the common tangent AV than the tangent B t of the cubical parabola is; and therefore the flexure of the whole arch AEB is greater than that of the whole arch AIB; and we ſhall ſee afterwards, that there is a part of AEB that is more incurvated than any part of AIB. There is nothing correſponding to this unmeaning and inconceivable ſucceſſion of ſerieſes of magnitudes of one kind, each of which contains an endleſs variety of individuals, and the greateſt of one ſeries infinitely leſs than the ſmalleſt of the next, &c.; there is nothing like this demonſtrated by all our arguments. In none of theſe do we ever treat of the curvature at A, But of a curvature which is *not* at A. At A we have none of the lines which are indiſpenſably neceſſary for the demonſtration. Beſides, in the very ſame manner that we can deſcribe a cubical parabola, and prove that it has an arch lying without the conical parabola, we can deſcribe a circle, and demonſtrate that it has alſo an arch lying without the parabola. Theſe infiniteſimal curvatures, therefore, are not warranted by our arguments, nor does it yet appear that there are curves which cannot be deſcribed by evolution. We are always puzzled when we ſpeak of infinites and infiniteſimals as of ſomething preciſe and determinate; whereas the very denomination precludes all determination. We take the diſtinguiſhing circumſtance of thoſe different orders for a thing clearly underſtood; for we build much on the diſtinction. We conceive the curvature of the cubical parabola as verging on that of the common parabola, and the one ſeries of curvatures as beginning where the other ends. But Newton has ſhewn, that between theſe two ſerieſes an endleſs number of ſimilar ſerieſes may be interpoſed. The very names given to the curvature at the extremities of the hyperbolic evolutrix have no conceptions annexed to them. At the vertex of the hyperbola there is no line, and at the interſection with the aſſymptote there is no curvature. Theſe unguarded expreſſions, therefore, ſhould not make us doubt whether all curves may be deſcribed by evolution. If a line be incurvated, it is not ſtraight. If ſo, two perpendiculars to it muſt diverge on one ſide, and muſt converge and meet on the other in ſome point. This point will lie between two other points, in which the two perpendiculars touch that curve by the evolution, of which the given arch of the curve may be deſcribed. Finally (which ſhould decide the queſtion), we ſhall ſee by and bye, that the cubic, and all higher orders of paraboloids, may be ſo deſcribed by evolution from curves having aſſymptotic branches of determinable forms.

Such are the general affections of lines generated by evolution. They are not, properly ſpeaking, peculiar properties; for the evolutrixes may be any curve lines whatever. They only ſerve to mark the mutual relations of the evolutes with their evolutrixes, and enable us to construct the one, and to discover its properties by means of our knowledge of the other. We proceed to shew how the properties of the evolutrix may be determined by our knowledge of the evolute.

This problem will not long occupy attention, being much limited by the conditions. One of the first is, that the length of the thread evolved must be known in every position: Therefore the length of the evolved arch must, in like manner, be known; and this, not only *in toto*, but every portion of it. Now this is not universally, or even generally the case. The length of a circular, parabolic, hyperbolic, arch has not yet been determined by any finite equation, or geometrical construction. Therefore their evolutrixes cannot be determined otherwise than by approximation, or by comparison with other magnitudes equally undetermined. Yet it sometimes happens, that a curve is discovered to evolve into another of known properties, although we have not previously discovered the length of the evolved arch. Such a discovery evidently brings along with it the rectification of the evolute. Of this we have an instance in the very evolution which gave occasion to the whole of this doctrine; namely, that of the cycloid; which we shall therefore take as our first example.

Let ABC (fig. 5.) be a cycloid, of which AD is the axis, and AHD the generating circle, and AG a tangent to the cycloid at A, and equal to DC. Let BKE touch the cycloid in B, and cut AG in K. It is required to find the situation of that point of the line BE which had unfolded from A?

Draw BH parallel to the base DC of the cycloid, cutting the generating circle in H, and join HA. Describe a circle KEM equal to the generating circle AHD, touching AG in K, and cutting BK in some point E. It is known, by the properties of the cycloid, that BK is equal and parallel to HA, and that BH is equal to the arch A *b* H. Because the circles AHD and KEM are equal, and the angles HAK and AKE are equal, the chords AH and KE cut off equal arches, and are themselves equal. Because BHAK is a parallelogram, AK is equal to HB; that is, to the arch A *b* H, that is, to the arch K *m* E. But if the circle KEM had been placed on A, and had rolled from A to K, the arch disengaged would have been equal to AK, and the point which was in contact with A would now be in E, in the circumference of a cycloid AEF, equal to CBA, having the line AG, equal and parallel to DC, for its base, and GF, equal and parallel to DA, for its axis. And if the diameter KM be drawn, and EM be joined, EM touches the cycloid AEF.

Cor. The arch BA of the cycloid is equal to twice the parallel chord HA of the generating circle: For this arch is equal to the evolved line BKE; and it has been shewn, that EK is equal to KB, and BE is therefore equal to twice BK, or to twice HA. This property had indeed been demonstrated before by Sir Christopher Wren, quite independent of the doctrine of evolution; but it is given here as a legitimate result of this doctrine, and an example of the use which may be made of it. Whenever a curve can be evolved into another which is susceptible of accurate determination, the arch of the evolved curve is determined in length; for it always makes a part of the thread whose extremity describes the evolutrix, and its length is found, by taking from the whole length of the thread that part which only touches the curve at its vertex.

This genesis of the cycloid AEF, by evolution of the cycloid ABC, also gives the most palpable and satisfactory determination of the area of the cycloid. For since BE is always parallel to AH, AH will sweep over the whole surface of the semicircle AHD, while BE sweeps over the whole space CBAEF; and since BE is always double of the simultaneous AH, the space CBAEF is quadruple of the semicircle AHD. But the space described in any moment by BK is also one fourth part of that described by BE. Therefore the area GAEF is three times the semicircle AHD; and the space DHABC is double of it; and the space CBAG is equal to it.

Sir Isaac Newton has extended this remarkable property of evolving into another curve of the same kind to the whole class of epicycloids, that is, cycloids formed by a point in the circumference of a circle, while the circle rolls on the circumference of another circle, either on the convex or concave side; and he has demonstrated, that they also may all be rectified, and a space assigned which is equal to their area (See *Principia*, B. I. prop. 48. &c.). He demonstrates, that the whole arch is to four times the diameter of the generating circle as the radius of the base is to the sum or difference of those of the base and the generating circle. We recommend these propositions to the attention of the young reader who wishes to form a good taste in mathematical researches; he will there see the geometrical principles of evolution elegantly exemplified.

We may just observe, before quitting this class of curves, that many writers, even of some eminence, in their compilations of elements, give a very faulty proof of the position of the tangent of a curve described by rolling. They say, for example, that the tangent of the cycloid at E is perpendicular to KE; because the line KE is, at the moment of description, turning round K as a momentary centre. This, to be sure, greatly shortens investigation; and the inference is a truth, not only when the rolling figure is a circle rolling on a straight line, but even when any one figure rolls on another. Every point of the rolling figure really *begins* to move perpendicularly to the line joining it with the point of contact. But this genesis of the arch E *e*, by the evolution of the arch B *b*, shews that K is by no means the centre of motion, nor HK the radius of curvature. Nor is it, in the case of epicycloids, trochoids, and many curves of this kind, a very easy matter to find the momentary centre. The circle KEM is both advancing and turning round its centre; and these two motions are equal, because the circle does not slide but roll, the detached arch being always equal to the portion of the base which it quits. Therefore, drawing the tangents E *g*, M *g*, and completing the parallelogram E *f* M *g*, E *f* will represent the progressive motion of the centre, and E *g* the motion of rotation. EM, the motion compounded of these, must be perpendicular to the chord EK.

The investigation that we have given of the evolutrix of the cycloid has been somewhat peculiar, being that which offered itself to Mr Huyghens at the time when he and many other eminent mathematicians were much occupied with the singular properties of this curve. It does not serve, however, so well for exemplifying the general

general process. For this purpose, it is proper to avail ourselves of all that we know of the cycloid, and particularly the equality of its arch BA to the double of the parallel chord HA. This being known, nothing can be more simple than the determination of the evolutrix, either by availing ourselves of every property of the cycloid, or by adhering to the general process of referring every point to an abscissa by means of perpendicular ordinates. In the first method, knowing that BE is double of BK, and therefore KE equal to HA, and KA = BH, = H *b* A, = K *m* E, we find E to be the describing point of the circle, which has rolled from A to K. In the other method, we must draw EN perpendicular to AG; then, because the point E moves, during evolution, at right angles to BE, EK is the normal to the curve described, and NK the subnormal, and is equal to the corresponding ordinate H′ I′ of the generating circle of the cycloid ABC. This being a characteristic property of a cycloid, E is a point in the circumference of a cycloid equal to the cycloid ABC.

Or, lastly, in accommodation to cases where we are supposed to know few of the properties of the evolute, or, at least, not to attend to them, we may make use of the fluxionary equation of the evolute to obtain the fluxionary equation of the evolutrix. For this purpose, take a point *e* very near to E, and draw the evolving radius *be*, cutting E*f* (drawn parallel to the base DC) in *o*; draw *en* parallel to the axis of the evolute, cutting E*o* in *v*; also draw *bbi* parallel to the base, and B*d* perpendicular to it. If both curves be now referred to the same axis CGF, it is plain that B*b*, B*d*, and *db* are ultimately as the fluxions of the arch, abscis, and ordinate of the evolute, and that E*e*, *ev*, and *v*E, are ultimately as the fluxions of the arch, abscissa, and ordinate of the evolutrix. Also the two fluxionary triangles are similar, the sides of the one being perpendicular, respectively, to those of the other. If both are referred to one axis, or to parallel axes, the fluxion of the abscissa of the evolute is to that of its ordinate, as the fluxion of the ordinate of the evolutrix is to that of its abscissa. Thus, from the fluxionary equation of the one, that of the other may be obtained. In the present case, they may be referred to AD and FG, making CG equal to the cycloidal arch CBA. Call this *a*; AI, *x*; IB, *y*; and AB, or EB, *z*. In like manner, let F*t* be $= u$, *t*E $= v$, and FE $= w$; then, because $DH^2 = DA^2 - AH^2$, and DA and AH are the halves of CF and BE, we have $DH^2 = \frac{a^2 - z^2}{4}$. Also $DI = \frac{DH^2}{DA} = \frac{a^2 - z^2}{4 \times \frac{1}{2}a}, = \frac{a^2 - z^2}{2a}$. But DI = F*t*. Therefore F*t*, or $u, = \frac{a^2 - z^2}{2a}$. Also $\dot{w} = \frac{\dot{u}z}{y}$, by what was said above, that is, $\dot{w} = \frac{a\dot{u}}{\sqrt{a^2 - z^2}}, = \frac{a\dot{u}}{\sqrt{2au}}$. Therefore we have $\dot{w} : \dot{u}\ (= a : \sqrt{2au}) = \sqrt{\tfrac{1}{2}a} : \sqrt{u} = \sqrt{GF} : \sqrt{Ft}$, which is the analogy competent to a cycloid whose axis is GF = DA.

It is not necessary to insist longer on this in this place; because all these things will come more naturally before us when we are employed in deducing the evolute from its evolutrix.

When the ordinates of a curve converge to a centre, in which case it is called a radiated curve, it is most convenient to consider its evolutrix in the same way, conceiving the ordinates of both as insisting on the circumference of a circle described round the same centre. Spirals evolve into other spirals, and exhibit several properties which afford agreeable occupation to the curious geometer. The equiangular, logarithmic, or loxodromic spiral, is a very remarkable example. Like the cycloid, it evolves into another equal and similar equiangular spiral, and is itself the evolutrix of a third. This is evident on the slightest inspection. Let C *r q p* (fig. 6.) be an equiangular spiral, of which S is the centre; if a radius SC be drawn to any point C, and another radius SP be drawn at right angles to it, the intercepted tangent CP is known to be equal to the whole length of the interior revolutions of the spiral, though infinite in number. If the thread CP be now unlapped from the arch C *r q*, it is plain that the first motion of the point P is in a direction PT, which is perpendicular to PC, and therefore cuts the radius PS in an angle SPT, equal to the angle SCP; and, since this is the case in every position of the point, it is manifest that its path must be a spiral PQR, cutting the radii in the same angle as the spiral C *r q p*. James Bernoulli first discovered this remarkable property. He also remarked, that if a line PH be drawn from every point of the spiral, making an angle with the tangent equal to that made by the radius (like an angle of reflection corresponding with the incident ray SP), those reflected rays would all be tangents to another similar and equal spiral I *v* H: so that PH = PS. S and H are conjugate foci of an infinitely slender pencil; and therefore the spiral I *v* H is the caustic by reflection of RQP for rays flowing from S. If another equal and similar spiral *x v y* roll on I *v* H, its centre *z* will describe the same spiral in another position *w u z*. All these things flow from the principles of evolution alone: and Mr Bernoulli traces, with great ingenuity, the connection and dependence of caustics, both by reflection and refraction, of cycloidal, and all curves of provolution, and their origin in evolution or involution. A variety of such repetitions of this curve (and many other singular properties), made him call it the SPIRA MIRABILIS. He desired that it should be engraved on his tombstone, with the inscription EADEM MUTATA RESURGO, as expressive of the resurrection of the dead. See his two excellent dissertations in *Act.* Erudit. 1692, March and May.

Another remarkable property of this spiral is, that if, instead of the thread evolving from the spiral, the spiral evolve from the straight line PC, the centre S will describe the straight line PS. Of this we have an example in the apparatus exhibited in courses of experimental philosophy, in which a double cone descends, by rolling along two rulers inclined in an angle to each other (see *Gravesande's* Nat. Phil. I. § 210). It is pretty remarkable, that a rolling motion, seemingly round C, as a momentary centre, should produce a motion in the straight line SP: and it shews the inconclusiveness of the reasoning, by which many compilers of elements of geometry profess to demonstrate, that the motion of the describing point S is perpendicular to the momentary radius. For here, although this seeming momentary radius may be shorter than any line that can be named, the real radius of curvature is longer than any line that can be named.

But it is not merely an object of speculative geometric curiosity to mark the intimate relation between the genesis of curves by evolution and provolution; it may be applied to important purposes both in science and in art. Mr M'Laurin has given a very inviting example of this in his account of the Newtonian philosophy; where he exhibits the moon's path in absolute space, and from this proposes to investigate the deflecting forces, and *vice versa*. We have examples of it in the arts, in the formation of the pallets of pendulums, the teeth of wheels, and a remarkable one in Messrs Watt and Boulton's ingenious contrivance for producing the rectilineal motion of a piston rod by the combination of circular motions. M. de la Hire, of the Academy of Sciences at Paris, has been at great pains to shew how all motions of evolution may be converted into motions of provolution, in a memoir in 1706. But he would have done a real service, if, instead of this ingenious whim, he had shewn how all motions of provolution may be traced up to the evolution which is equivalent to them. For there is no organic genesis of a curvilineal motion so simple as the evolution of a thread from a curve. It is the primitive genesis of a circle; and it is in evolution alone that any curvilineal motion is comparable with circular motion. A given curve line is an individual, and therefore its primitive organical genesis must also be individual. This is strictly true of evolution. A parabola has but one evolute. But there are infinite motions of provolution which will describe a parabola, or any curve line whatever; therefore these are not primitive organical modes of description. That this, however, is the case, may be very easily shewn. Thus let ABCD (fig. 7.) be a parabola, or any curve; and let *a b c d* be any other curve whatever. A figure E *m l k h i* may be found such, that while it rolls along the curve *a b c d*, a point in it shall describe the parabola. The process is as follows: Let B *b*, C *c*, D *d*, &c. be a number of perpendiculars to the parabola, cutting the curve *a b c d* in so many points. The perpendiculars may be so disposed that the points *a*, *b*, *c*, &c. shall be equidistant. Now we can construct a triangle E *c h* so, that the three sides E *e*, *eh*, and *h* E, shall be respectively equal to the three lines E *e*, *ef*, F *f*. In like manner may the whole figure be constructed, having the little bases of the triangles respectively equal to the successive portions of the base A *b c d*, and the radii equal to the perpendiculars B *b*, C *c*, D *d*, &c. Let this figure roll on this base *c*. While the little side *e k* moves from its present position, and applies itself to *e f*, the point E describes an arch E *ε* of a circle round the centre *e*, and, falling within the parabola, is somewhere between E and F. Then continuing the provolution, while the next side *h i* turns round *f* till *i* applies to *g*, the point E describes another arch *ε* F *o* round *f*, first rising up and reaching the parabola in F, when the line *h* E coincides with *f* F, and then falling within the parabola till the point *h* begin to rise again from *f* by the turning of the rolling figure round the point *g*. Reversing the motion, the sides *i h*, *h e*, *e k*, &c. apply themselves in succession to the portions *g f*, *f e*, *e d*, &c. of the base, and the point E describes an undulating line, consisting of arches of circles round the successive centres *g*, *f*, *e*, &c. These circular arches all touch the parabola in the points G, F, E, &c. and separate from it a little internally. By diminishing the portions of the base, and increasing the number of the triangular elements of the rolling figure without end, it is evident that the figure becomes ultimately curvilineal instead of polygonal, and the point E continues in the parabola, and accurately describes it. It is now a curvilineal figure, having its elementary arches equal to the portions of the base to which they apply in succession, and the radii converging to E equal to the perpendiculars intercepted between the curve ABCD and the base. It may therefore be accurately constructed.

It is clear, that practical mechanics may derive great advantage from a careful study of this subject. We now see motions executed by machinery which imitate almost every animal motion. But these have been the result of many random trials of *wipers*, *snail-pieces*, &c. of various kinds, repeatedly corrected, till the desired motion is at last accomplished. But it is, as we see, a scientific problem, to construct a figure which shall certainly produce the proposed motion; nor is the process by any means difficult. But how simple, in comparison, is the production of this motion by evolution. We have only to find the curve line which is touched by all the perpendiculars B *b*, C *c*, D *d*, &c. This naturally leads us to the second problem in this doctrine, namely, to determine the evolute by our knowledge of the involute: a problem of greater difficulty and of greater importance, as it implies, and indeed teaches, the curvature of lines, its measure, and the law of its variation in all particular cases. The evolute of a curve is the geometrical expression, and exhibition to the eye, of both these affections of curve lines.

Since the evolved thread is always at right angles to the evolutrix and its tangent, and is itself always a tangent of the evolute, it follows, that all lines drawn perpendicular to the arch of any curve, touch the curve line which will generate the given curve by evolution. Were this evolved curve previously known to us, we could tell the precise point where every perpendicular would touch it; but this being unknown, we must determine the points of contact by some other method, and by this determination we ascertain so many points of the evolute. The method pursued is this: When two perpendiculars to the proposed curve are not parallel (which we know from the known position of the tangents of our curve), they must intersect each other somewhere on that side of the tangents where they contain an angle less than 180°. But when they thus intersect, one of them has already touched the evolute, and the other has not yet reached it. Thus let *b s*, *e s* (fig. 1.) be the two perpendiculars: being tangents to the evolute, the point *s* of their intersection must be on its convex side, and the unknown points of contact B and E must be on different sides of *s*. These are elementary truths.

Let *e* E approach toward *b* B, and now cut it in *x*. The contact has shifted from E to D, and *x* is still between the contacts. When the shifting perpendicular comes to the position *c* C, the intersection is at *i*, between the contacts B and C. And thus we see, that as the perpendiculars to the involute gradually approach, their contacts with the evolute also approach, and their intersection is always between them. Hence it legitimately follows, that the ultimate position of the intersection fection (which alone is fufceptible of determination by the properties of the involute) is the pofition of the point of contact, and therefore determines a point of the evolute. The problem is therefore reduced to the inveftigation of this ultimate interfection of two perpendiculars to the propofed curve, when they coalefce after gradually approaching. This will be beft illuftrated by an example: Therefore let ABC (fig. 8.) be a parabola, of which A is the vertex, AH the axis, and AV one-half of the parameter; let BE and CK be two perpendiculars to the curve, cutting the axis in E and K, and interfecting each other in r; draw the ordinates BD, CV, and the tangent BT, and draw BF parallel to the axis, cutting CK in F, and CN in O.

Becaufe the perpendiculars interfect in r, we have $rE : EB = EK : BF$. If therefore we can difcover the ratio of EK to BF, we determine the interfection r. But the ratio of EK to BF is compounded of the ratio of EK to BO, and the ratio of BO to BF. The firft of thefe is the ratio of equality; for DE and VK are, each of them, equal to AV, or half the parameter. Take away the common part VE, and the remainders EK and DV are equal, and DV is equal to BO; therefore $EK : BF = BO : BF$; therefore $rE : rB = BO : BF$, and (by divifion) $BE : Er = FO : OB$. Now let the point C continually approach to B, and at laft unite with it. The interfection r will unite with a point of contact N on the evolute. The ultimate ratio of FO to OB, or of $fo : oB$, is evidently that of ED to DT, or ED to 2DA: therefore $BE : EN = ED : 2DA$, or as half the parameter to twice the abfciffa. Thus have we determined a point of the evolute; and we may, in like manner, determine as many as we pleafe.

But we wifh to give a general character of this evolute, by referring it to an axis by perpendicular ordinates. It is plain that V is one point of it, becaufe the point E is always diftant from its ordinate DB by a line equal to AV; and therefore, when B is in A, E will be in V, and r will coincide with it. Now draw VP and NQ perpendicular to AH, and NM perpendicular to VP; let EB cut PV in t: then, becaufe AV and DE are equal, AD is equal to VE, and VE is equal to one half of DT. Moreover, becaufe BD and NQ are parallel, $DE : EQ = BE : EN = DE : DT$; therefore $DT = EQ$, and $VE = \frac{1}{2}EQ$, and therefore $= \frac{1}{3}VQ$; therefore Vt is $\frac{1}{3}$ of Mt, and $\frac{1}{2}MV$. This is a characteriftic property of the evolute. The fubtangent is $\frac{3}{2}$ of the abfciffa; in like manner, as in the common parabola, it is double of the abfciffa. We know therefore that the evolute is a paraboloid, whofe equation is $ax^2 = y^3$; that is, the cube of any ordinate MN is equal to the parallelopiped whofe bafe is the fquare of the abfciffa VM, and altitude a certain line VP, called the parameter. To find VP, let CR be the perpendicular to the parabola in the point where it is cut by the ordinate at V; draw the ordinate RS of the paraboloid, and RG perpendicular to AH. Then it is evident, from what has been already demonftrated, that VK is $\frac{1}{2}$ of KG, and $\frac{1}{3}$ of VG: therefore $KG^2 = 4VK^2$, and (in the parabola) $VC^2 = 2VK^2$. Alfo, becaufe $KV : VC = KG : GR$, we have $GR^2 = 2KG^2 = 8VK^2$; therefore $VP \times RG^2 = 8VP \times VK^2$. But $VG^3 = 27VK^3, = 27VK \times VK^2$: therefore, becaufe in the paraboloid $VP \times VS^2, = SR^3$, or $VP \times RG^2 = VG^3$, we have $8VP \times VK^2 = 27VK \times VK^2$, and $8VP = 27VK$; or VK : VP; that is, $AV : VP = 8 : 27$; or $VP = \frac{27}{8}AV$, or $\frac{27}{16}$ of the parameter of the parabola ABC. The evolute of the conical parabola is the curve called the femicubical parabola, and its parameter is $\frac{27}{16}$ of the conical parabola.

This inveftigation is nearly the fame with that given by Huyghens, which we prefer at prefent to the method generally employed, becaufe it keeps the principle of inference more clofely in view.

Mr Huyghens has deduced a beautiful corollary from it. Since the parabola ABC is defcribed by the evolution of the paraboloid VNR, the line RC is equal to the whole evolved arch RNV, together with the redundant tangent line AV. If therefore we take from CR a part Cx equal to the redundant AV, the remainder xR is equal to the arch RNV of the paraboloid. We may do this for every pofition of the evolved radius, and thus obtain a feries of points V, β, x, δ, ι, of the evolutrix of the paraboloid. We have even an eafier method for obtaining the length of any part of the arch of the paraboloid, without the previous defcription of the parabola ABC. Suppofe Py the arch of the paraboloid, and yz the tangent; make $Pz = \frac{2}{27}$ of the parameter, and defcribe the arch Puu of a circle; then draw from every tangent yz a parallel line xv, cutting the circle in v. The length of the arch yP is equal to $yz + uv$. The celebrated author congratulates himfelf, with great juftice, on this neat exhibition of a right line equal to the arch of a curve, without the employment of any line higher than the circle. It is the fecond curve that has been fo rectified, the cycloid alone having been rectified by plain geometry a very few years before by Sir Chriftopher Wren. It is very true, and he candidly admits it, that this very curve had been rectified before by Mr William Neill, a young gentleman of Oxford, and favourite pupil of Dr Wallis; as alfo by Mr Van Heuraet, a Dutch gentleman of rank, and an eminent mathematician. But both of thefe gentlemen had done it by means of the quadrature of a curve, conftructed from the paraboloid after the manner of Dr Barrow, *Lect. Geom.* XI. Nor was this a folitary difcovery in the hands of Mr Huyghens, as the rectification of the cycloid had been in thofe of Sir Chriftopher Wren; for the method of inveftigation furnifhed Mr Huyghens with a general rule, by which he could evolve every fpecies of paraboloid and hyperboloid, two claffes of curves which come in the way in almoft every difcuffion in the higher geometry. He obferves, that the ratio of Bf to Ee, being always compounded of the ratios of Bf to Bo, and of Bo, or Dd, to Ee; and the ultimate ratio of Bf to Bo being that of TE to TD, which is given by the nature of the paraboloid, we can always find the ratio of BE to BN, if we know that of Dd to Ee. In all curves, the ratio of Dd to Ee (taken indefinitely near), is that of the fubtangent to the fum of the fubtangent and ordinate of a curve conftructed on the fame abfciffa, having its ordinates equal to the fubnormals DE, de, VK, &c. In the conic fections the ratio is conftant, becaufe the line fo conftructed is a ftraight line; and, in the parabola, it is parallel to the axis. See farther properties of it in Barrow's *Lect. Geom.* XI.

From this inveftigation, Mr Huyghens has deduced the following beautiful theorem:

Let

Let a be the parameter of the paraboloid, x its abſciſſa, and y its ordinate; and let the equation be $a^m x^n = y^{m+n}$; let the radius of the evolute meet the tangent through the vertex A in Z. We ſhall always have $BN = \frac{n}{m} BE + \frac{m+n}{m} BZ$. Thus,

$$\left.\begin{array}{l} \text{If } a\,x = y^2 \\ a^2 x = y^3 \\ a\,x^2 = y^3 \\ a\,x^3 = y^4 \\ a^3 x = y^4 \\ \text{\&c.} \end{array}\right\} \text{then } BN = \left\{\begin{array}{l} BE + 2\,BZ \\ \frac{1}{2} BE + \frac{3}{2} BZ \\ 2\,BE + 3\,BZ \\ 3\,BE + 4\,BZ \\ \frac{1}{3} BE + \frac{4}{3} BZ. \\ \text{\&c.} \end{array}\right.$$

This is an extremely ſimple and perſpicuous method of determining the radius of the evolute, or radius of curvature; and it, at the ſame time, gives us the rectification of many curves. It is plain that every geometrical curve may be thus examined, becauſe the ſubnormals DE, VK are determined; and therefore their differences are determined. Theſe differences are the ſame with the differences of D d and E e; and therefore the ratio of D d to E e is determined; that is, the ſubſidiary curve now mentioned can always be conſtructed.

There is a ſingular reſult from this rule, which would hardly have been noticed, if the common method for determining BN had alone been employed. The equation of the paraboloid is ſo ſimple, that the increaſe of the ordinates and diminution of curvature ſeem to keep pace together; yet we have ſeen that, in the vertex of the cubical parabola, the curvature is leſs than any circular curvature that can be named. In the legs, the curvature certainly diminiſhes as they extend farther; there muſt therefore be ſome intermediate point where the curvature is the greateſt poſſible. This is diſtinctly pointed out by Mr Huyghens's theorem. The evolute of this paraboloid (having $a^2 x = y^3$) is a curve ONRNQ (fig. 9.) conſiſting of two branches RO, and RQ, which have a common tangent in R; the branch RQ has the axis AE for its aſſymptote. The thread unfolding from OR, its extremity, deſcribes the arch BC, and then, unfolding from RQ, it deſcribes the ſmall arch CB′A. When B′ is extremely near A, the thread has a poſition B′N′E, in which B′N is very nearly $\frac{1}{2}$BE. At C, if CE be biſected in G, GR is $\frac{1}{2}$ of CZ. Here CR the radius of curvature is the ſhorteſt poſſible. The evolutes of all paraboloids conſiſt of two ſuch branches, if $m + n$ exceeds 2.

Such is the theory of evolution and involution as delivered by Mr Huyghens about the year 1672. It was cultivated by the geometers with ſucceſs. Newton prized it highly, and gave a beautiful ſpecimen of its application to the deſcription, rectification, and quadrature of epicycloids, trochoids, and epicycles of all kinds. But it was eclipſed by the fluxionary geometry of Newton, which included this whole theory in one propoſition, virtually the ſame with Mr Huyghens's, but more comprehenſive in its expreſſion, and much more ſimple in its application. Adopting the unqueſtionable principle of Mr Huyghens, that the evolved thread is the radius of a circle which has the ſame flexures with the curve, the point of the evolute will be obtained by finding the length of the radius of the equicurve circle. The formula for this purpoſe is given in the article FLUXIONS of the *Encyclopædia*; but is incorrectly ſtated $= \frac{\overline{a+4}|^{\frac{3}{2}}}{2\sqrt{a}}$, inſtead of $\frac{\overline{a+4x}|^{\frac{1}{2}}}{2\sqrt{a}}$. The theorem alſo from which it is deduced $\left(r = \frac{\dot{z}^2}{-\dot{x}\ddot{y}}\right)$ is incorectly printed, and is given without any demonſtration, thereby becoming of very little ſervice to the reader. For which reaſon, it is neceſſary to ſupply the defect in this place.

Therefore let A b c d E f (fig. 10.) be a circle, of which C is the centre, and ACE a diameter; let the points b, c, d, of the circumference be referred to this diameter by the equidiſtant perpendicular ordinates $b\,i$, $c\,g$, $d\,k$; draw the chords $b\,c$, $c\,d$, producing $d\,c$ till it meet the ordinate $b\,i$ in a, produce $c\,g$ to the circle in f, and join $b\,f$, $d\,f$; draw $b\,h$, $c\,m$, perpendicular to the ordinates; then $b\,h$, $c\,m$, $h\,c$, $m\,d$, $b\,c$, $c\,d$, are ultimately proportional to the firſt fluxions of the abſciſſa AE, the ordinate $c\,g$, and the arch A c; alſo $a\,b$, the difference between $d\,m$ and $c\,h$ is ultimately as the ſecond fluxion of the ordinate. The triangle $a\,b\,c$ is ſimilar to $b\,d\,f$; for the angle $a\,b\,c$ is equal to the alternate angle $b\,c\,f$, which is equal to $b\,d\,f$, ſtanding on the ſame ſegment. The angle $a\,c\,b$ is equal to $b\,f\,d$, ſtanding on the ſegment $b\,c\,d$; therefore the remaining angles $b\,a\,c$ and $d\,b\,f$ are equal; therefore $a\,b : b\,c = b\,d : d\,f = \frac{1}{2}\,b\,d : \frac{1}{2}\,d\,f$. Now let the ordinates $b\,i$ and $d\,k$ continually approach the ordinate $c\,g$, and at laſt unite with it; we ſhall then have $b\,c$ ultimately equal to $\frac{1}{2}\,b\,d$, and $c\,g$ ultimately equal to $\frac{1}{2}\,d\,f$. Therefore, ultimately, $a\,b : b\,c = b\,c : c\,g$, and $c\,g = \frac{b\,c^2}{a\,b}$.

Let u, v, w, repreſent the variable abſciſſa, ordinate, and arch. We have, for the fluxionary expreſſion of the ordinate of the equicurve circle, $v = \frac{\dot{w}^2}{-\ddot{v}}$ ($\ddot{v}$ muſt have the negative ſign, becauſe, as the arch increaſes, $\dot{v}$ diminiſhes). In the next place, it is evident that, ultimately, $b\,h : b\,c = c\,g : c\,C$, and $c\,C = \frac{c\,g \times b\,c}{b\,h}$. If r be the radius of the equicurve circle, we have $\dot{u} : \dot{w} = v : r$, and $r = \frac{v\,\dot{w}}{\dot{u}}$. But we had $v = \frac{\dot{w}^2}{-\ddot{v}}$. Subſtitute this in the preſent equation, and we obtain $r = \frac{\dot{w}^3}{-\dot{u}\,\ddot{v}}$. Laſtly, obſerve that $\dot{w}^2 = \dot{u}^2 + \dot{v}^2$, and $\dot{w} = \sqrt{\dot{u}^2 + \dot{v}^2} = \overline{\dot{u}^2 + \dot{v}^2}|^{\frac{1}{2}}$. Therefore $\dot{w}^3 = \overline{\dot{u}^2 + \dot{v}^2}|^{\frac{3}{2}}$ and we have $r = \frac{\overline{\dot{u}^2 + \dot{v}^2}|^{\frac{3}{2}}}{-\dot{u}\,\ddot{v}}$, as the moſt general fluxionary expreſſion of the radius of a circle, in terms of the ſine, coſine, and arch.

When a curve and a circle have the ſame curvature, it is not enough that the firſt fluxions of their abſciſſæ, ordinates, and arches, are the ſame. This would only indicate the poſition of their common tangent. They muſt have the ſame deflection from that tangent. This is always equal to half of the ſecond fluxion of the ordinate. Therefore the circle and curve muſt have the ſame

ſame ſecond fluxion of their ordinates. Therefore let D b c d F be any curve coinciding with, or oſculated by, the circle A b c d. Let its axis be DG, parallel to the diameter AE; and let $c\,n$ be its ordinate. Let D n be $= x$, $c\,n = y$, and $b\,c = z$. We have $\dot x, \dot y, \dot z$, reſpectively equal to $\dot u, \dot v, \dot w$. Therefore the radius of the oſculating circle is $r = \frac{\dot z^3}{-\dot x \ddot y}$ or $r = \frac{\overline{\dot x^2 + \dot y^2}|^{\frac{3}{2}}}{-\dot x \ddot y}$, for all curves whatever. (We recommend the careful peruſal of the celebrated 2d corollary of the 10th propoſition of the 2d book of Newton's Principia, where the firſt principles of this doctrine are laid down with great acuteneſs.)

Inſtead of ſuppoſing the ordinates equidiſtant, and conſequently $\dot x$ invariable, we might have ſuppoſed the ordinates to increaſe by equal ſteps. In this caſe y would have had no ſecond fluxion. The radius would then be $= \frac{\dot z^3}{\dot y \ddot x}$. Or, laſtly, we might ſuppoſe (and this is very uſual) the arch z to increaſe uniformly. In this caſe $r = \frac{\dot z \dot y}{\ddot x}$: For becauſe $\dot x^2 + \dot y^2 = \dot z^2$, by taking the fluxion of it, $2\dot x \ddot x + 2\dot y \ddot y = 0$, and $\ddot y = \frac{\dot x \ddot x}{\dot y}$; and therefore $r = \frac{\dot z^3}{\dot y \ddot x - \dot x \ddot y}, = \frac{\dot z^3}{\dot y \ddot x + \frac{\dot x^2 \ddot x}{\dot y}}$ $= \frac{\dot y \dot z^3}{\dot y^2 + \dot x^2 \times \ddot x}, = \frac{\dot y \dot z}{\ddot x}$.

Having thus obtained the radius of curvature, and conſequently a point of the evolute, we determine its form by reference to an abſciſs, without much farther trouble: It only requires the drawing C p perpendicular to the axis of the propoſed curve, and giving the values of Cp and Dp. If we ſuppoſe $\dot x$ conſtant, then, cC being $= \frac{\dot z^3}{-\dot x \ddot y}$, we have D p (= D n + $g\,c$, = D n + $\frac{\dot y}{\dot z} \times c$C) $= x + \frac{\dot y \dot z^2}{-\dot x \ddot y}$; and p C (= $c\,g$ — $c\,n$, = $\frac{\dot x}{\dot z} \times c$C — $c\,n$) $= \frac{\dot z^2}{-\ddot y} - y$. But if we ſuppoſe $\dot y$ conſtant; then, c C being $= \frac{\dot z^3}{\dot y \ddot x}$, we have D$p = x + \frac{\dot z^2}{\ddot x}$, and pC $= \frac{\dot z \dot x^2}{\dot y \ddot x} - y$. And if $\dot z$ be conſtant, then, c C being $= \frac{\dot y \dot z}{\ddot x}$, we ſhall have D$p$ $= x + \frac{\dot y^2}{\ddot x}$, and pC $= \frac{\dot x \dot y}{\ddot x} - y$.

Theſe formulæ are ſo many general expreſſions for determining both the curvature of the propoſed curve and the form of its evolute. They alſo give us the rectification of the evolute; becauſe c C is equal to the evolved arch, or to that arch, together with a conſtant part, which was a tangent to the evolute at its vertex, in thoſe caſes where the involute has a finite curvature at its vertex; as in the common parabola.

Let us take the example of the common parabola, that we may compare the two methods. The equation of this is $a\,x = y^2$, or $a^{\frac{1}{2}} x^{\frac{1}{2}} = y$. This gives $\dot y$ $= \frac{1}{2} a^{\frac{1}{2}} \dot x\, x^{-\frac{1}{2}}, = \frac{a^{\frac{1}{2}} \dot x}{2\,x^{\frac{1}{2}}}$, and (making $\dot x$ conſtant) $\ddot y = -\frac{1}{2} \times \frac{1}{2} a^{\frac{1}{2}} \dot x^2 x^{-\frac{3}{2}} = \frac{-a^{\frac{1}{2}} \dot x^2}{4\,x^{\frac{3}{2}}}$. Wherefore $\dot z\ (= \sqrt{\dot x^2 + \dot y^2}) = \frac{\dot x}{2} \sqrt{\frac{4x + a}{x}}$, and the radius of curvature $\left(= \frac{\dot z^3}{-\dot x \ddot y} \right) = \frac{\overline{a + 4x}|^{\frac{3}{2}}}{2\sqrt{a}}$. At the vertex, where $x = 0$, the formula becomes $= \frac{1}{2} a$. Again, D p $\left(= x + \frac{\dot y \dot z^2}{-\dot x \ddot y} \right)$ becomes $\frac{1}{2} a + 3x$; and therefore V$p = 3x$, = the abſciſſa of our evolute. Likewiſe $c\,p$, its ordinate, $\left(= \frac{\dot z^2}{-\ddot y} - y \right)$ $= \frac{4x^{\frac{3}{2}}}{\sqrt{a}}$; and C$p^2 = \frac{16x^3}{a}$; and C$p^2 \times a = 16x^3$. But V$p = 3x$, and V$p^3 = 27x^3$. Therefore C$p^2 \times$ $\frac{1}{16}$th $a = x^3$, = $\frac{1}{27}$th Vp^3, and $\frac{27}{16}$ths $a \times$ Cp^2 = Vp^3. Therefore the evolute VC is a ſemicubical parabola, whoſe parameter is $\frac{27}{16}$ a, as was ſhewn by Mr Huyghens. The arch VC is $= \frac{\overline{a + 4x}|^{\frac{3}{2}}}{2\sqrt{a}} - \frac{1}{2} a$.

We ſhall give one other example, which comprehends the whole claſs of paraboloids. Their general equation is $y = a\,x^n$. This gives us $\dot y = n\,a\,x^{n-1} \dot x$, and $\ddot y = n \times \overline{n-1} \times a\,x^{n-2} \dot x^2$; therefore $\dot z$ (= $\sqrt{\dot x^2 + \dot y^2}$) $= \dot x \sqrt{1 + n^2 a^2 x^{2n-2}}$; C$c$ $\left(= \frac{\dot z^3}{-\dot x \ddot y} \right)$ $= \frac{\overline{1 + n^2 a^2 x^{2n-2}}|^{\frac{3}{2}}}{-n \times \overline{n-1} \times a\,x^{n-2}}$; D$p$ $\left(= x + \frac{\dot y \dot z^2}{-\ddot y \dot x} \right)$ $= x - \frac{x + n^2 a^2 x^{2n-1}}{n-1}$; C$p$ $\left(= \frac{\dot z^2}{-\ddot y} - y \right) =$ $\frac{1 + \overline{2n-1} \times n^2 a^2 x^{2n-2}}{-\overline{n-1} \times n\,a\,x^{n-2}}$; and DV $= -\frac{n^2 a^2 0^{2n-1}}{n-1}$.

This laſt formula expreſſes the radius of curvature at the vertex D, or the redundant part of the thread, by which it exceeds the arch VC of the evolute. If $n = \frac{1}{2}$, the formula becomes $\frac{a^2}{2}$; but if n be greater than this, VC will be $= 0$; and if it be leſs, VC will be infinite. Hence it appears, that the radius of curvature at the vertex of a curve is a finite quantity only in the caſes where the firſt or naſcent ordinates are in the ſubduplicate ratio of their abſciſſæ. In all other caſes, the curvature is incomparable with that of any circle, being either what is called infinite (when n is greater than $\frac{1}{2}$) or nothing (when it is leſs).

We ſcruple not to ſay, that the method of Mr Huyghens is more luminous, more pleaſing to the imagination of a geometer, than this; and in all the caſes which occurred to us in our employment of it, it ſuggeſted

gested more ready constructions, with the additional satisfaction of exhibiting, in a continuous train, what the *symbolical* method, proceeding by the fluxionary calculus, only indicates by points. We must also observe, that the subsidiary curve employed by Huyghens, having its ordinates equal to the subnormals of the involute under examination, is the geometrical expression of that function of the involute which gives the second fluxions $\ddot{y}$ and $\ddot{x}$ of the ordinate and abscissa. The young mathematician will find no difficulty in constructing this curve *in every case;* whereas we imagine that he will not find it a light matter to construct the final equations of the symbolic method *almost in any case*. At the same time, the all comprehending extent of the latter method, and the numberless general theorems which it suggests to the expert analyst, give it a most deserved preference, and make it almost an indispensable instrument for all who would extend our physico-mathematical sciences.

In the employment of the geometry of curve lines, especially in the doctrine of centripetal forces, it is usual to consider the ordinates, not as insisting on a rectilineal abscissa, but as diverging from a centre. This is also the usual way of conceiving all spirals and evolutrixes of curves which include space: in short, all RADIAL curves. The process for finding their evolute, or their radius of curvature, is somewhat different from that hitherto exhibited; but it is more simple. Thus, let GPM (fig. 10.) be the elliptical path of a planet, of which S is the focus. We require PC, the radius of curvature in the point P. Let Pp be a very small arch. Draw the radii SP, Sp, the tangents PT, pt; and draw ST perpendicular to PT, cutting pt in t; and Po perpendicular to Sp. Let the arch GP be $=z$, the radius SP $=y$, and the perpendicular ST $=p$. Then, it is plain, that Pp, op, Tt, are ultimately proportional to $\dot{z}$, $\dot{y}$, $\dot{p}$. The triangles PCp, and Tpt or TPt are also ultimately similar; as also the triangles PST and poP. Therefore, ultimately,

$$Tt : Pp = PT : PC$$

also $$Pp : po = PS : PT$$

therefore $Tt : po = PS : PC$, or, $\dot{p} : \dot{y} = y : r$, and

$r = \dfrac{y\,\dot{y}}{\dot{p}}$; an expression of the radius of curvature, extremely simple, and of easy application.

The logarithmic or equiangular spiral PQR (fig. 6.) affords an easy example of the use of this formula. The angle SPT, which the ordinate makes with the curve, is everywhere the same. Therefore let a be our tabular radius, and b the sine of the angle SPT. We have

$\mathrm{ST} = \dfrac{b\,y}{a}$; and therefore PC $\left(=\dfrac{y\,\dot{y}}{\dot{p}}\right) = \dfrac{a\,y\,\dot{y}}{b\,\dot{y}} = \dfrac{a\,y}{b}$.

This is to SP or y in the constant ratio of a to b, or of SP to ST : that is, ST : SP = SP : PC, the triangles SPT and PCS are similar, the angles at P and C equal, and C is a point of an equiangular spiral pyr round the centre S.

It is not meant that the construction pointed out by this theory of involution, expressed in its most general and simple form, is always the best for finding the centre of the equicurve circle. Our knowledge of, or attention to, many other properties of the curve under consideration, besides those which simply mark its relation to an absciss and ordinate, must frequently give us better constructions. But evolution is the natural genesis of a line of varying curvature. Moreover, in the most important employment of mathematical knowledge, namely, mechanical philosophy, it is well known, that the most certain and comprehensive method of solving all intricate problems is by reference of all forces and motions to three co-ordinates perpendicular to each other. Thus, without any intentional search, we have already in our hands the very fluxionary quantities employed in this doctrine; and the expression which it gives of the radius of curvature requires only a change of terms to make it a mechanical theorem.

Thus have we considered the two chief questions of evolution and involution. We have done it with as close attention to geometry as possible, that the reader's mind may become familiar with the *ipsa corpora* while acquiring the elementary knowledge, which is to be employed more expeditiously afterwards by the help of the symbolical analysis. Without such ideas in the mind, the occupation is oftentimes as much divested of thought as that of an expert accountant engaged in complex calculations; the attention is wholly turned to the rules of his art.

It now remains to consider a little the nature of this curvature of which so much has been said, and about which so many obscure opinions have been entertained. We mentioned, in an early part of this article, the unwarranted use of the terms of infinite and infinitesimal magnitude as applicable to curvature, and shewed its impropriety by the inconsistences into which it leads mathematicians. Nothing threw so much light on this subject as Mr Huyghens's Geometry of Evolution; and we should have expected that all disputes would have been ended by it. But this has not been the case; and even the most eminent geometers and metaphysicians, such as the Bernoullis and Leibnitz, have given explanations of orders of curvature that can have no existence, and explanations of that coalescence which obtains between a curve line and its equicurve circle, which are not warranted by just principles.

These errors (for such we presume to think them) arose from the method employed by the geometers of last century for obtaining a knowledge of the magnitude and variation of curvature. The scrupulous geometers of antiquity despaired of ever being able to compare a curve with a right line. The moderns, although taught by Des Cartes to define the nature of a curve by its equation, allowed that this only enabled them to exhibit a series of points through which it passed, and to draw the polygon which connects these points, but gave no information concerning the continuous *incurvated* arches, of which the sides of the polygon are the chords. They could not generally draw a tangent to any point, or from any point; but they could draw a chord through any two points. Des Cartes was the first who could draw a tangent. He contrived it so, that the equation which expresses the intersections of the curve with a circle described round a given centre should have two equal roots. This indicates the coalescence of two intersections of the common chord of the circle and the curve. Therefore a perpendicular to the radius so determined must touch the curve in the point of their union. This was undoubtedly a great

Involution. great discovery, and worthy of his genius. It naturally led the way to a much greater discovery. A circle may cut a curve in more points than two: It may cut a conic section in four points; all expressed by one equation, having four roots or solutions. What if three of these roots should be equal? This not only indicates a closer union than a mere contact, but also gives indication of the flexure of the intervening arch. For, before the union, the intersections were in the arch both of the curve and of the circle; and therefore the distinction between the union of two and of three intersections must be of the same kind with that between a straight line and an arch of *this* circle. The flexure of a circle being the same in every part, it becomes a proper index; and therefore the circle, which is determined by the coalescence of three intersections, was taken as the measure of the curvature in that point of the curve, and was called the CIRCLE OF CURVATURE, the EQUICURVE CIRCLE. There is a certain progress to this coalescence which must be noticed. Let ABD (fig. 4.) be a common parabola, EBF a line touching it in B, and BO a line perpendicular to EBF. Taking some point O in the other side of the axis for a centre, a circle may be described which cuts the curve in four points *a*, *b*, *c*, and *d*. By enlarging the radius, it is plain that the points *a* and *b* must separate, as also the points *c* and *d*. Thus, the points *b* and *c* approach each other, and at last coalesce in a point of contact B, with the parabola, and with its tangent. In the mean time, *a* and *d* have retired to A and D. If we now bring the centre O nearer to B, the new circle will fall wholly within the last circle ABD; and therefore both A and D will again approach to each other, and to B, which still continues a point of contact. It is plain that A will approach faster to B than D will do. At length, the centre being in *o*, the point A coalesces with B, and we obtain a circle ϵ B δ, touching the curve in B, and cutting it in δ: Consequently the arch B ϵ δ is wholly within, and B φ δ is wholly without the parabola; and the circle both touches and cuts the parabola in B. Here is certainly a closer union, at least on the side of *a*. But perhaps a farther diminution of the circle may bring it closer on the side of D. Join B δ. Let a smaller circle be described, touching the parabola in B, and cutting it in φ. Draw φ *c* parallel to δ B. It may be demonstrated that the new circle cuts the parabola in *c*. Now the arch between *c* and φ being without the parabola, the arch B C must be within it; and therefore this circle is within the parabola on both sides of B, and is more incurvated than the parabola. We have seen, that a circle greater than ϵ B δ is without the parabola on both sides of B; and therefore is less incurvated than the parabola. Therefore the individual circle ϵ B δ is neither more nor less curve than the parabola in the point B. Therefore the circle indicated by the coalescence of three intersections is properly named the equicurve circle; and, since we measure all curvatures by that of a circle, it is *properly* the circle of curvature, and its radius is the radius of curvature.

Had B been the vertex of the axis, every intersection on one side of B would have been similar to an intersection on the other, and there would always have been two pairs of roots that are equal; and therefore when three intersections coalesce, a fourth also coalesces, and the contact is said to be still closer.

What has now been shewn with respect to a conic section is true of every curve. When two intersections coalesce, there is a common tangent; when three coalesce, there is an equal curvature, and no other circle can pass between this circle and the curve. There cannot be a coalescence of four intersections, except when the diameter is perpendicular to the ordinates, and those are bisected by the diameter.

Mr Leibnitz, who valued himself for metaphysical refinement, and never fails to claim superiority in this particular, notices the important distinction between a simple contact and this closer union in a very well written dissertation, published in the *Acta Eruditorum*, July 1686. He calls the contact of equal curvatures an OSCULATION, and the circle of equal curvature the OSCULATING CIRCLE, and delivers several very judicious remarks with the tone of a master and instructor. He also speaks of different degrees or orders of osculation, each of which is infinitely closer than the other, as a thing not remarked by geometers. But Sir Isaac Newton had done all this before. The first twelve propositions of the *Principia* had been read to the Royal Society several years before, and were in the Registers. The *Principia* had received the imprimatur of the Society in July 1686; but was almost printed before that time. In the Scholium to the 11th Lemma, is contained the whole doctrine of contact and osculation; and in the lemma and its corollaries, is crowded a body of doctrine, which has afforded themes for volumes. The author glances with an eagle's eye over the whole prospect, and points out the prominent parts with the most compressed brevity; but with sufficient precision for marking out the more important objects, and particularly the different orders of curvature. This lemma and its corollaries are continually employed in the twelve propositions already mentioned. In 1671 he had written the first draught of his method of fluxions, where this doctrine is systematically treated; and Mr Collins had a copy of it ever since 1676. It is well known that Leibnitz, when in London, had the free perusal of the Society's records, and information at all times by his correspondence with the secretary Oldenburgh and Mr Collins. His conduct respecting the theorems concerning the elliptical motion of the planets, and the resistance of fluids, leave little room to doubt of his having availed himself in like manner of his opportunity of information on this subject. He gives a much better account of the Newtonian doctrine on this subject than in those other instances, it being more suited to his refining and paradoxical disposition.

In this and another dissertation, he considers more particularly the nature of evolution, and of that osculation which obtains between the evolutrix and the circle described by the evolved radius. He says, that it is equivalent to two simple contacts, each of which is equivalent to two intersections. An osculation produced in the evolution of a curve is therefore equivalent to four intersections. And he advises, with an air of authority, the mathematicians to attend to these remarks, as leading them into the recesses of science. He is mistaken, however; and the listening to him would prevent us from forming a just notion of osculation, and from conceiving with distinctness the singular fact of a circle both touching and cutting a curve in the same point. James Bernoulli lost his friendship, because he

Involution.

presumed to say that the presence of four intersections in an osculation is not warranted by the equation expressing those intersections.

Mr Leibnitz was misled by the way in which he had considered the osculation in the evolution of curves. It merits attention. From any point within the space ADFOA (fig. 1.), two perpendiculars may be drawn to the evolutrix *A b d f*; and therefore two circles may be described round that point, each touching the curve. Each contact is the union of two intersections. Therefore, as the centre approaches the evolute, the contacts approach each other, and they unite when the centre reaches the evolute. Therefore the osculation of evolution is equivalent to four intersections.

But when two such circles are described round a point *s*, so as that both may touch the evolutrix *A a f*, the point *s* is in the intersection of one evolved radius with the *prolongation* of another. The contact at the extremity *b* of the prolonged radius *b* B is an exterior contact, and the arch of the circle crosses the evolutrix, from without inwards, in some point more remote from A. The contact at the extremity *e* of the radius *é* E is an interior contact; and if *e s* be greater than the straight line EA, the arch of this circle crosses the curve, from within outwards, in some point nearer to A. Thus each contact is accompanied by an intersection on the side next the other contact, sometimes beyond it, and sometimes between the contacts. As the contacts approach, the intersections also approach, still retaining their characters as intersections, as the contacts still continue contacts. Also the circle next to A crosses from without inwards, and that next to *f* crosses from within outwards. They retain this character to the last; and when the contacts coalesce, the two circles coalesce over their whole circumference, still, however, crossing the curve in the same direction as before; that is, without the curve on the side of A, and within it on the side of *f*. The contacts unite as contacts, and the intersections as intersections. Thus it is that the osculating circle both touches and intersects the curve in the same point.

At *f* the osculation is indeed closer than anywhere else. The variation of curvature is less there than anywhere else, because the radius changes more slowly. It is this circumstance that determines the closeness of contact. If a circle osculates a curve, it has the same curvature. If this curvature does not change in the vicinity of the contact, the curve and circle must coincide; and the deviation of the circle (the curvature of which is everywhere the same) from the curve must proceed entirely from the variation of its curvature. This, therefore, is the important circumstance, and is indeed the characteristic of the figure as a curve line; and its other properties, by which the position of its different parts are determined, may be ascertained by means of the *variation* of its curvature, as well as by its relation to co-ordinates. Of this we have a remarkable instance at this very time. The orbit of the newly discovered planet has been ascertained with tolerable precision by means of observations made on its motions for three years. In this time it had not described the 20th part of its orbit; yet the figure of this orbit, the position of its transverse axis, the place and time of its perihelion, were all determined within 100dth part of the truth by the *observed variation* of its curvature. It therefore merits our attention in the close of this article. We know of no author who has treated the subject in so instructive a manner as Mr M'Laurin has done, by exhibiting the theorem which constitutes Newton's 11th lemma in a form which points this out even to the eye (see *M'Laurin's Fluxions*, Chap. xi. § 363, &c.). We earnestly recommend this work to the young geometer, as containing a fund of instruction and agreeable exercise to the mathematical genius, and as greatly superior in perspicuity and in ideas which can be treasured up and recollected, when required, to the greatest part of the elaborate performances of the eminent analysts of later times. By expressing every thing geometrically, the author furnishes us with a sort of picture, which the imagination readily reviews, and which exhibits in a train what mere symbols only give us a momentary glimpse of.

"As, of all right lines which can be drawn through a given point in the arch of a curve, that alone is the tangent which touches the arch so closely that no right line can pass between them; so, of all circles which touch a curve in a given point, that circle alone has the same curvature which touches it so closely that no circle can pass between them. It cannot coincide with the arch of the curve; and therefore the above condition is sufficient for making it equicurve. As the curve separates from the tangent by its flexure or curvature, it separates from the equicurve circle by its *change* of curvature; and as its curvature is greater or less according as it separates more or less from its tangent, so the variation of its curvature is greater or less according as it separates more or less from its equicurve circle. There can be but one equicurve circle at one point of a curve, otherwise any other circle described between them through that point will pass between the curve and the equicurve circle.

"When two curves touch each other in such a manner that no circle can pass between them, they must have the same curvature; because the arch which touches one of them so closely that no circle can pass between them, must touch the other in like manner. But circles may touch the curve in this manner, and yet there may be indefinite degrees of more or less intimate contact between the curve and its equicurve circle." This is shewn by the ingenious author in a series of propositions, of which a very short abridgment must suffice in this place.

Let any curve EMH (fig. 11.), and a circle ERB, touch a right line ET on the same side at E. Let any right line TK, parallel to the chord EB of the circle, meet the tangent in T, the curve in M, and a curve BKF (which passes through B) in K. Then, if $MT \times TK$ be everywhere equal to TE^2, the curvature of EMH in the point E is the same as that of the circle ERB; and the contact of EM and ER is so much the closer the smaller the angle is which is contained at B between the curve BKF and the equicurve circle BQE.

Let TK meet the circle in R and Q. Then, because $RT \times TQ = TE^2$, it must be $RT \times TQ = MT \times TK$; and $RT : MT = TK : TQ$. The line BKF may have any form. It may cross the circle BQR in B, as in the figure. It may touch it, or touch EB, &c. Let us first consider what situations of the point M correspond with the position of K, in that part of the curve BKF which lies without the circle BRE.

Let

Involution. Let TK move toward EB, always keeping parallel to it, till it coincide with it, or even paſs it. Then, while the point K deſcribes KB, it is evident that ſince TK is greater than TQ, TM muſt be leſs than TR, and the point M muſt always be found between T and R. The arch ME of the curve muſt be nearer to the tangent than the arch RE of the circle. If any circle be now deſcribed touching TE in E, and cutting off from EB a ſmaller chord than EB, it is clear that the whole of this ſegment muſt be within the ſegment BRE; therefore this ſmaller circle does not paſs between ERB and the curve EMH. But ſince we ſee that the curve lies without the circle, in the vicinity of E, perhaps a greater circle than ERB may paſs between it and the curve. A greater circle, touching at E, muſt cut off a chord greater than EB. Let E r b be ſuch a circle, cutting EB in b, and TQ in q. T q is neceſſarily greater than TQ. For ſince b is beyond B, and the arch BKF lies in the angle QB b, the circle E r q muſt croſs the curve FKB in ſome point; ſuppoſe F. Then while K is found in the arch FB, the point q muſt be beyond K, or T q muſt be greater than TK. Now $Tr \times Tq = TE^2, = TM \times TQ$. Therefore $TM : Tr = Tq : TQ$. Therefore T q being greater than TQ, T r muſt be leſs than TM, and the point r muſt lie without the curve, and the arch E r does not paſs between EMH and the circle ERB. In like manner, on the other ſide of EB, it will appear, that when the curve BK′F falls within the circle which touches EMH in E, and cuts off the chord EB, the arch of the curve correſponding to the arch BK′F′, lying within the circle, alſo lies within the circle. For T′K′ being leſs than TQ′, TM′ is greater than TR′, and the curve is within the circle. And, by ſimilar reaſoning, it is evident that a circle cutting off a greater chord falls without both the circle ER′B and the curve, and that a circle leſs than ER′B muſt neceſſarily leave ſome part of the curve BK′F′ without it; and therefore TK′ will be greater than T q', and the correſponding point r' muſt be without the curve. All circles therefore touching TE in E fall without both ER and EM, or within them both, according as they cut off from EB a chord greater or leſs than EB, and no circle can paſs between them when the rectangle $MT \times TK$ is always equal to ET^2, and the focus of the point K paſſes through B; that is, ERB is the equicurve circle at E.

This corroborates the ſeveral remarks that we have made on the circumſtance of a circle touching and cutting a curve in the ſame point. No other circle can be made to paſs between it and the curve, and it therefore has the ſame curvature. This may therefore be taken as a ſufficient indication of the equicurve circle; the character peculiarly aſſured to it by the nature of evolution. It muſt be noted, however, that the curve is ſuppoſed to have its concavity in the vicinity of the contact turned all the ſame way. For if the contact be in a point of contrary fluxure, even a ſtraight line will both touch and cut it in that point.

The reader cannot but remark, that MK is always the chord of a circle touching TE in E, and paſſing through M.

Let E m be another curve, touching TE in E, ſuch, that the conjugate curve k B, which always gives $Tm \times Tk = TE^2$, alſo paſſes through B. Then, by what has now been demonſtrated, the two curves EM and E m have the ſame equicurve circle ERB, and conſequently the ſame curvature in E. Then, becauſe the rectangles $RT \times TQ$, $MT \times TK$, and $mT \times Tk$, are equal, we have $Tm : TM = TK : Tk$. Therefore if the arch B k paſs between BK and BQ, the curve E m muſt paſs between the curve EM and the circle ER. E m muſt therefore have a cloſer contact with ER than EM has with it; and the ſmaller the angle QBK is which is contained between the curve and its equicurve circle, the cloſer is the contact of the curve EM and its equicurve circle ER. Thus the length of the chord EB determines the *magnitude* or degree of curvature at E, when compared with another; and the angle contained between the equicurve circle and the conjugate curve BKF determines the cloſeneſs of the contact of the curve with its equicurve circle (the angle TEB being ſuppoſed the ſame in both).

It appears, from the proceſs of demonſtration, that the curve EMH falls without or within the equicurve circle according as its conjugate curve BKF does. Alſo, when BKF cuts BQR, HME alſo cuts it. But if FQB is on the ſame ſide of QB on both ſides of the interſection B, the curve HME is alſo on the ſame ſide of it on both ſides of the contact E. It is alſo very clear, that the contact or approach to coaleſcence between the curve and its circle of curvature, is ſo much the cloſer as the conjugate curve BKF comes nearer to the adjoining arch of this circle. It muſt be the cloſeſt of all when KB touches QB, and it muſt be the leaſt ſo when KB touches EB, or has EB for an aſſymptote. The ſpace QBK is a ſort of magnified picture of the ſpace MER; and we have a ſenſible proportion of TQ to TK as the repreſentation of the proportion of TM to TR, quantities which are frequently evaneſcent and inſenſible. When QBK is a finite angle, that is, when the tangents of BQ and BK do not coincide, the angle QBK can be meaſured. But no rectilineal angle can be contained as an unit in the curvilineal angle MER. They are incommenſurable, or incomparable. Let the curve KB touch the circle QB without cutting it. This angle is equally incomparable with the former QBK; yet it has a counterpart in MER. This muſt be incomparable with the former in the ſame manner; for there is the ſame proportion between the individuals of both pairs. Thus it appears plainly, that there are curvilineal angles incomparable with each other. Yet are they magnitudes of one kind; becauſe the ſmalleſt rectilineal angle muſt certainly contain them both; and one of them contains the other. But, further, there may be indefinite degrees of this coaleſcence or cloſeneſs of contact between a curve and a circle. The firſt degree is when the ſame right line touches both. This is a *ſimple contact*, and may obtain between any curve and any circle. The next is when EMH and ERB have the ſame curvature, and when the conjugate curve FKB interſects the circle QB in any aſſignable angle. This is an *oſculation*. The third degree of contact, and ſecond of oſculation, is when the curve KB touches the circle QB, but not ſo as to oſculate. The fourth degree of contact, and third of oſculation, is when KB and QB have the ſame curvature or oſculate in the firſt degree of oſculation. This gradation of more and more intimate contact, or (more properly ſpeaking) of approximation to coaleſcence, may be continued without end, "*neque novit natura limites*,"

the

Involution. the contact of EM and ER being always two degrees closer than that of BK and BQ. Moreover, in each of those classes of contact there may be indefinite degrees. Thus, when EM and ER have the same curvature, the angle QBK admits of indefinite varieties, each of which ascertains a different closeness of contact at E. Also, though the angle QBK should be the same, the contact at E will be so much the closer the greater the chord EB is.

For TR : TM = TK : TQ

Therefore RM : TR = KQ : KT

Or RM : KQ = TR : TK ; = TR × TQ : TK × TQ, = TE^2 : TK × TQ.

Therefore, when TE is given, RM (which is then the measure of the angle of contact) is proportional to KQ directly, and to the rectangle TK × TQ inversely; and when KQ is given, RM is less in proportion as KT × TQ is greater. In the very neighbourhood of E and B, it is plain that KT × TQ is very nearly equal to EB^2, and therefore ultimately RM : KQ = ET^2 : EB^2.

It will greatly assist our conception of this delicate subject, if we view the origin of these degrees of contact as they are generated by the evolution of lines. A thread evolving from a polygon EDCBA (fig. 13.) describes with its extremity *a* a line *e d b c a*, consisting of successive arches of circles united in simple contacts. If it evolve from any continuous curve CBA, after having evolved from the lines ED, BC, the arch *c b* will be united with the circular arch *d c* by osculation of the first degree. If any other curve FC touch this evolute in a simple contact, and if the two curves FCBA and DCBA are both evolved, they will touch each other in a simple osculation in that point where they have the same radius. If FC touches DC in a simple osculation, the evolved curves will touch in an osculation of the second degree; and, in general, the osculation of the two generated curves is a degree closer than that of their evolutes; and in each state of one of the osculations, there is an indefinite variety of the other, according to the length of its radius of curvature. All this is very clear; and shews, that these degrees of contact do not indicate degrees of curvature, one of which infinitely exceeds another; for they are all finite.

The reader will do well to remark, that the magnitude, which is the subject of the above proportions, which is really of the same kind in them all, and considered as susceptible of various degrees and orders of infinitesimals, is not curvature, but lineal extension. It is RM, the subtense of the angle of contact MER. It is the linear separation from the tangent, or from the equicurve circle. It is, however, usually considered as the measure of curvature, or the proportions of this line are given as the proportions of the curvature. This is inaccurate; for curvature is unquestionably a change of direction only. As this line has generally been the interesting object in the refined study of curve lines, especially in the employment of it in the discussions of mechanical philosophy, it has attracted the whole attention, and the language is now appropriated to this consideration. What is called, by the most eminent mathematicians, variation of curvature, is, in fact, variation of the subtense of the angle of contact. But it is necessary always to distinguish them carefully.

Variation of curvature is the remaining object of our attention. Involution.

Curvature is uniform in the circle alone. When the curvature of the arch EMH (fig. 11.) decreases as we recede from E, the arch, being less deflected from its primitive direction ET than the arch ER, must separate less from the line ET, or must fall without the arch ER. The more rapidly its curvature decreases, the describing point must be left more without the circle. It must be the contrary, if its curvature had increased from E toward M. It may change its curve equably or unequably. If equably, there must be a certain uniform rate, which would have produced the same final change of direction in a line of the same length, bending it into the uniformly incurvated arch of a circle. It is not so obvious how to estimate a rate of variation of curvature; and authors of eminence have differed in this estimation. Sir Isaac Newton, who was much interested in this discussion, in his studies on universal gravitation, seems to have adopted a measure which best suited his own views; and has been followed by the greater number. He gives a very clear conception of what he means, by stating what he thinks a case of an invariable rate of variation. This is the equiangular spiral, all the arches of which, comprehended in equal angles from the centre, are perfectly similar, although continually varying in curvature. He calls this a curve EQUABLY VARIABLE, and makes its rate of variation (estimated in that sense in which it is uniform) the measure of the rate of variation in all other curves. Let us see in what respect its variation of curvature is constant. It may be described by the evolution of the same spiral in another position (see fig. 6.), and the ratio between the radius of the evolute and that of the evolutrix is always the same; or (which amounts to the same thing) the arch of the evolutrix bears to the evolved arch of the evolute a constant ratio. The curvature of the spiral changes more rapidly in the same proportion as the ratio of the evolved arch to the arch of the evolutrix generated by it is greater, or as it cuts the radii in a more acute angle. These arches may be infinitesimal; therefore the fraction $\frac{\text{fluxion of evolute}}{\text{fluxion of evolutrix}}$ expresses the rate of the variation of curvature in this spiral, Now let *a b c d* (fig. 13.) be any other curve, and ABCD its evolute; let *p* be the centre of curvature at the point B of the evolute, and B *o* the evolved arch; draw the radii *p* B, *p o*, B *m*, *o n*; join *p m*, and draw B *q* perpendicular to *p m*. It is evident that *m n* and B *o* have the same ratio with B *m* and B *p*; and that these two small arches may be conceived as being portions of the same equiangular spiral (perhaps in another position), of which *q* is the centre; and that *p* is in the curve of another of the same. For *q p* : *q* B = *q* B : *q* M, = *p* B : B *m*; therefore the ratio of these infinitesimal arches *m n* and B *o* will express the rate of variation in any curve. This is evidently equivalent to saying, that the variation of curvature is proportional to the fluxion of the radius of curvature directly, and the fluxion of the curve inversely. For *m n* and B *o* are ultimately as those fluxions, and $\frac{B o}{m n}$ is equivalent to $\frac{\dot{r}}{\dot{z}}$, where *z* is the arch of the spiral, and *r* the evolved radius of the other. Accordingly,

ingly, this is the enunciation of the INDEX OF VARIATION given by Newton (See Newton's Fluxions, Prob. VI. § 3.). Therefore, what Newton calls a uniform variation of curvature, is not an increase or diminution by equal arithmetical differences, but by equal proportions of the curvature in every point. The variation of curvature in similar points of similar arches is supposed to be the same.

It is evident that this ratio is the same with that of radius to the tangent of the angle $p\,m$ B, or of 1 to its tabular tangent. The tangent therefore of this angle corresponding to any point of a curve is the measure of the variation of curvature in that point. Now it may be shewn (and it will appear by and bye), that the fluxion of TK in fig. 11. or the ultimate value of KQ, is always $\frac{2}{3}$ds of the fluxion of the radius of curvature. Therefore the tangent of the angle QBK is always $\frac{2}{3}$ds of that of $p\,m$ B; and therefore the angle QBK, which we have seen to be an index of the closeness of contact, is also the index of the variation of curvature (See *M'Laurin*, § 386.).

Sir Isaac Newton has given specimens of the use of this measure in a variety of geometrical curves, by means of a general expression of $\frac{\dot{r}}{\dot{z}}$. Thus, in the curve ABC (fig. 8.), let AB be $= z$, AD $= x$, DB $= y$, BN $= r$, and BE $= p$; we have $\frac{\text{N}n}{\text{B}b} = \frac{\dot{r}}{\dot{z}}$. Now DB : BE $= y : p, =$ D d : B $b, = \dot{x} : \dot{z}$. Therefore $\dot{z} = \frac{p\dot{x}}{y}$, and $\frac{\dot{r}}{\dot{z}} = \frac{y\dot{r}}{p\dot{x}}$. Now, in every curve which we can express by an equation, we can obtain all these quantities p, y, $\dot{r}$, and $\dot{z}$, and can therefore obtain the measure of the variation of curvature. It also deserves particular notice, that this investigation of $\frac{\dot{r}}{\dot{z}}$ is equivalent with finding the centre and radius of curvature of the evolute, by which the curve under consideration is generated; or with finding the centre q (fig. 13.) of an equiangular spiral, which will touch our curve in m, its evolute in B, and the evolute of the evolute in p, if put into different positions when necessary. This leads to very curious speculations, for which, however, we have no room. It has been said, for instance, that the curvature at the intersection of a cycloid with its base is infinitely greater than that of any circle. If the evolution of the cycloid begin from this point, the curvature of its evolutrix will be infinitely greater still upon the same principles; and we shall have one infinitely greater than this by evolving it. Yet all these infinities, multiplied to infinity, are contained in the central point of every equiangular spiral! In like manner, there are evolutrixes which coincide with a straight line, and others of infinitely greater rectitude, and still they are curves. Can this have any meaning? And can it be reconciled with the legitimate reasoning from the same principles, that all these curvatures and angles of contact are producible by evolution; and that they may be, and certainly are every day described, by bodies moving in free space, and acted on by accelerating forces directed to different bodies?

The parabola (conical) is the most simple of all the lines of unequably varying curvature, and becomes a very good standard of comparison. In the parabola ABC (fig. 8.) let the parameter be $2\,a$. The equation is then $2\,a\,x = y^2$; DE $= a$; p, or BE $= \sqrt{a^2 + y^2}$ DQ $= a + 2\,x$ (by what was formerly demonstrated). Moreover, DB : BE = DQ : BN; and BN $= \frac{pa + 2px}{a}$, $= r$. These equations give $2\,a\,\dot{x} = 2\,y\,\dot{y}, = 2\,p\,\dot{p}$; and $\frac{a\dot{p} + 2\,x\,\dot{p} + 2\,p\dot{x}}{a} = \dot{r}$. Now making $\dot{x} = 1$, and reducing the equations, we obtain $\dot{y} = \frac{a}{y}$; $\dot{p} = \frac{y\dot{y}}{p} = \frac{a}{p}$; and $\dot{r} = \frac{a\dot{p} + 2\,x\,\dot{p} + 2\,p}{a}$.

With these values of $\dot{y}, \dot{p}, \dot{r}$, we obtain a numeric value of $\frac{y\,\dot{r}}{p}$ most readily. Thus, in order to obtain the index of variation of curvature in the point where the ordinate at the focus cuts the parabola, make $a = 1$. Then $2\,x = y^2$; $x = \frac{1}{2}$, $y\ (= \sqrt{2\,x}) = 1$; $\dot{y}\left(= \frac{a}{y}\right) = 1$; $p\ (= \sqrt{a^2 + y^2}) = \sqrt{2}$; $\dot{p}\left(= \frac{a}{p}\right) = \sqrt{\tfrac{1}{2}}$, and $\dot{r}\left(= \frac{a\dot{p} + 2\,x\,\dot{p} + 2\,p}{a}\right) = \sqrt{2} \times 3$. Therefore $\frac{y\,\dot{r}}{p} = 3$, = the index of variation in the point B when D is the focus of the parabola; that is to say, the fluxion of the radius of curvature is three times the fluxion of the curve.

The index of variation, where the ordinate is equal to the parameter, is had by making $x = 2$. This gives $y = 2$; $\dot{y} = \frac{1}{2}$; $p = \sqrt{5}$; $\dot{p} = \sqrt{\tfrac{1}{5}}$, and $\dot{r} = 3\sqrt{5}$. Wherefore $\frac{y\,\dot{r}}{p} = 6$, which is the index of variation. Moreover, since p and $\dot{r}$ are in a constant ratio, it appears that the index of variation of curvature in the parabola is proportional to the ordinate y. It is always $= 6\,\frac{\text{ordinate}}{\text{parameter}}$; and thus, with very little trouble, we can describe the evolute of its evolute, *i. e.* of the semicubical parabola.

In like manner, it may be shewn, that in all the conic sections $\frac{\dot{r}}{\dot{z}}$ is always proportional to the rectangle of the ordinate DB and the subnormal DE, or to DB × DE. In the parabola, whose equation is $2\,a\,x = y^2$, we have $\frac{\dot{r}}{\dot{z}} = \frac{3\,y}{a}$. In an ellipse, whose equation is $2\,a\,x - b\,x^2 = y^2$, we have $\frac{\dot{r}}{\dot{z}} = \frac{3 - 3\,b}{a} \times$ DB × DE, and in the hyperbola, whose equation is $2\,a\,x + b\,x^2$, $\frac{\dot{r}}{\dot{z}}$ is $= \frac{2 + 3\,b}{a} \times$ DB × DE. This ratio, in all the three sections, is always as the tangent of the angle contained between the diameter and the normal at the point of contact. By this we may compare them with a parabola. In the cycloid at the point E

Involution, ‖ Joan.

(fig. 5.) $\frac{\dot{y}}{\dot{z}}$ is = tan. ∠ EKM, &c. &c.

All these things may be traced in the observations made on fig. 11. and 12. When the angle BET is a right angle, the angle KBQ indicates it directly, its tangent being always $= \frac{2r}{3z}$. It is easy also to see, that when the curve EMH is a parabola, the line BKF is a straight line parallel to ET. It is also plain, that by the same steps that we proved that no circle can pass between this parabola and its equicurve circle ERB, so no other parabola can pass between them. Indeed the same reasoning will prove that no curve of the same kind can pass between any curve and its osculating circle. In many cases, it is more easy to reason from the curvature of a curve, by comparing it with an equicurve parabola than with an equicurve circle; particularly in treating of the curvilineal motions of bodies in free space, actuated by deflecting forces.

If EMH be an ellipse or hyperbola, BKF is another ellipse or Hyperbola (*M'Laurin*, § 373.)

We have thus endeavoured to introduce our readers into this curious branch of speculative geometry. An introduction is all that can be expected from a work of this kind. We have enlarged on particular points, in proportion as we thought that the notions entertained on the subject were inadequate, or even vague and indistinct; and we hope that some may be incited to acquire clearer conceptions by going to the fountain head. We conclude, by recommending to the young geometer the perusal of the Fluxions of Sir Isaac Newton, after he has read M'Laurin's Chapter with care. He will probably be surprised and delighted with seeing the whole compressed by a master's hand into such narrow compass with such beautiful perspicuity.

JOAN D'ARC, the maid of Orleans, has been variously characterised; but all now agree, that she was worthy of a better fate than the horrid death she was doomed to die. (See JOAN *d'Arc*, *Encycl.*). But did she actually die that death? An ingenious writer in the *Monthly Magazine* has proved, we think, that she did not.

The bishop of Beauvais (says he) is accused by all parties of treachery and trick in the conduct of the trial: it was his known propensity to gain his ends by stratagem, craft, manœuvre, fraud, dexterity. He seeks out, and brings forward, such testimony only as relates to ecclesiastical offences, and then hands over the decision to the secular judges, whose clemency he invokes. Joan says to him publicly, "You * *promised* to restore me to the church, and you deliver me to my enemies." The intention of the bishop, then, must have been, that the secular judges, for want of evidence, should see no offence against the state; as the clerical judges, notwithstanding the evidence, had declined to see any against the church. A fatal sentence was, however, pronounced; and the fulfilment of it entrusted to the ecclesiastical authorities. Immediately after the *auto da fé*, one of the executioners ran to two friars, and said, "that he had never been so shocked at any execution, and that the English had built up † a scaffolding of plaster (*un echafaud de platre*) so lofty, that he could not approach the culprit, which must have caused her sufferings to be long and horrid." She was, therefore, by some *unusual* contrivance, kept out of the reach and observation even of the executioners.

Joan, ‖ John.

Some time after, when public commiseration had succeeded to a vindictive bigotry, a woman appeared at Metz‡, who declared herself to be Joan of Arc. She was everywhere welcomed with zeal. At Orleans, especially, where Joan was well known, she was received with the honours due to the liberatress of the town. She was acknowledged by both her brothers, Jean and Pierre d'Arc. On their testimony she was married by a gentleman of the house of Amboise, in 1436. At their solicitation her sentence was annulled in 1456. The Parisians, indeed, long remained incredulous: they must else have punished those ecclesiastics, whose humanity, perhaps, conspired with the bishop of Beauvais to withdraw her from real execution down a central chimney of brick and mortar; or, as the executioner called it, a scaffolding of plaster. The king, for the woman seems to have shunned no confrontation, is stated to have received her with these words: "*Pucelle, m'amie, soyez la tres bien revenue, au nom de Dieu.*" She is then said to have communicated to him, kneeling, the artifice practised. Can this woman be an impostor? Our author thinks not, and appeals to Voltaire, who, in his prose works, seems willing to allow that she was not, as is too commonly imagined, one of those half-insane enthusiasts, employed as tools to work upon the vulgar; whom the one party endeavoured to cry up as a prophetess, and the other to cry down as a witch; but that she was a real heroine, superior to vulgar prejudice, and no less remarkable by force of mind than for a courage and strength unusual in her sex. This opinion is certainly countenanced by her behaviour in adversity, and during her trial, which was firm without insolence, and exalted without affectation.

JOHN, BAYOUK OF ST, a little creek which furnishes a very easy communication from New-Orleans to West-Florida. It is navigable for vessels drawing about 4 feet water 6 miles up from the lake Ponchartrain, where there is a landing place, at which vessels load and unload: this is about 2 miles from the town. The entrance of the Bayouk of St John is defended by a battery of 5 or 6 cannon. There are some plantations on the Bayouk, and on the road from thence to New-Orleans.—*Morse.*

JOHN DE FRONTIERA, ST, is the chief town of the province of Cuyo in Peru.—*ib.*

JOHN'S COLLEGE, ST, in Maryland, is situated in the city of Annapolis, was instituted in 1784, to have 24 trustees, with power to keep up the succession by supplying vacancies, and to receive an annual income of £9,000. It has a permanent fund of £1,750 a year, out of the monies arising from marriage licenses, fines and forfeitures on the Western Shore. This college, with Washington college at Chestertown, constitute one university, named "The University of Maryland." The convocation of the University of Maryland, who are to frame the laws, preserve uniformity of manners and literature in the colleges, confer the higher degrees, determine appeals, &c.—*ib.*

JOHN'S ISLAND, in South-Carolina, lies S. W. of Charleston harbour, divided from James's Island by Stono river, which forms a convenient and safe harbour. —*ib.*

John's. JOHN'S, ST, one of the chief towns of Newfoundland island, situated on the east coast, 6 miles north-west of Cape Spear, and 18 south-east of Cape St Francis. N. lat. 47° 32', W. long. 52° 21'. It lies on the bay of the same name. Its harbour is one of the best in the island, and has from 10 to 17 fathoms water up to King's wharf, which is a little to the north-west of the Old Fort, at the bottom of the town, and is a mile from the mouth of the harbour. A mile further is the mouth of Castor river, in which distance there is from 14 to 4 fathoms of water. On the south side of this river is King's wharf, an hospital, and a watering place. Near these are the hills called the High Lands of St John's. N. lat. 47° 32', W. long. 52° 29'.—*ib.*

JOHN'S, ST, a bay and island on the west coast of Newfoundland island, in the gulf of St Lawrence, at the south-west end of the straits of Bellisle.—*ib.*

JOHN'S RIVER, ST, in East-Florida rises in or near a large swamp in the heart of East-Florida, and pursues a northern course, in a broad navigable stream, which in several places spreads into broad bays or lakes; of which Lake George is the chief. Vessels that draw 9 or 10 feet water, may navigate safely through the west channel into St John's river as far as Lake George. The bar at the mouth is liable to shift. It is 10½ leagues north of St Augustine.—*ib.*

JOHN'S RIVER, *Little St*, in West Florida, falls into Apalache Bay, about 10 miles eastward of Apalache river. It is said to be the clearest and purest of any in America, is about 200 yards broad, and about 15 or 20 feet deep at the town of Talahasochete. The swamp called Ouaquaphenogaw is said to be its source, which is 100 miles by land from Talahasochete, and, following its windings, from the sea 200 miles. The Indians and traders say it has no branches, or tributaries, which fall into it; but that it is fed by great springs which break out through the banks.—*ib.*

JOHN'S, ST, is the largest river in the British province of New-Brunswick. From its mouth on the north side of the bay of Fundy, to its main source is computed to be 350 miles. The tide flows 80 or 90 miles up this river. It is navigable for sloops of 50 tons 60 miles, and for boats 200. Its general course from its source is E. S. E. It furnishes the greatest plenty of salmon, bass, and sturgeon; and is the common route to Quebec. About a mile above the city of St John's is the only entrance into this river. It is about 80 or 100 yards wide, and about 400 yards in length; called the falls of the river. It being narrow, and a ridge of rocks running across the bottom of the channel, on which are not above 17 feet of water, it is not sufficiently spacious to discharge the fresh waters of the river above. The common tides flowing here about 20 feet, the waters of the river, at low water, are about 12 feet higher than the waters of the sea; at high water, the waters of the sea are about five feet higher than those of the river; so that in every tide there are two falls, one outwards and one inwards. The only time of passing with safety is at the time when the waters of the river are level with the waters of the sea, which is twice in a tide, and continues not more than 20 minutes each time. At other times it is either impassable or extremely dangerous; resembling the passage of Hell Gate near New-York. The banks of this river, enriched by the annual freshets, are excellent land. About 30 miles from its mouth commences a fine level country of rich intervale and meadow lands, well cloathed with timber and wood, such as pine, beech, elm, maple, and walnut. It has many tributary streams, which fall into it on each side, among which are the Oromocto river, by which the Indians have a communication with Passamaquoddy, the Nashwach and Madamkiswick, on which are rich intervales that produce all kinds of grain in the highest perfection. This noble river, in its numerous and extensive branches, waters and enriches a large tract of excellent country, a great part of which is settled and under improvement. The up-lands, in general, are covered with a fine growth of timber, such as pine and spruce, hemlock and hardwood, principally beech, birch, maple, and some ash. The pines on this river are the largest to be met with in British America, and afford a considerable supply of masts, some from 20 to 30 inches in diameter, for the British navy.—*ib.* John's.

JOHN'S, ST, one of the Virgin Islands, about 12 leagues east of Porto Rico. It is about 5 miles long and 1 broad; and 2 leagues south of St Thomas. It is the best watered of all the Virgin Isles; and its harbour, called Crawl Bay, is reckoned better than that of St Thomas, and passes for the best to the leeward of Antigua. There is, however, little good land in the island and its exportations are trifling.—*ib*

JOHN'S, ST, an island in the gulf of St Lawrence, near the northern coast of Nova-Scotia, to which government it is annexed. It is 117 miles in length from N. E. to S. W. The medium breadth is 20 miles; but between Richmond Bay on the north, and Halifax Bay on the south, it is not above 3 miles broad. The other bays on the north side are London Harbour, Grand Rastied, and St Peters; those on the south side, Egmont, Halifax, and Hillsborough. On the east side, Three River Harbour, and Murry Harbour. It has several fine rivers, a rich soil, and is pleasantly situated. Its capital is Charlotte-Town, the residence of the lieutenant-governor, who is the chief officer on the island. The number of inhabitants are estimated at about 5,000. Upon the reduction of Cape Breton in 1745, the inhabitants quietly submitted to the British arms. While the French possessed this island, they improved it to so much advantage, as that it was called the granary of Canada, which it furnished with great plenty of corn, as well as beef and pork. When taken it had 10,000 head of black cattle upon it, and several of the farmers raised 12,000 bushels of corn annually. Its rivers abound with salmon, trout, and eels, and the surrounding sea affords plenty of sturgeon, plaice, and most kinds of shell-fish. The island is divided into 3 counties, viz. King's, Queen's, and Prince's counties; which are subdivided into 14 parishes, consisting of 27 townships, which in all make 1,363,400 acres, the contents of the island. The chief towns, besides the capital, are Georgetown, Prince's-Town; besides which are Hillsborough-Town, Pownal-Town, Maryborough-Town, &c. It lies between 45° 46', and 47° 10 N. lat. and between 44° 22', and 46° 32 W. long.—*ib.*

JOHN'S, ST, the north-westernmost town in Sussex county, Delaware, is situated at the head of the middle branch of Nanticoke river, about 27 miles N. E. of Vienna in Maryland, and 22 S. by W. of Dover.—*ib.*

JOHN'S, ST, a town and fort in Lower Canada, situated

ated on the west bank of Sorel river, at the north end of lake Champlain, a few miles southward of Chamblee, 28 miles southward of Montreal. It has been established as the sole port of entry and clearance for all goods imported from the interior of the United States into Canada, by an ordinance published by the executive council of Lower Canada, the 7th of July, 1796. It is 115 miles northward of Ticonderoga, and was taken by General Montgomery in Nov. 1775. N. lat. 45° 9′, W. long. 72° 18′.—*ib.*

JOHN, ST, a lake in Lower-Canada, which receives rivers from every direction, and sends its waters through Saguenai river into the St Lawrence, at Tadousac. It is about 25 miles each way.—*ib.*

JOHN'S BERKLEY, ST, a parish of S. Carolina, in Charleston district, containing 5,922 inhabitants; of whom 692 are whites, and 5,170 are slaves.—*ib.*

JOHN'S, ST, a small island in the West-Indies belonging to Denmark, north of St Croix, and south of Tortola, to which last it is very near. It is noted only for its fine harbour, which is said to be sufficient to contain in safety the whole British navy. It has a number of salt ponds, which, however, are no evidence of its fertility.—*ib.*

JOHN'S COLLETON, ST, a parish of S. Carolina, in Charleston district, containing 5,312 inhabitants; of whom 585 are whites, and 4,705 slaves.—*ib.*

JOHN'S, ST, the capital of the island of Antigua in the West-Indies. It is a regularly built town, with a harbour of the same name, situated on the west shore, and on the north-east side of Loblollo Bay. The entrance of the harbour is defended by Fort James. this town is the residence of the governor general of the leeward Charaibe Islands, and where the assembly is held, and the port where the greatest trade is carried on. It was so flourishing as to receive a loss by a storm, to the value of £400,000 sterling. N. lat. 17° 4′, W. long. 62° 4′.—*ib.*

JOHN, ST, or *Juan de Porto Rico*, the capital of the island of Porto Rico, in the West-Indies.—*ib.*

JOHNSBURY, ST, a township in Caledonia county, in Vermont, bounded S. W. by Danville, and has 143 inhabitants.—*ib.*

JOHNSON FORT, in S. Carolina, lies on the N. E. side of James's Island, and south of the city of Charleston. It stands at the entrance of the harbour, and by which no vessel can pass unless the master or mate make oath that no malignant distemper is on board. It is guarded by 10 men.—*ib.*

JOHNSTON FORT, or *Johnson Fort*, in N. Carolina, stands on the western bank of Cape Fear river, opposite to the island on the sea-coast whose southern point is Cape Fear.—*ib.*

JOHNSONSBOROUGH, a post-town of New-Jersey, 10 miles from Sussex court-house.—*ib.*

JOHNSON'S LANDING-PLACE, is on O-yongwongyeh Creek, about 4 miles eastward of Fort Niagara.—*ib.*

JOHNSON, a county of N. Carolina, in Newbern district, bounded S. E. by Glasgow, N. by Franklin and Wayne counties, and S. by Sampson. It contains 5634 inhabitants, of whom 1329 are slaves.—*ib.*

JOHNSTOWN, a post-town and the capital of Montgomery county, New-York, situated on the N. bank of Mohawk river, 24 miles W. of Schenectady. The compact part of the town is a little back from the river, and contains about 70 houses, a Presbyterian and an Episcopal church, a court-house and gaol. In the township 593 of the inhabitants are electors. Caghnawaga is a parish or district of Johnstown 26 miles above Schenectady on the river. Settlements have been made here for about 80 years. Here stand the dwelling house, barn, and out-houses (all of stone) formerly occupied by Sir William Johnson. This settlement was mostly destroyed by the British in the year 1780, who were joined by a party of Indians and others, under the command of Sir William Johnson. In this action it is asserted, that Sir William evinced a want of feeling which would have disgraced a savage. The people destroyed in this expedition were his old neighbours, with whom he had formerly lived in the habits of friendship. His estate was among them; and the inhabitants had always considered him as their friend. These unfortunate people, after seeing their houses and property consumed, were hurried, such as could walk, into cruel captivity; those who could not, fell victims to the tomahawk and scalping knife.—*ib.*

JOHNSTON, a township in Providence county, Rhode-Island, westerly of the town of Providence, having 1320 inhabitants.—*ib.*

JOHNSTON, a township in Franklin county, in Vermont; it contains 93 inhabitants.—*ib.*

JONAS'S SOUND, the most northern inlet on the western coast of Sir Thomas Smith's Bay, lying near the arctic circle, in latitude 76°.—*ib.*

JONES (Sir William), who was styled by Johnson the most enlightened of men, was the son of William Jones, Esq; one of the last of those genuine mathematicians, admirers, and contemporaries of Newton, who cultivated and improved the sciences in the last century. Our author was born on the 28th of September 1746, and received his education at Harrow school, under the care of Dr Robert Sumner, whom he has celebrated in an eulogium which will out-last brass or marble. We are told that he was a class fellow with Dr Parr, and at a very early age displayed talents which gave his tutor the most promising expectations, and which have since been amply justified. From Harrow he was sent to University college, Oxford, where the rapidity and elegance of his literary acquisitions excited general admiration; while a temper, ardently generous, and morals perfectly irreproachable, procured him testimonies of the most valuable esteem. The grateful affection which he always cherished for that venerable seat of learning, did as much honour to his sensibility, as Oxford herself has received by enrolling him among the number of her sons.

In the twenty-third year of his age he travelled through France, and resided some time at Nice, where he employed himself very differently from most other young men who make what is called the tour of Europe. *Man*, and the influence of various forms of *government*, were the principal objects of his investigation; and in applying the result of his inquiries to the state of his own country, he mingled the solicitudes of the Patriot with the honest partialities of an Englishman.

Mr Jones's first literary work was a translation into French of a Persian manuscript, entitled "*Histoire de Nadir Shah, connu sous le nom de Thahmas Kuli Khan, Empereur de Perse*," in two vols. 4to; the history of which performance we shall give in his own words;

Jones.

words: "A great northern monarch, who visited this country a few years ago, under the name of the Prince of Travendal, brought with him an eastern manuscript, containing the life of Nadir Shah, the late sovereign of Persia, which he was desirous of having translated in England. The secretary of state, with whom the Danish minister had conversed upon the subject, sent the volume to me, requesting me to give a literal translation of it in the French language; but I wholly declined the task, alledging for my excuse the length of the book, the dryness of the subject, the difficulty of the style, and chiefly my want both of leisure and ability to enter upon an undertaking so fruitless and so laborious. I mentioned, however, a gentleman, with whom I had not then the pleasure of being acquainted, but who had distinguished himself by a translation of a Persian history, and was far abler than myself to satisfy the king of Denmark's expectations. The learned writer, who had other works upon his hands, excused himself on the account of his many engagements; and the application to me was renewed. It was hinted, that my compliance would be of no small advantage to me at my entrance into life; that it would procure me some mark of distinction which might be pleasing to me; and, above all, that it would be a reflection upon this country, if the king should be obliged to carry the manuscript into France. Incited by these motives, and principally by the last of them, unwilling to be thought churlish or morose, and eager for the bubble reputation, I undertook the work, and sent a specimen of it to his Danish Majesty; who returned his approbation of the style and method, but desired that the whole translation might be perfectly literal, and the oriental images accurately preserved. The task would have been far easier to me, had I been directed to finish it in Latin; for the acquisition of a French style was infinitely more tedious; and it was necessary to have every chapter corrected by a native of France, before it could be offered to the discerning eye of the public, since in every language there are certain peculiarities of idiom, and nice shades of meaning, which a foreigner can never learn to perfection. But the work, how arduous and unpleasing soever, was completed in a year, not without repeated hints from the secretary's office that it was expected with great impatience by the Court of Denmark." The translation of the History of Nadir Shah was published in the summer of the year 1770, at the expence of the translator; and forty copies upon large paper were sent to Copenhagen; one of them bound with uncommon elegance for the king himself, and the others as presents to his courtiers.*

* Preface to the History of Nadir Shah, 1770.

What marks of distinction our author received, or what fruits he reaped for his labour, he has not thought proper to disclose; but if any dependence is to be placed on common fame, the reward bestowed upon him for this laborious task consisted only in the thanks of his Danish Majesty, and the honour of being enrolled in the Royal Society of Copenhagen. That distinction was indeed accompanied with a letter, recommending the learned translator to the patronage of his own sovereign; but, in the interim, his friend Lord Dartmouth, who was to have delivered it, had resigned his office of secretary of state, and the letter, we are told, was never presented.

There is reason to think, that this early and severe disappointment made a deep impression on his mind, and induced him to renounce the muses for a time, and to apply himself with assiduity to the study of jurisprudence. This we think apparent, from the style in which he writes of his return from the continent, and of the death of his beloved preceptor Dr Sumner.

"When I left Nice, (says he) where I had resided near seven months, and after traversing almost all France, returned to England, I most ardently desired to pass several years more in the study of polite literature; as then, I thought, I might enter into public life, to which my ambition had always prompted me, more mature and prepared: but with this fruit of my leisure, either fortune, or rather Providence, the disposer of all human events, would not indulge my sloth; for on a sudden, I was obliged to quit that very literature to which, from my childhood, I had applied myself; and he who had been the encourager and assistant of my studies, who had instructed, taught, formed me such as I was, or if I am any thing at all, ROBERT SUMNER, within a year after my return, was snatched away by an untimely death (A)."

In

(A) As a specimen of our author's latinity, we subjoin the epitaph on Dr Sumner, which is affixed to the wall of the south transept of Harrow church.

H. S. E.

Morte correptus prid. Id. Sept. A. D.
1771, Æt. 41.

Jones.

In 1771 Mr Jones published *Dissertation sur la Literature Orientale*, 8vo, and this was followed by *Lettre à Monsieur A** Du P***, dans laquelle est compris l' Examen de sa Traduction des Livres attribues à Zoroastre*, 8vo. The dissertation offered a favourable specimen of the author's abilities as a linguist and as a critic; and the letter contained a spirited vindication of the university of Oxford, from the very scurrilous reproaches, in which its incompetency in Oriental literature was asserted by the illiberal translator of the supposed works of the Persian philosopher.

In the same year he gave to the public, "A Grammar of the Persian language," 4to, and at the same time proposed to republish Meninski's Dictionary, with improvements from *De Labrosse's Gazophylacium Linguæ Persarum*, and to add in their proper place an Appendix subjoined to Gehanaguire's Persic Dictionary. The Grammar has been found extremely useful, and has been reprinted several times; but the design of the Dictionary, though an object of even national importance, for want of due encouragement was obliged to be laid aside.

In 1772 he published "Poems; consisting chiefly of Translations from the Asiatic Languages. To which are added two Essays; 1. On the Poetry of the Eastern Nations. 2. On the Arts commonly called Imitative," 8vo, which in 1777 he republished with the addition of some Latin Poems, every way worthy of their author. On the 18th June 1773, he took the degree of Master of Arts, and the same year published "The History of the Life of Nadir Shah, King of Persia. Extracted from an Eastern Manuscript, which was translated into French by order of his Majesty the King of Denmark. With an Introduction, containing, 1. A Description of Asia according to the Oriental Geographers. 2. A short History of Persia from the earliest Times to the present Century: And an Appendix, consisting of an Essay on Asiatic Poetry, and the History of the Persian Language. To which are added Pieces relative to the French Translation," 8vo. Our author having at this period determined to study the law as a profession, and to relinquish every other pursuit, our readers will not be displeased with the following extract, relating to this resolution, which concludes the preface to the history now under consideration:

"To conclude; if any essential mistakes be detected in this whole performance, the reader will excuse them, when he reflects upon the great variety of dark and intricate points which are discussed in it; and if the obscurity of the subject be not a sufficient plea for the errors which may be discovered in the work, let it be considered, to use the words of Pope in the preface to his juvenile poems, that there are very few things in this collection which were not written under the age of five-and-twenty: most of them indeed were composed in the intervals of my leisure in the South of France, before I had applied myself to a study of a very different nature, which it is now my resolution to make the sole object of my life. Whatever then be the fate of this production, I shall never be tempted to vindicate any part of it which may be thought exceptionable; but shall gladly resign my own opinions, for the sake of embracing others, which may seem more probable; being persuaded, that nothing is more laudable than the love of truth, nothing more odious than the obstinacy of persisting in error. Nor shall I easily be induced, when I have disburdened myself of two other pieces which are now in the press, to begin any other work of the literary kind; but shall confine myself wholly to that branch of knowledge in which it is my chief ambition to excel. It is a painful consideration, that the profession of literature, by far the most laborious of any, leads to no real benefit or true glory whatsoever. Poetry, science, letters, when they are not made the sole business of life, may become its ornaments in prosperity, and its most pleasing consolation in a change of fortune; but if a man addicts himself entirely to learning, and hopes by that, either to raise a family, or to acquire, what so many wish for, and so few ever attain, an honourable retirement in his declining age, he will find, when it is too late, that he has mistaken his path; that other labours, other studies, are necessary; and that unless he can assert his own independence in active life, it will avail him little to be favoured by the learned, esteemed by the eminent, or recommended even by kings. It is true, on the other hand, that no external advantages can make amends for the loss of virtue and integrity, which alone give a perfect comfort to him who possesses them. Let a man, therefore, who wishes to enjoy, what no fortune or honour can bestow, the blessing of self-approbation, aspire to the glory given to Pericles by a celebrated historian, of being acquainted with all useful knowledge, of expressing what he knows with copiousness and freedom, of loving his friends and country, and of disdaining the mean pursuits of lucre and interest: this is the only career on which an honest man ought to enter, or from which he can hope to gain any solid happiness."

The next year he published *Poeseos Asiaticæ Commentariorum Libri Sex, cum Appendice: subjicitur Limon, seu Miscellaneorum Liber*, 8vo; and pursuing his purpose of applying to the study of the law, we hear no more of him from the press (except the new edition of his Poems), until the year 1779. In this interval he was called to the bar, and attended Westminster hall and the Oxford circuit, where he obtained but little business. He was however appointed a commissioner of bankrupts by Lord Bathurst, who is supposed to have intended to exert his interest to procure his nomination to the bench in the East Indies.

He published in this year, "The speeches of Iseus, in causes concerning the law of succession to property at Athens; with a preparatory discourse, notes critical and historical, and a Commentary, 4to." In this valuable work, the talents of the scholar, the critic, and the lawyer, combine to elucidate a very important part of jurisprudence; for, "though deep researches into the legal antiquities of *Greece* and *Rome* (as he observes in his Commentary) are of greater use to scholars and contemplative persons, than to lawyers and men of business; though Bracton and Lyttleton, Coke and Rolle, are the proper objects of our study; yet the ablest advocates, and wisest judges, have frequently embellished their arguments with learned allusions to ancient cases; and such allusions, it must be allowed, are often useful, always ornamental; and,

Jones.

and, when they are introduced without pedantry, never fail to pleaſe." The work was dedicated in a ſtyle of reſpectful gratitude to his patron Lord Bathurſt.

In the year 1780, we find our author a candidate to repreſent in parliament the univerſity of Oxford. He had for ſome time reſided but little in the univerſity, and therefore laboured under ſome diſadvantages; but he did not meanly court the ſupport of any man. In a paper, which was circulated on that occaſion, his friends, who were numerous, declare, that they have "neither openly ſolicited, nor intend openly to ſolicit, votes for Mr Jones within the Univerſity itſelf, becauſe he will never become the inſtrument of diſturbing the calm ſeat of the Muſes, by conſenting to any ſuch ſolicitation for himſelf or for any man whatever. His own applications have been, are, and will be, confined to thoſe only who have profeſſed a regard for him, *and who have no votes themſelves:* the Maſters of Arts in a great univerſity, whoſe prerogative is cool reaſon and impartial judgment, muſt never be placed on a level with the voters of a borough, or the freeholders of a county. Even in proceeding thus far, he does not ſet the example, but follows it; and his friends would never have printed any paper, if they had not thought themſelves juſtified by the conduct of others.

"For the firſt and the laſt time, they beg leave to ſuggeſt, that no exertions muſt be ſpared by theſe who, either perſonally or by reputation, approve the character of Mr Jones; into which, both literary and political, as well as moral, his friends deſire and demand the ſtricteſt ſcrutiny. For his univerſity he began early to provoke, and poſſibly to incur, the diſpleaſure of great and powerful men: For his univerſity he entered the liſts with a foul-mouthed and arrogant Frenchman, who had attacked Oxford in three large volumes of miſrepreſentation and ſcurrility: For his univerſity he reſigned, for a whole year, his favourite ſtudies and purſuits, to ſave Oxford the diſcredit of not having one of her ſons ready to tranſlate a tedious Perſian manuſcript. To Oxford, in ſhort, he is known to be attached by the ſtrongeſt poſſible ties; and only regrets the neceſſity of abſenting himſelf from the place in which of all others he moſt delights, until the event of the preſent competition ſhall either convince him that he has toiled in vain as a man of letters, or ſhall confer on him the greateſt reward to which he can aſpire. The unavoidable diſadvantage of being ſo late propoſed, and the reſpectable ſupport with which he is now honoured, will ſecure him in all events from the leaſt diſgrace." The application was unſucceſsful, chiefly becauſe his own college had fixed upon another candidate, from a perſuaſion that the immediate appointment of Mr Jones to a ſeat, then vacant on the bench of judges in India, was morally certain.

The riots of that year gave occaſion to another publication of our author, entitled, "An Inquiry into the legal Mode of ſuppreſſing Riots; with a conſtitutional Plan of future Defence," 8vo; and in 1781 he publiſhed "An Eſſay on the Law of Bailments," 8vo, a very maſterly treatiſe, which did great honour to his legal abilities. In this laſt work he inculcates the neceſſity of deeply exploring the grounds of the common law; and ſpeaking of Blackſtone, (he ſays) "his commentaries are the moſt correct and beautiful outline that ever was exhibited of any human ſcience; but they alone will no more form a lawyer, than a general map of the world, how accurately and elegantly ſoever it may be delineated, will make a geographer."

Jones.

In this year he likewiſe recalled his muſe in an Ode on the nuptials of Lord Viſcount Althorpe, who had been his pupil, to Miſs Lavinia Bingham. This beautiful little poem is preſerved in the European Magazine for January 1785, and we think in other periodical publications.

From many circumſtances which might be collected together, it would appear that our author at this juncture did not coincide in opinion with thoſe who had the direction of government, nor did he approve the meaſures at that period adopted.—With theſe ſentiments he ſeems to have been ſelected as a proper perſon to be introduced as a member of the Conſtitutional Society. Could he have foreſeen the degeneracy of ſuch aſſociations, there is reaſon to believe that he would have declined what he condeſcended to accept as an honour; for though an ardent friend to liberty, he was an enemy to theoretical innovation, and declares, in a letter to the ſecretary, that by the term conſtitution, he underſtands "the great ſyſtem of public, in contradiction to private and criminal law, which compriſes all thoſe articles which Blackſtone arranges, in his firſt volume, under the rights of perſons, and of which he gives a perſpicuous analyſis. Whatever then relates to the rights of perſons, either abſolute rights, as the enjoyment of liberty, ſecurity, and property, or relative, that is, in the public relations of magiſtrates and people, makes a part of that majeſtic whole, which we properly call the conſtitution. This conſtitutional or public law is partly unwritten, and grounded upon immemorial uſage, and partly written or enacted by the legiſlative power; but the unwritten, or common law, contains the true ſpirit of our conſtitution: the written has often moſt unjuſtifiably altered the form of it; the common law is the collected wiſdom of many centuries, having been uſed and approved by ſucceſſive generations; but the ſtatutes frequently contain the whims of a few leading men, and ſometimes of the mere individuals employed to draw them."

In 1782 he publiſhed "The Mahomedan Law of Succeſſion to the Property of Inteſtates, in Arabic, with a verbal Tranſlation and explanatory Notes." 4to.

At length the poſt of one of the judges in the Eaſt Indies, which had been kept vacant five years, was determined upon being filled up; and our author, on the 4th March 1783, was appointed to that ſtation, and on the 20th received the honour of knighthood. On the 8th of April he married Miſs Shipley, eldeſt daughter of the Biſhop of St Aſaph, and almoſt immediately embarked for the Indies. He had previouſly publiſhed "The Moallakat; or, Seven Arabian Poems, which were ſuſpended on the Temple at Mecca, with a Tranſlation and Arguments." 4to. To this it was intended to add a preliminary diſcourſe and notes.—The former to compriſe obſervations on the antiquity of the Arabian language and letters; on the dialects and characters of Himyar and Koraiſh, with accounts of ſome Himyarick poets; on the manners of the Arabs in the age immediately preceding that of Mahomed; on the temple at Mecca, and the Moallakat, or pieces of poetry suspended on its walls or gate; lastly, on the lives of the Seven Poets, with a critical history of their works, and the various copies or editions of them preserved in Europe, Asia, and Africa. The latter to contain authorities and reasons for the translation of controverted passages; to elucidate all the obscure couplets, and exhibit or propose amendments of the text; to direct the reader's attention to particular beauties, or point out remarkable defects; and to throw light on the images, figures, and allusions of the Arabian poets, by citations either from writers of their own country, or from such of our European travellers as best illustrate the ideas and customs of Eastern nations. This discourse and the notes have not yet appeared. At his departure for the eastern world, he left, in manuscript, with his brother-in-law the Dean of St Asaph, a little tract, entitled "The Principles of Government, in a Dialogue between a Scholar and a Peasant." This celebrated dialogue being afterwards published by the Dean, and widely circulated by the society for constitutional information, the Dean was prosecuted for publishing a libel, and, if our memory deceives us not, was found guilty.

Sir William Jones now dropt for ever all concern in party politics, and applied himself to pursuits more worthy of his talents. During his voyage to India, he conceived the idea of the Asiatic Society, of which an account has been given under the title SOCIETIES (*Encycl.*), and of whose researches five volumes, replete with much curious information, are now before the public. But ardently as his mind was attached to general literature and science, he was by no means inattentive to the professional duties of his high station. He had indeed, to use his own expression, an "undissembled fondness for the study of jurisprudence *;" and in the character of a judge, displayed the profound knowledge and irreproachable integrity, which, before his promotion, pervaded his reasonings as a lawyer, and governed his conduct as a man. Unfortunately the intense ardour of application, which produced his frequent contributions to the stock of human knowledge, added to the unfavourable influence of the climate, greatly impaired his health. On this account, after a residence of about fifteen years in India, he made preparations for returning to England; but death interposed; and this illustrious ornament of science and virtue was taken from the world on the 27th of April 1794, in the 48th year of his age. "It is to the shame of scepticism (as one of his biographers well observes), to the encouragement of hope, and to the honour of genius, that this great man was a sincere believer in the doctrines of Christianity, and that he was found in his closet in the attitude of addressing his prayer to God." We shall give his character as it was drawn by Sir John Shore, Baronet, (now Lord Teignmouth) in a discourse delivered at a meeting of the Asiatic Society, held on the 22d of May 1794.

* *Law of Bailments.*

"His capacity for the acquisition of languages has never been excelled. In Greek and Roman literature, his early proficiency was the subject of admiration and applause; and knowledge of whatever nature, once obtained by him, was ever afterwards progressive. The more elegant dialects of modern Europe, the French, the Spanish, and Italian, he spoke and wrote with the greatest fluency and precision; and the German and Portuguese were familiar to him. At an early period of life his application to Oriental literature commenced; he studied the Hebrew with ease and success; and many of the most learned Asiatics have the candour to avow, that his knowledge of Arabic and Persian was as accurate and extensive as their own; he was also conversant in the Turkish idiom, and the Chinese had even attracted his notice so far as to induce him to learn the radical characters of that language, with a view perhaps to farther improvements. It was to be expected, after his arrival in India, that he would eagerly embrace the opportunity of making himself master of the Sanscrit; and the most enlightened professors of the doctrines of Brahma confess with pride, delight, and surprise, that his knowledge of their sacred dialect was most critically correct and profound. The Pandits, who were in the habit of attending him, could not, after his death, suppress their tears for his loss, nor find terms to express their admiration at the wonderful progress he had made in their sciences.

"Before the expiration of his twenty-second year, he had completed his Commentaries on the Poetry of the Asiatics, although a considerable time afterwards elapsed before their publication; and this work, if no other monument of his labours existed, would at once furnish proofs of his consummate skill in the Oriental dialects, of his proficiency in those of Rome and Greece, of taste and erudition far beyond his years, and of talents and application without example.

"But the judgment of Sir William Jones was too discerning to consider language in any other light than as the key of science, and he would have despised the reputation of a mere linguist. Knowledge and truth were the objects of all his studies, and his ambition was to be useful to mankind; with these views he extended his researches to all languages, nations, and times.

"Such were the motives that induced him to propose to the government of India, what he justly denominated a work of national utility and importance, the compilation of a copious Digest of Hindu and Mahomedan Law, from Sanscrit and Arabic originals, with an offer of his services to superintend the compilation, and with a promise to translate it. He had foreseen, previous to his departure from Europe, that without the aid of such a work, the wise and benevolent intentions of the legislature of Great Britain, in leaving to a certain extent the natives of these provinces in possession of their own laws, could not be completely fulfilled; and his experience, after a short residence in India, confirmed what his sagacity had anticipated, that without principles to refer to, in a language familiar to the judges of the courts, adjudications amongst the natives must too often be subject to an uncertain and erroneous exposition, or wilful misinterpretation of their laws.

"To the superintendance of this work, which was immediately undertaken at his suggestion, he assiduously devoted those hours which he could spare from his professional duties. After tracing the plan of the Digest, he prescribed its arrangement and mode of execution, and selected from the most learned Hindus and Mahomedans fit persons for the task of compiling it: flattered by his attention, and encouraged by his applause, the

the Pandits prosecuted their labours with cheerful zeal to a satisfactory conclusion. The Molavees have also nearly finished their portion of the work; but we must ever regret, that the promised translation, as well as the meditated preliminary dissertation, have been frustrated by that decree, which so often intercepts the performance of human purposes.

"During the course of this compilation, and as auxiliary to it, he was led to study the works of Menu, reputed by the Hindus to be the oldest and holiest of legislators; and finding them to comprise a system of religious and civil duties, and of law in all its branches, so comprehensive and minutely exact, that it might be considered as the institutes of Hindu Law, he presented a translation of them to the government of Bengal. During the same perind, deeming no labour excessive or superfluous that tended in any respect to promote the welfare or happiness of mankind, he gave the public an English version of the Arabic Text of the Sirajiyah or Mahomedan Law of Inheritance, with a Commentary. He had already (as has been observed) published in England a translation of a tract on the same subject by another Mahomedan lawyer, containing, as his own words express, 'a lively and elegant Epitome of the Law of Inheritance of Zaid.'

"To these learned and important works, so far out of the road of amusement, nothing could have engaged his application but that desire which he ever professed, of rendering his knowledge useful to his nation, and beneficial to the inhabitants of these provinces.

"I should scarcely (continues Lord Teignmouth) think it of importance to mention, that he did not disdain the office of editor of a Sanscrit and Persian work, if it did not afford me an opportunity of adding, that the latter was published at his own expence, and was sold for the benefit of insolvent debtors. A similar application was made of the produce of Sirajiyah."

But nothing exhibits the large grasp of Sir William Jones's mind in so striking a point of view as a paper in his own hand writing, which came into Lord Teignmouth's possession after his death. It was intitled DESIDERATA, and proposed for investigation the following subjects relating to the eastern world.

India.—1. The ancient geography of India, &c. from the Puranas. 2. A botanical description of Indian plants, from the Cosha, &c. 3. A grammar of the Sanscrit language, from Panini, &c. 4. A dictionary of the Sanscrit language, from the 32 original vocabularies and Nirusti. 5. On the ancient music of the Indians. 6. On the medical substances of India, and the Indian art of medicine. 7. On the philosophy of the ancient Indians. 8. A translation of the Veda. 9. On ancient Indian geometry, astronomy, and algebra. 10. A translation of the Puranas. 11. A translation of the Mahabbara and Ramayan. 12. On the Indian theatre, &c. &c. 13. On the Indian constellations, with their mythology, from the Puranas. 14. The history of India before the Mahomedan conquest, from the Sanscrit Cashmir Histories.

Arabia.—15. The history of Arabia before Mahomed. 16. A translation of the Hamasa. 17. A translation of Hariri. 18. A translation of the Facahatul Khulafa. Of the Cafiah.

Persia.—19. The history of Persia, from authorities in Sanscrit, Arabic, Greek, Turkish, Persian ancient and modern, Firdausi's Khrosrau nama. 20. The five poems of Nizami, translated in prose. 21. A dictionary of pure Persian Je-changire.

China.—22. A translation of Shi-cing. 23. The text of Can-fu-tsu, verbally translated.

Tartary.—24. A history of the Tartar nations, chiefly of the Moguls and Othmans, from the Turkish and Persian.

"We are not authorised (says his Lordship) to conclude, that he had himself formed a determination to complete the works which his genius and knowledge had thus sketched; the task seems to require a period beyond the probable duration of any human life; but we, who had the happiness to know Sir William Jones; who were witnesses of his indefatigable perseverance in the pursuit of knowledge, and of his ardour to accomplish whatever he deemed important; who saw the extent of his intellectual powers, his wonderful attainments in literature and science, and the facility with which all his compositions were made—cannot doubt, if it had pleased Providence to protract the date of his existence, that he would have ably executed much of what he had so extensively planned."

We have already enumerated attainments and works which, from their diversity and extent, seem far beyond the capacity of the most enlarged minds; but the catalogue may yet be augmented. To a proficiency in the languages of Greece, Rome, and Asia, he added the knowledge of the philosophy of those countries, and of every thing curious and valuable that had been taught in them. The doctrines of the Academy, the Lyceum, or the Portico, were not more familiar to him than the tenets of the Vedas, the mysticism of the Sufis, or the religion of the ancient Persians; and whilst, with a kindred genius, he perused with rapture the heroic, lyric, or moral compositions of the most renowned poets of Greece, Rome, and Asia, he could turn with equal delight and knowledge to the sublime speculations or mathematical calculations of Barrow and Newton. With them also he professed his conviction of the truth of the Christian religion; and he justly deemed it no inconsiderable advantage, that his researches had corroborated the multiplied evidence of Revelation, by confirming the Mosaic account of the primitive world.

In his eighth anniversary discourse to the Asiatic Society, he thus expresses himself: "Theological inquiries are no part of my present subject; but I cannot refrain from adding, that the collection of tracts which we call, from their excellence, the Scriptures, contain, independently of a divine origin, more true sublimity, more exquisite beauty, purer morality, more important history, and finer strains both of poetry and eloquence, than could be collected within the same compass from all other books that were ever composed in any age, or any idiom. The two parts, of which the Scriptures consist, are connected by a chain of compositions, which bear no resemblance in form or style to any that can be produced from the stores of Grecian, Indian, Persian, or even Arabian learning; the antiquity of these compositions no man doubts, and the unstrained application of them to events long subsequent to their publication, is a solid ground of belief that they were genuine predictions; and consequently inspired."

There were, in truth, few sciences in which he had not acquired considerable proficiency; in most, his knowledge

knowledge was profound. The theory of music was familiar to him; nor had he neglected to make himself acquainted with the interesting discoveries lately made in chemistry; "and I have heard him (says Lord Teignmouth) assert, that his admiration of the structure of the human frame had induced him to attend for a season to a course of anatomical lectures, delivered by his friend the celebrated Hunter."

His last and favourite pursuit was the study of botany, which he originally began under the confinement of a severe and lingering disorder, which with most minds would have proved a disqualification from any application. It constituted the principal amusement of his leisure hours. In the arrangements of Linnæus, he discovered system, truth, and science, which never failed to captivate and engage his attention; and from the proofs which he has exhibited of his progress in botany, we may conclude that he would have extended the discoveries in that science.

It cannot be deemed useless or superfluous to inquire by what arts or method he was enabled to attain to a degree of knowledge almost universal, and apparently beyond the powers of man, during a life little exceeding 47 years.

The faculties of his mind, by nature vigorous, were improved by constant exercise; and his memory, by habitual practice, had acquired a capacity of retaining whatever had once been impressed upon it. To an unextinguished ardour for universal knowledge, he joined a perseverance in the pursuit of it which subdued all obstacles; his studies began with the dawn, and, during the intermissions of professional duties, were continued throughout the day; reflection and meditation strengthened and confirmed what industry and investigation had accumulated. It was a fixed principle with him, from which he never voluntarily deviated, not to be deterred by any difficulties that were surmountable from prosecuting to a successful termination what he had once deliberately undertaken.

But what appeared more particularly to have enabled him to employ his talents so much to his own and the public advantage, was the regular allotment of his time, and a scrupulous adherence to the distribution which he had fixed; hence all his studies were pursued without interruption or confusion. He collected information, too, from every quarter; justly concluding, that something might be learned from the illiterate, to whom he listened with the utmost candour and complacency.

Lord Teignmouth, addressing himself to the Asiatic Society, says, "Of the private and social virtues of our lamented President, our hearts are the best records. To you who knew him, it cannot be necessary for me to expatiate on the independence of his integrity, his humanity, probity, or benevolence, which every living creature participated; on the affability of his conversation and manners, or his modest, unassuming deportment: nor need I remark, that he was totally free from pedantry, as well as from arrogance and self-sufficiency, which sometimes accompany and disgrace the greatest abilities. His presence was the delight of every society, which his conversation exhilarated and improved; and the public have not only to lament the loss of his talents and abilities, but that of his example.

"To him, as the founder of our institution, and whilst he lived its firmest support, our reverence is more particularly due. Instructed, animated, and encouraged by him, genius was called forth into exertion, and modest merit was excited to distinguish itself. Anxious for the reputation of the Society, he was indefatigable in his own endeavours to promote it, whilst he cheerfully assisted those of others. In losing him, we have not only been deprived of our brightest ornament, but of the guide and patron, on whose instructions, judgment, and candour, we could implicitly rely." Though these are the sentiments, not only of Lord Teignmouth, but, we believe, of every man of letters, we trust there is still left in Bengal a sufficient love of letters and of science to carry on the plan which was formed by the genius of Sir William Jones.

JONES, a county of N. Carolina, in Newbern district, bounded N. by Craven. It contains 3141 free inhabitants, and 1681 slaves. It is well watered by Trent river, and its tributary streams. Chief town Trenton.—*Morse.*

JONESBOROUGH, a post-town, and chief town of Washington district in Tennessee, is the seat of the district and county courts. It has but few houses, having been but lately established. It is 26 miles from Greenville, 101 from Knoxville, 40 from Abingdon in Virginia, and 627 from Philadelphia.—*ib.*

Jonesborough, the chief town of Camden county in Edenton district, N. Carolina. It contains a court-house and a few dwelling-houses.—*ib.*

JONES's PLANTATION, in Lincoln county, Maine, was incorporated by the name of Harlem, in February, 1796. It is 19 miles N. E. of Hallowell, 47 from Pownalborough, and 213 N. E. by N. of Boston. It contains 262 inhabitants.—*ib.*

Jones's Ford, on Brandywine creek, is 5 or 6 miles above Chad's Ford, in Pennsylvania.—*ib.*

JONESIA, is a very handsome middling-sized ramous tree, found in gardens about Calcutta. In the Sanscrit it is called *As'óca*, and in the Bengalese *Ruffuck*; but the name Jonesia was given to it by the Asiatic Society, who consecrated it to the memory of their first president Sir William Jones. It is thus described by Dr Roxburgh, a member of that society:

"*Calyx*, two leaved, corol, one petaled, pistil bearing; base of the tube impervious; stamens long, ascending, inserted into the margin of a glandulous nectarial ring, which crowns the mouth of the tube, the uppermost two of which more distant; style declining. *Legume* turgid. *Trunk* erect, though not very straight. *Bark* dark brown, pretty smooth. *Branches* numerous, spreading in every direction, so as to form a most elegant shady head. *Leaves* alternate, abruptly feathered, sessile, generally more than a foot long; when young pendulous and coloured. *Leaflets* opposite, from four to six pair, the lowermost broad lanced, the upper lanced; smooth, shining, firm, a little waved, from four to eight inches long. *Petiole* common, round, and smooth. *Stipule* axillary, solitary; in fact a process from the base of the common petiole, as in many of the grasses and monandrists, &c. *Umbels* terminal and axillary; between the stipule and branchlet, globular, crowded, subsessile, erect. *Bracts*, a small hearted one under each division of the umbel. *Peduncle* and pedicels smooth, coloured. *Flowers* very numerous, pretty large; when they first expand they are of a beautiful orange colour, gradually changing to red, forming a variety of lovely shades;

shades; fragrant during the night. *Calyx* perianth, below two-leaved, leaflets small, nearly opposite, coloured, hearted, bracte-like, marking the termination of the pedicel, or beginning of the tube of the corol. *Corol* one-petalled, funnel form; tube slightly incurved, firm, and fleshy, tapering towards the base (club funnel-shaped) and there impervious; border four-parted; division spreading, suborbicular; margins most slightly woolly: one-third the length of the tube. *Nectary*, a stameniferous and pistiliferous ring crowns the mouth of the tube. *Stamens*, filaments generally seven; and seven must, I think, be the natural number; viz. three on each side, and one below, above a vacancy, as if the place of an eighth filament, and is occupied on its inside by the pistil; they are equal, distinct, ascending, from three to four times longer than the border of the corol. *Anthers* uniform, small, incumbent. *Pistil*, germ oblong, pediceled; pedicel inserted into the inside of the nectary, immediately below the vacant space already mentioned; style nearly as long as the stamens, declining; stigma simple. *Pericarp*, legume scimeter-formed, turgid, outside reticulated, otherwise pretty smooth; from six to ten inches long, and about two broad. *Seeds* generally from four to eight, smooth; grey, size of a large chesnut."

The Jonesia flowers at the beginning of the hot season, and its seeds ripen during the rains. The plants and seeds were originally brought to Calcutta from the interior parts of the country, where it is indigenous. *N. B.* Many of the flowers have only the rudiment of a pistil. In Plate XXX. A is a branchlet of the natural size. B, A single flower a little magnified; *a a* the calyx. C, A section of the same, exhibiting four of the stamens, 1 1 1 1 the pistil 2, and how far the tube is perforated. D, A similar section of one of the abortive flowers; 3 is the abortive pistil. E, The ripe legume opening near the base, natural size. *Note*, The space between the *b* and *c* marks the original tube of the corol. F, One of the seeds, natural size. G, The base of the common petiole, with its stipule; *a a*, the petioles of the lower pair of leaflets.

JOOTSI-SIMA, a small flat island, which is separated from Cape Nota in Japan by a channel about five leagues wide. Its circumference does not exceed two leagues; it is well wooded, of an agreeable aspect, and well inhabited. Perouse, who sailed round it, remarked from the quarter deck of his ship some considerable edifices between the houses of the inhabitants; and hard by a fort of castle, at the south-west point of the island, he distinguished some gibbets. He does not, however, affirm that those gibbets were for the execution of criminals; for, as he observes, it would be singular enough if the Japanese, whose customs are so different from ours, were in this point to resemble us so nearly. He represents the island as surrounded with dreadful breakers; at the distance of a league and a half from which, he had constantly 60 fathoms, with rocky bottom. He places the island (differently, according to the editor of his voyage, from all other geographers) in latitude 37° 51′ north, and in Long. 135° 20′ east from Paris.

JOPPA, a small town in Harford county, Maryland, 20 miles E. by N. of Baltimore, and 82 S. W. of Philadelphia.—*Morse.*

JORDAN's *River* passes through Trenton, in the District of Maine, 8 miles from Union river.—*ib.*

JORE, a village and mountain in the Cherokee country. The mountain is said to be the highest in the Cherokee country, and through which the Tennessee river forces its waters. The Indian village, called Jore, is situated in a beautiful lawn, many thousand feet higher than the adjacent country. Here is a little grove of the Casine Yapon, called by the Indians the beloved tree. They are very careful to keep this tree pruned and cultivated, and drink very strong infusion of the leaves, buds, and tender branches of this plant. It is venerated by the Creeks, and all the southern maritime nations of Indians.—*ib.*

JOSEPH, LAKE ST, in N. America, lies E. of Lake Sal, and sends its waters by Cat Lake river into Cat Lake, and afterwards forms the S. E. branch of Severn river. The lake is 55 miles long and 15 broad. Osnaburg House is on the N. E. part of the lake.—*ib.*

JOSEPH, *Ilet à Pierre*, a village on the westernmost coast of the island of St Domingo; about 3 leagues N. W. of the village of Tiburon.—*ib.*

JOSEPH's, ST, in the province of California, in Mexico, N. America. N. lat. 23° 3′.—*ib.*

JOSEPH's BAY, ST, on the coast of West-Florida, is of the figure of a horse-shoe, being about 12 miles in length, and 7 across where broadest. The bar is narrow, and immediately within it there is from 4 to 6½ fathoms soft ground. The best place to anchor, is just within the peninsula, opposite to some ruins that still remain of the village of St Joseph. The peninsula between St Joseph's and Cape Blaze is a narrow slip of land, in some places not above a quarter of a mile broad. A very good establishment might be made here for a fishery, as the settlers might make salt on the spot to cure the bass, rock, cod, grouper, red mullet, &c. which are here in abundance.—*ib.*

JOSEPH, ST, a water which runs N. W. into the S. E. part of Lake Michigan. It springs from a number of small lakes, a little to the N. W. of the Miami village. The Pawtewatamie Indians reside on this river, opposite Fort St Joseph. They can raise 200 warriors. At or near the confluence of the rivers St Mary's and St Joseph's where Fort Wayne now stands, the Indians have ceded to the United States a tract of 6 miles square.—*ib.*

JOSEPH, *Fort St*, is situated on the eastern side of the above river in N. lat. 42° 14′, W. long. 86° 10′. It is about 175 miles S. W. by W. of Detroit, to which place there is a straight road.—*ib.*

JOSEPH, ST, a port on the W. side of the island of Trinidad, near the coast of Terra Firma.—*ib.*

JOURNALS, the title of periodical publications. See *Encyclopædia*. The principal British Journals are: *The History of the Works of the Learned*, begun at London in 1699. *Censura Temporum*, in 1708. About the same time there appeared two new ones; the one under the title of *Memoirs of Literature*, containing little more than an English translation of some articles in the foreign Journals, by M. de la Roche; the other, a collection of loose tracts, intitled, *Bibliotheca Curiosa*, or a Miscellany. These, however, with some others, are now no more, but are succeeded by the *Annual Register*, which began in 1758; the *New Annual Register*, Journals, Ipswich. Ipswich, Iron.

A r, begun in 1780; the *Monthly Review*, which began in the year 1749, and gives a character of all English literary publications, with the most considerable of the foreign ones: the *Critical Review*, which began in 1756, and is nearly on the same plan: as also the *London Review*, by Dr Kenrick, from 1775 to 1780; *Maty's Review*, from Feb. 1782 to Aug. 1786; the *English Review*, begun in Jan. 1783; and the *Analytical Review*, begun in May 1788, dropt in 1798, and revived in 1799, under the title of the *New Analytical Review*: but again dropt after two or three months trial: the *British Critic*, begun in 1792, and still carried on with much spirit and ability: the *Anti-Jacobin Review and Magazine*, commenced in 1798, for the meritorious purpose of counteracting the pernicious tendency of French Principles in politics and religion: the *New London Review*, January 1799: *A Journal of Natural Philosophy, Chemistry, and the Arts*, which was begun in 1797 by Mr Nicholson, and has been conducted in such a manner, that it is one of the most valuable works of the kind to be found in any language: the *Philosophical Magazine*, begun in 1798 by Mr Tilloch, and carried on upon much the same plan, and with much the same spirit, as Nicholson's Journal.

Besides these, we have several monthly pamphlets, called *Magazines*, which, together with a chronological series of occurrences, contain letters from correspondents, communicating extraordinary discoveries in nature and art, with controversial pieces on all subjects. Of these, the principal are those called the *Gentleman's Magazine*, which began with the year 1731; the *London Magazine*, which began a few months after, and has lately been discontinued; the *Universal Magazine*, which is nearly of as old a date; the *Scotch Magazine*, which began in 1739, and is still continued; the *European Magazine*; and the *Monthly Magazine*, a miscellany of much information, which began in January 1796.

IOWA, a river of Louisianna, which runs southeastward into the Mississippi, in N. lat. 41° 5′, 61 miles above the *Iowa Rapids*, where on the E. side of the river is the *Lower Iowa Town*, which 20 years ago could furnish 300 warriors. The *Upper Iowa Town* is about 15 miles below the mouth of the river, also on the E. side of the Mississippi, and could formerly furnish 400 warriors.—*Morse*.

JOYST or Jeyst, the second month of the Bengal year.

IPSWICH, the *Agawam* of the Indians, is a post-town and port of entry on both sides of Ipswich river, in Essex county, Massachusetts, 12 miles south of Newburyport, 10 north-east of Beverly, 32 N. E. by N. of Boston, and about a mile from the sea. The township of Ipswich is divided into 5 parishes, and contains 601 houses, and 4502 inhabitants. There is an excellent stone bridge across Ipswich river, composed of two arches, with one solid pier in the bed of the river, which connects the two parts of the town, executed under the direction of the late Hon. Judge Choate. This was heretofore a place of much more consideration than at present. Its decline is attributed to a barred harbour and shoals in the river. Its natural situation is pleasant, and on all accounts excellently well calculated to be a large manufacturing town. The supreme judicial court, the courts of common pleas and sessions are held here once a year, on the 1st Tuesday of April; and from its central situation, it appears to be the most convenient place for all the courts and public offices of the county. The inhabitants are chiefly farmers, except those in the compact part of the township. A few vessels are employed in the fishery and a few trade to the West Indies. Silk and thread lace, of an elegant texture, are manufactured here by women and children, in large quantities, and sold for use and exportation in Boston, and other mercantile towns. In 1790, no less than 41,979 yards were made here, and the manufacture is rather increasing. Ipswich township was incorporated in 1634, and is 378 miles N. E. of Philadelphia. N. lat. 42° 43′, W. long. 70° 50′.—*Morse*.

Ipswich, New, a township in Hillsborough county, New-Hampshire, containing 1241 inhabitants, situated on the west side of Souheagan river, and separated from Whatohook Mountain by the north line of Massachusetts; 56 miles N. W. of Boston, and about 77 west of Portsmouth. It was incorporated in 1762, and has in it a flourishing academy.—*ib.*

IRASBURG, a township in Orleans county, in Vermont, situated on Black river, 17 miles N. of Hazen Block-house, and 12 S. of the Canada line.—*ib.*

IREDELL COUNTY, in Salisbury district, N. Carolina, is surrounded by Surry, Rowan, and Burke. The climate is agreeable and healthy; the lands beautifully variegated with hills, and the soil is rich. It contains 5435 inhabitants of whom 858 are slaves. At *Iredell* court-house is a post-office. It is 25 miles from Salisbury, and 25 from Charlotte court-house.—*ib.*

IRELAND, NEW, a long narrow island in the Pacific ocean, N. of New Britain, extending from the N. W. to the S. E. about 270 miles, and in general very narrow; between 3° and 5° S. lat. and 146° 30′, and 151° E. long. from Paris. The inhabitants are negroes. The island is covered with wood, and abounds with pigeons, parrots, and other birds. West and N. W. of New Ireland, lie Sandwich, Portland, New Hanover, and Admiralty Islands, discovered and named by Captain Carteret, in 1767. The tracks of Le Maire and Schouten in 1616, of Roggewin in 1722, and of Bouganville in 1768, pass these islands.—*ib.*

IROIS, POINTE DE, or *Irish Point*, a village on the W. end of the island of St Domingo.—*ib.*

IRON, is by much the most useful of all the metals, as has been sufficiently proved under the article Iron, *Encycl.* and under Chemistry in this *Supplement*. The word is again introduced here, because it affords us an opportunity of laying before our readers some valuable observations by Chaptal on the use of the *oxyds* of iron in dyeing cotton.

"The oxyd of iron has such an affinity for cotton thread, that if the latter be plunged in a saturated solution of iron in any acid whatever, it immediately assumes a chamoy yellow colour, more or less dark, according to the strength of the liquors. It is both a curious and easy experiment, that when cotton is made to pass through a solution of the sulphat of iron, rendered turbid by the oxyd which remains suspended in the liquor, it will be sufficient to dip the cotton in the bath to catch

Iron.

catch the last particle of the oxyd, and to restore to the liquor the transparency it has lost. The solution, then, which before had a yellowish appearance, becomes more or less green, according as it is more or less charged.

"The colour given to cotton by the oxyd of iron becomes darker, merely by exposure to the air; and this colour, soft and agreeable when taken from the bath, becomes harsh and ochry by the progressive oxydation of the metal. The colour of the oxyd of iron is very fast: it resists not only the air and water, but also alkaline leys, and soap gives it splendour without sensibly diminishing its intensity. It is on account of these properties that the oxyd of iron has been introduced into the art of dyeing, and been made a colouring principle of the utmost value.

"In order that the oxyd of iron may be conveniently applied to the cotton thread, it is necessary to begin by effecting its solution; and, in this case, acids are employed as the most useful solvents. Dyers almost everywhere make a mystery of the acid which they employ; but it is always the acetous, the sulphuric, the nitric, or the muriatic. Some of them ascribe great differences to the solution of iron by the one or the other acid; but, in general, they give the preference to the acetous. This predilection appears to be founded much less on the difference of the colours that may be communicated by the one or the other salt, than on the different degrees of corrosive power which each exercises on the stuff. That of the sulphat and muriat is so great, that if the stuff be not washed when it comes from the bath, it will certainly be burnt; whereas solutions by the acetous, or any other vegetable acid, are not attended with the like inconvenience.

"Iron appears to be at the same degree of oxydation in the different acids, since it produces the same shade of colour when precipitated; and any acid solvent may be employed indiscriminately, provided the nature of the salt, and the degree of the saturation of the acid, be sufficiently known; for the subsequent operations may be then directed according to this knowledge, and the inconveniences which attend the use of some of these salts may be prevented. This, without doubt, is a great advantage which the man of science enjoys over the mere workman, who is incapable of varying his process according to the nature and state of the salts which he employs.

"1. If the sulphat of iron, or any other martial salt, be dissolved in water, and cotton be dipped in the liquid, the cotton will assume a chamoy colour, more or less dark according as the solution is more or less charged. The affinity of the cotton to the iron is so great, that it attracts the metal, and takes it in a great measure from the acid by which it was dissolved.

"2. If the iron of a pretty strong solution be precipitated by an alkaline liquor that shews five or six degrees (by the areometer of Baumé), the result will be a greenish blue magma. The cotton macerated in this precipitate assumes at first an unequal tint of dirty green; but mere exposure to the air makes it in a little time turn yellow, and the shade is very dark.

"It is by such, or almost similar processes, that dyers communicate what is called among workmen an *okre* or *rust colour*. But these colours are attended with several inconveniences to the artist: 1. Strong shades burn or injure the cloth: 2. This colour is harsh, disagreeable to the eye, and cannot be easily united with the mild colours furnished by vegetables."

To avoid these inconveniences, our author made several attempts, which led him to the following practice: He treads the cotton cold in a solution of the sulphat of iron, marking three degrees: he wrings it carefully, and immediately plunges it in a ley of potash at two degrees, upon which he has previously poured to saturation a solution of the sulphat of alumine: the colour is then brightened, and becomes infinitely more delicate, soft, and agreeable. The sulphat no longer attacks the tissue of the stuff; and after the cotton has been left in the bath for four or five hours, it is taken out to be wrung, washed, and dried. In this manner we may obtain every shade that can be wished, by graduating the strength of the solutions. This simple process, the theory of which presents itself to the mind of every chemist, has the advantage of furnishing a colour very agreeable, exceedingly fixed, and, above all, extremely economical. He employs it with great advantage in dyeing nankeens, as it has the property of resisting leys. It becomes brown, however, by the action of astringents.

M. Chaptal made several attempts to combine this yellow with the blue of indigo, in order to obtain a durable green; but as they were all unsuccessful, he infers that there is not a sufficient affinity between the blue of indigo and the oxyds of iron. He found that these oxyds, on the other hand, combine very easily with the red of madder, and produce a bright violet or plum colour, the use of which is as extensive as beneficial in the cotton manufactory. But if we should confine ourselves to apply these two colours to cotton, without having employed a mordant capable of fixing the latter, the colour would not only remain dull and disagreeable by the impossibility of brightening it, but it would still be attended with the great inconvenience of not resisting leys. We must begin, then, by preparing the cotton as if to dispose it for receiving the Adrianople red; and when it has been brought to the operation of galling, it is to be passed through a solution of iron, more or less charged, according to the nature of the violet required: it is then to be carefully washed, twice maddered, and brightened in a bath of soap.

When a real velvety rich violet is required, it is not to be passed through the solution of iron till it has been previously galled; the iron is then precipitated in a bluish oxyd, which, combined with the red of madder, gives a most brilliant purple, more or less dark according to the strength of the galling and of the ferruginous solution. It is very difficult to obtain an equal colour by this process; and in manufactories, an equal violet is considered as a master-piece of art. It is generally believed, that it is only by well directed manipulations that it is possible to resolve this problem, of so much importance in dyeing. But I am convinced (says our author), that the great cause of the inequality in this dye is, that the iron deposited on the cotton receives an oxydation merely by exposure to the air, which varies in different parts of it. The threads which are on the outside of the hank are strongly oxydated, while those in the inside, removed from the action of the air, experience no change. It thence follows, that the inside of the hank presents a weak shade, while the exterior part exhibits a violet almost black. The means to remedy this inconvenience is, to wash the cotton when it is taken from the solution of iron, and to expose it to the madder moist. The colour will become more equal and velvety. The solvents of iron are almost the same for this colour as for the yellow colour already mentioned.

The following observation may serve to guide the artist in brightening the violet on his cotton. The red of madder and the oxyd of iron deposited on the stuff determine the violet colour. This colour becomes red or blue, according as either of the principles predominates. The dyer knows by experience how difficult it is to obtain a combination which produces the tone of colour desired, especially when it is required to be very full, lively, and durable. This object, however, may be obtained, not only by varying the proportions of the two colouring principles, but also by varying the process of brightening. The only point is to be acquainted with the two following facts; that the soda destroys the iron, while the soap, by strong ebullition, seizes in preference the red of the madder. Hence it is, that the colour may be inclined to red or blue, according as you brighten with one or the other of these mordants. Thus, cotton taken from the madder dye, when washed and boiled in the brightening liquor with $\frac{1}{10}$ths of soap, will give a superb violet; whereas you will obtain only a plum colour in treating it with soda.

The oxyd of iron precipitated on any stuff unites also very advantageously with the fawn colour furnished by astringents; and by varying the strength of mordants, an infinity of shades may be produced. In this case, it is less a combination or solution of principles than the simple mixture or juxta-position of the colouring bodies on the stuff. By means of a boiling heat, we may combine, in a more intimate manner, the oxyd of iron with the astringent principle: and then it is brought to the state of black oxyd, as has been observed by Berthollet. It is possible also to embrown these colours, and to give them a variety of tints, from the bright grey to the deep black, by merely passing the cottons impregnated with the astringent principle thro' a solution of iron. The oxyd is then precipitated itself by the principle which is fixed on the stuff.

An observation, which may become of the utmost value for the art of dyeing, is, that the most usual astringent vegetables all furnish a yellow colour, which has not much brilliancy, but which has sufficient fixity to be employed with advantage. This yellow colour is brightened in the series of vegetables, in proportion as the astringent principle is diminished, and the vivacity of the colour is augmented in the same proportion. It is difficult, then, to obtain yellow colours which are at the same time durable and brilliant. These two valuable qualities are to each other in an inverse ratio: but it is possible to unite the colouring principles in such a manner as to combine splendour with fixity. Green oak bark unites perfectly with yellow weed, and sumach with green citron. It is by this mixture that we may be able to combine with the oxyd of iron vegetable colours, the splendour of which is equal to their durability.

Our author concludes his observations with cautioning the dyer against substituting sumach and the bark of the alder tree or oak for gall when dyeing cotton red. "I can safely assert (says he), that it is impossible to employ these as substitutes, in whatever doses they may be used. The colour is always much paler, poorer, and less fixed. I know that the case is not the same in regard to dyeing wool and silk, in which it may be employed with success; and in giving an account of this difference, I think the cause of it may be found in the nature of the gall-nuts. 1. The acid which they exclusively contain, as Berthollet has proved, facilitates the decomposition of the soap with which the cottons have been impregnated, and the oil then remains fixed in their tissue, and in a greater quantity, as well as in a more intimate combination. 2. The gall-nuts, which owe their development to animal bodies, retain a character of animalisation, which they transmit to the vegetable stuff, and by these means augment its affinities with the colouring principle of the madder; for it is well known of what utility animal substances are to facilitate this combination. This animalisation becomes useless in operating upon woollen or silk."

IRON BANKS, a tract of land on the E. side of the Mississippi, below the mouth of the Ohio.—*Morse.*

IRON-CASTLE, one of the forts of Porto Bello, in S. America, which admiral Vernon took and destroyed in 1739. The Spaniards call it St Philip de todo Fierra.—*ib.*

IRONDEQUAT, called in some maps *Ge Rundegut*, a gulf or bay on the S. side of the Lake Ontario, 4 miles E. of Walker's at the mouth of Genessee river. —*ib.*

IRON MOUNTAINS, GREAT, in the State of Tennessee, extend from the river Tennessee to that of French Broad from S. W. to N. E. farther to the N. E. the range has the name of Bald Mountain, and beyond the Nolachucky, that of Iron Mountains. The Iron Mountains, seems to be the name generally applied to the whole range. It constitutes the boundary between the State of Tennessee, and that of North-Carolina, and extends from near the lead mines, on the Kanhaway, through the Cherokee country, to the south of Chota, and terminates near the sources of the Mobile. The caverns and cascades in these mountains are innumerable.—*ib.*

IRRATIONAL NUMBERS or *Quantities*, are the same as *surds*, for which see ALGEBRA, *Encycl.*

IRREDUCIBLE CASE, in algebra, is used for that case of cubic equations where the root, according to Cardan's rule, appears under an impossible or imaginary form, and yet is real.

It is remarkable that this case always happens, *viz.* one root, by Cardan's rule, in an impossible form, whenever the equation has three real roots, and no impossible ones, but at no time else.

If we were possessed of a general rule for accurately extracting the cube root of a binomial radical quantity, it is evident we might resolve the irreducible case generally, which consists of two of such cubic binomial roots. But the labours of the algebraists, from Cardan down to the present time, have not been able to remove this difficulty. Dr Wallis thought that he had discovered such a rule; but, like most others, it is merely tentative, and can only succeed in certain particular circumstances.

IRVIN *River* is a western head water of the Neus, in N. Carolina.—*Morse.*

ISABEL, ST, one of the islands of Solomon, 200 miles

miles in circumference in the Pacific Ocean, 7° 30′ S. lat. about 160 leagues W. of Lima, discovered by Mendana, 1567, whose inhabitants are cannibals, and worship serpents, toads, and other animals. Their complexion is bronze, their hair woolly, and they wear no covering but round the waist. The people are divided into tribes, and are constantly at war with each other. Bats were seen here, which from one extremity of their wings to the other, measured 5 feet. Dampier, who has the reputation of exactness, says that he saw, in the small island of Sabuda, on the W. coast of Papua, bats as large as young rabbits, having wings 4 feet in extent from one tip to the other.—*ib.*

ISABELLA *Point*, lies on the N. side of the island of St Domingo, and forms the N. E. side of the bay of its name. N. lat. 19° 59′ 10″. This is the port where Columbus formed the first Spanish settlement on the island, and named both it and the point after his patroness Queen Isabella. He entered it in the night, driven by a tempest. It is over-looked by a very high mountain flat at the top, and surrounded with rocks, but is a little exposed to the N. W. wind. The river Isabella which falls into it, is considerable. There are 14 fathoms of water to anchor in. The settlement was begun in 1493, was given up in 1496, when its inhabitants were carried to the city of St Domingo, which originally was called New Isabella. The bay is said to have good anchorage for ships of war. It is about 29 leagues east by north of Cape Francois, measuring in a straight line.—*ib.*

ISCA, or rather *Ica*, with Pisco and Nasca, three towns from which a jurisdiction of Lima in Peru, S. America, has its name. Great quantities of wine are made here and exported to Calao. It also produces excellent olives, either for eating or for oil. The fields which are watered by trenches, yield an uncommon plenty of wheat, maize, and fruits. This jurisdiction is remarkable for spacious woods of carob trees, with the fruit of which the inhabitants feed numbers of asses, for the uses of agriculture, to this and the neighbouring jurisdictions. The Indians who live near the sea apply themselves to fishing, and after salting the fish carry them to a good market in the towns among the mountains.—*ib.*

ISLE OF WIGHT, a county of Virginia, on the south side of James's river, west of Norfolk county, being about 40 miles long and 15 broad, and contains 9,028 inhabitants, including 3,867 slaves. A mineral spring has been discovered near the head of the west branch of Nansemond river, about 10 miles from Smithfield, and 12 from Suffolk. It is much resorted to, and famed for its medicinal qualities.—*ib.*

ISLE ROYAL, on the north-west side of Lake Superior, lies within the territory of the United States north-west of the Ohio, is about 100 miles long, and in many places about 40 broad. The natives suppose that this and the other islands in the lake are the residence of the Great Spirit.—*ib.*

ISLESBOROUGH, a township in Hancock county, Maine, formed by Long-Island, in the centre of Penobscot Bay, 15 miles in length, and from 2 to 3 in breadth. It was incorporated in 1789, contains 382 inhabitants, and is 260 miles N. E. by N. of Boston. —*ib.*

ISLES DE MADAME lie at the south end of Sydney, or Cape Breton Island, on which they are dependant. The largest of these, with Cape Canso, the east point of Nova-Scotia, form the entrance of the Gut of Canso from the Atlantic ocean.—*ib.*

ISLIP, a township of New-York, situated in Suffolk county, Long-Island, east of Huntington, and contains 609 inhabitants; of these 93 are electors, and 35 slaves.—*ib.*

JUAN DE FUCA, a celebrated strait on the north-west coast of America, was surveyed by Captain Vancouver in the Discovery sloop of war, with a view to ascertain whether it leads to any communication between the North Pacific and the North Atlantic Oceans. As they advanced within the opening of the strait, their progress was greatly retarded by the number of inlets into which the entrance branched in every direction; and most of these were examined by the boats, which were frequently absent from the ships on this service for several days together. In the midst of their labours, they were surprised by the sight of two Spanish vessels of war, employed, like themselves, in surveying this inlet, the examination of which had been begun by them in the preceding year. Measures of mutual assistance were concerted between the captains of the two nations for the prosecution of the survey, in which each agreed to communicate to the other their discoveries. Not one of the many arms of the inlet, nor of the channels which they explored in this broken part of the coast, was found to extend more than 100 miles to the eastward of the entrance into the strait. After having surveyed the southern coast, on which side a termination was discovered to every opening, by following the continued line of the shore, they were led to the northward, and afterward towards the north-west, till they came into the open sea through a different channel from the strait of Juan de Fuca, by which they had commenced this inland navigation.

Thus it appeared, that the land forming the north side of that strait is part of an island, or of an archipelago, extending nearly 100 leagues in length from S. E. to N. W.; and on the side of this land most distant from the continent is situated Nootka Sound. The most peculiar circumstance of this navigation is the extreme depth of water, when contrasted with the narrowness of the channels. The vessels were sometimes drifted about by the currents during the whole of a night, close to the rocks, without knowing how to help themselves, on account of the darkness, and the depth being much too great to afford them anchorage.

In the course of this survey, the voyagers had frequent communications with the natives, whom they met sometimes in canoes and sometimes at their villages. In their transactions with Europeans, they are described as "well versed in the principles of trade, which they carried on in a very fair and honourable manner." In other respects they were less honest. At one village 200 sea otter skins were purchased of them by the crews of the vessels in the course of a day; and they had many more to sell in the same place, as also skins of bears, deer, and other animals. One party of Indians whom they met had the skin of a young lioness; and these spoke a language different from that used in Nootka Sound. Venison was sometimes brought for sale; and a piece of copper, not more than a foot square, purchased one whole deer and part of another. Among other articles of traffic, two children, six or seven years of age, were offered for sale. The commodities most prized by the natives were fire-arms, copper, and great coats. Beads and trinkets they would only receive as presents, and not as articles of exchange. Many of them were possessed of fire-arms. In one part it is related, that after a chief had received some presents, "he, with most of his companions, returned to the shore; and, on landing, fired several muskets, to shew, in all probability, with what dexterity they could use these weapons, to which they seemed as familiarized as if they had been accustomed to fire-arms from their earliest infancy."

The dresses of these people, besides skins, are a kind of woollen garments; the materials composing which are explained in the following extract:

"The dogs belonging to this tribe of Indians were numerous, and much resembled those of Pomerania, though, in general, somewhat larger. They were all shorn as close to the skin as sheep are in England; and so compact were their fleeces, that large portions could be lifted up by a corner without causing any separation. They were composed of a mixture of a coarse kind of wool, with very fine long hair, capable of being spun into yarn. This gave Captain Vancouver reason to believe, that their woollen cloathing might in part be composed of this material mixed with a finer kind of wool from some other animal, as their garments were all too fine to be manufactured from the coarse coating of the dog alone."

Of other animals alive, deer only were seen in any abundance by our people.

The number of inhabitants computed to be in the largest of the villages or towns that were discovered, did not exceed 600. Captain Vancouver conjectured the small-pox to be a disease common and very fatal among them. Many were much marked; and most of these had lost their right eye. Their method of disposing of their dead is very singular.

"Baskets were found suspended on high trees, each containing the skeleton of a young child; in some of which were also small square boxes filled with a kind of white paste, resembling (says our author) such as I had seen the natives eat, supposed to be made of the saranne root; some of these boxes were quite full, others were nearly empty, eaten probably by the mice, squirrels, or birds. On the next low point south of our encampment, where the gunners were airing the powder, they met with several holes in which human bodies were interred, slightly covered over, and in different states of decay, some appearing to have been very recently deposited. About half a mile to the northward of our tents, where the land is nearly level with high water mark, a few paces within the skirting of the wood, a canoe was found suspended between two trees, in which were three human skeletons.

"On each point of the harbour, which, in honour of a particular friend, I called *Penn's Cove*, was a deserted village; in one of which were found several sepulchres, formed exactly like a centry box. Some of them were open, and contained the skeletons of many young children tied up in baskets: the smaller bones of adults were likewise noticed, but not one of the limb bones could here be found; which gave rise to an opinion, that these, by the living inhabitants of the neighbourhood, were appropriated to useful purposes; such as pointing their arrows, spears or other weapons."

However honourably these people have been represented in their conduct as traders, it appeared on several occasions that it was unsafe to depend on their good-will alone: and some instances occurred, of their making every preparation for an attack, from which they desisted only on being doubtful of the event; yet immediately on relinquishing their purpose, they would come with the greatest confidence to trade, appearing perfectly regardless of what had before been in agitation. The boats, as already noticed, were frequently at a great distance from the ships; and on such occasions, when large parties of Indians have first seen them, they generally held long conferences among themselves before they approached the boats; probably for the purpose of determining the mode of conduct which they judged it most prudent to observe. Captain Vancouver places the entrance of the strait of Juan de Fuca in 48° 20′ N. Lat. and 124° W. Long.

JUAN. St, the capital of California in N. America. N. lat 26° 25′, W. long. 114° 9′.—*Morse.*

Juan, *Fort St*, stands in the province of New Leon, in N. America, on the S. W. side of the Rio Bravo, in the 29th degree of N. latitude and 101st of W. longitude.—*ib.*

JUDITH, POINT, the south-easternmost point of Rhode-Island State, situated on the sea-coast of Washington county, in South-Kingston township.—*ib.*

JUDOSA BAY, in Louisianna, lies in the N. W. corner of the gulf of Mexico. A chain of islands form a communication between it south westward to St Bernard's Bay.—*ib.*

JUGGLERS are a kind of people whose profession has not been often deemed either respectable or useful. Professor Beckmann, however, has undertaken their defence; and in a long and learned chapter in the third volume of his *History of Inventions*, pleads the cause of the practisers of legerdemain; rope-dancers; persons who place their bodies in positions apparently dangerous; and of those who exhibit feats of uncommon strength. All these men he classes under the general denomination of *Jugglers;* and taking it for granted (surely upon no good grounds) that every useful employment is full, he contends, that there would not be room on the earth for all its present inhabitants did not some of them practise the arts of *Juggling*.

"These arts (says he) are indeed not unprofitable, for they afford a comfortable subsistence to those who practise them; but their gain is acquired by too little labour to be hoarded up; and in general, these roving people spend on the spot the fruits of their ingenuity; which is an additional reason why their stay in a place should be encouraged. But farther, it often happens, that what ignorant persons first employ, merely as a show, for amusement or deception, is afterwards ennobled by being applied to a more important purpose. The machine with which a Savoyard, by means of shadows, amused children and the populace, was by Lieberkühn converted into a solar microscope; and, to give one example more, the art of making ice in summer, or in a heated oven, enables guests, much to the credit of their hostess, to cool the most expensive dishes. The Indian discovers precious stones, and the European, by polishing, gives them a lustre.

"But, if the arts of juggling ferved no other end than to amufe the moft ignorant of our citizens, it is proper that they fhould be encouraged for the fake of thofe who cannot enjoy the more expenfive deceptions of an opera. They anfwer other purpofes, however, than that of merely amufing: they convey inftruction in the moft acceptable manner, and ferve as an agreeable antidote to fuperftition, and to that popular belief in miracles, exorcifm, conjuration, forcery, and witchcraft, from which our anceftors fuffered fo feverely."

Surely this reafoning, as well as the caufe in which it is brought forward, is unworthy of the learning of Beckmann. It is indeed true, that jugglers fpend their money freely, and that their arts afford them the means of fubfiftence; but it is very feldom, as our author muft know, that they fubfift either comfortably or innocently. Is it innocent to entice the ignorant and labouring poor, by ufelefs deceptions, to part with their hard earned pittance to idle vagabonds? or is the life of thofe vagabonds comfortable, when it is paffed amid fcenes of the moft grovelling diffipation? Jugglers fpend indeed their money, for the moft part, on the fpot where it is gained; but they fpend it in drunkennefs, and other feducing vices, which corrupt their own morals and the morals of all with whom they affociate; and therefore their ftay in a place fhould certainly *not* be encouraged. Could it be proved that the folar microfcope would never have been invented, had not a Savoyard juggler contrived a fimilar machine to amufe children and the rabble, fome ftrefs might be laid on the fervice which fuch wretches have rendered to fcience: but where is the man that will fuppofe the philofophy of Bacon and Newton to reft upon the arts of juggling? or who confiders the refinements of fcience as of equal value with the morals of the people? There is, at the moment in which this article is drawing up, a fellow exhibiting, before the windows of the writer's chamber, the moft indecent fcenes by means of puppets, and keeping the mob in a conftant roar. Is he innocently employed? or will any good man fay that there is not room for him in the armies which on the Continent are fighting in the caufe of God and humanity?

Our author endeavours to ftrengthen his reafoning by proving, which he does very completely, the antiquity of juggling. "The deception (fays he) of breathing out flames, which at prefent excites, in a particular manner, the aftonifhment of the ignorant, is very ancient. When the flaves in Sicily, about a century and a half before our æra, made a formidable infurrection, and avenged themfelves in a cruel manner for the feverities which they had fuffered, there was amongft them a Syrian named Eunus, a man of great craft and courage, who, having paffed through many fcenes of life, had become acquainted with a variety of arts. He pretended to have immediate communication with the gods; was the oracle and leader of his fellow flaves; and, as is ufual on fuch occafions, confirmed his divine miffion by miracles. When, heated by enthufiafm, he was defirous of infpiring his followers with courage, he breathed flames or fparks among them from his mouth while he was addreffing them. We are told by hiftorians, that for this purpofe he pierced a nut-fhell at both ends, and having filled it with fome burning fubftance, put it into his mouth and breathed through it.

"This deception, at prefent, is performed much better. The juggler rolls together fome flax or hemp, fo as to form a ball about the fize of a walnut; fets it on fire; and fuffers it to burn till it is nearly confumed; he then rolls round it, while burning, fome more flax; and by thefe means the fire may be retained in it for a long time. When he wifhes to exhibit, he flips the ball unperceived into his mouth and breathes through it; which again revives the fire, fo that a number of weak fparks proceed from it; and the performer fuftains no hurt, provided he infpire the air not through the mouth but the noftrils.

"For deceptions with fire the ancients employed alfo naphtha, a liquid mineral oil, which kindles when it only approaches a flame. (See Naphtha, *Encycl.*) Galen informs us, that a perfon excited great aftonifhment by extinguifhing a candle and again lighting it, without any other procefs than holding it immediately againft a wall or a ftone. The whole fecret of this confifted in having previoufly rubbed over the wall or ftone with fulphur. But as the author, a few lines before, fpeaks of a mixture of fulphur and naphtha, we have reafon to think that he alludes to the fame here. Plutarch relates how Alexander the Great was aftonifhed and delighted with the fecret effects of naphtha, which were exhibited to him at Ecbatana. The fame author, as well as Pliny, Galen, and others, has already remarked that the fubftance with which Medea deftroyed Creufa, the daughter of Creon, was nothing elfe than this fine oil. She fent to the unfortunate princefs a drefs befmeared with it, which burft into flames as foon as fhe approached the fire of the altar. The blood of Neffus, in which the drefs of Hercules, which took fire likewife, had been dipped, was undoubtedly naphtha alfo; and this oil muft have been always employed when offerings caught fire in an imperceptible manner.

"In modern times, perfons who could walk over burning coals or red-hot iron, or who could hold red-hot iron in their hands, have often excited wonder. But laying afide the deception fometimes practifed on the fpectators, the whole of this fecret confifts in rendering the fkin of the foles of the feet and hands fo callous and infenfible, that the nerves under them are fecured from all hurt, in the fame manner as by fhoes and gloves. Such callofity will be produced if the fkin is continually compreffed, finged, pricked, or injured in any other manner. Thus do the fingers of the induftrious fempftrefs become horny by being frequently pricked; and the cafe is the fame with the hands of fire workers, and the feet of thofe who walk bare footed over fcorching fand.

"In the month of September 1765, when I vifited (fays our author) the copper-works at Awedal, one of the workmen, for a little drink money, took fome of the melted copper in his hand, and after fhewing it to us, threw it againft a wall. He then fqueezed the fingers of his horny hand clofe to each other; put it a few minutes under his arm-pit, to make it fweat, as he faid; and, taking it again out, drew it over a ladle filled with melted copper, fome of which he fkimmed off, and moved his hand backwards and forwards, very quickly, by way of oftentation. While I was viewing this performance, I remarked a fmell like that of finged horn or leather, though his hand was not burnt. It is highly probable, that people who hold in their hands red hot iron, or who walk upon it, as I faw done at Amfterdam, but

at

Jugglers. at a distance, make their skin callous before, in the like manner. This may be accomplished by frequently moistening it with spirit of vitriol; according to some the juice of certain plants will produce the same effect; and we are assured by others, that the skin must be very frequently rubbed, for a long time, with oil, by which means, indeed, leather also will become horny*."

Our author then proves, in a very learned manner, that all these tricks were of high antiquity; that the Hirpi, who lived near Rome, jumped through burning coals; that women were accustomed to walk over burning coals at Castabala in Cappadocia, near the temple dedicated to Diana; that the exhibition of balls and cups (see LEGERDEMAIN, *Encycl.*) is often mentioned in the works of the ancients; that in the third century, one Firmus or Firmius, who endeavoured to make himself emperor in Egypt, suffered a smith to forge iron on an anvil placed on his breast; that rope-dancers with balancing poles are mentioned by Petronius and others; and that the various feats of horsemanship exhibited in our circuses passed, in the thirteenth century, from Egypt to the Byzantine court, and thence over all Europe.

Julian, ‖ Iwanee.

JULIAN, ST, a harbour on the coast of Patagonia, in South-America, where ships bound to the Pacific ocean usually touch for refreshment. S. lat. 48° 51', W. long. 65° 10'.—*Morse.*

JULIET, MOUNT, in North-America, lies on the north side of Illinois river, opposite the place where that river is formed by the junction of Theakiki and Plein rivers. The middle of Mount Juliet is in N. lat. 42° 5', W. long. 88° 44'.—*ib.*

JUNGLE, in Bengal, waste land, or land covered with wood and brambles.

JUNIUS, a military township in New-York State, bounded north by Galen, and south by Romulus.—*Morse.*

JUNIUS CREEK, a northern branch of the Little Kanhaway, which interlocks with the western waters of Monongahela river; and which may one day admit a shorter passage from the latter into the Ohio.—*ib.*

IWANEE, a little town near St Jago de Cuba, where a small remnant of the ancient Indians live, who have adopted the manners and language of the Spaniards.—*ib.*

K.

Kaarta.

KAARTA, a kingdom in Africa, through which Mr Park passed in his route from the Gambia to the Niger. He describes the country as consisting either of sandy plains or rocky hills; but, from his account, the level part seems to be the most extensive. The natives are negroes, of whom many, though converted to the Mahomedan faith, or rather to the ceremonial part of the Mahomedan religion, retain all their ancient superstitions, and even drink strong liquors. They are called Johers or Jowers, and in Kaarta form a very numerous and powerful tribe. One of these men undertook to conduct our author to Kemmoo, the capital of the kingdom, and alarmed him not a little by his superstitious ceremonies.

We had no sooner (says Mr Park) got into a dark and lonely part of the first wood, than he made a sign for us to stop, and taking hold of a hollow piece of bamboo, that hung as an amulet round his neck, whistled very loud, three times. I confess I was somewhat startled, thinking it was a signal for some of his companions to come and attack us; but he assured me that it was done merely with a view to ascertain what success we were likely to meet with on our present journey. He then dismounted, laid his spear across the road, and having said a number of short prayers, concluded with three loud whistles; after which he listened for some time, as if in expectation of an answer, and receiving none, told us we might proceed without fear, for there was no danger."

White men were strangers in the kingdom of Kaarta; and the appearance of our author had on some of the natives the effect which ignorant people, in this country, attribute to ghosts. "I had wandered (says he) a little from my people, and being uncertain whether they were before or behind me, I hastened to a rising ground to look about me. As I was proceeding towards this eminence, two negro horsemen, armed with muskets, came galloping from among the bushes: on seeing them I made a full stop; the horsemen did the same, and all three of us seemed equally surprised and confounded at this interview. As I approached them their fears increased, and one of them, after casting upon me a look of horror, rode off at full speed; the other, in a panic of fear, put his hand over his eyes, and continued muttering prayers until his horse, seemingly without the rider's knowledge, conveyed him slowly after his companion. About a mile to the westward, they fell in with my attendants, to whom they related a frightful story: it seems their fears had dressed me in the flowing robes of a tremendous spirit; and one of them affirmed, that when I made my appearance, a cold blast of wind came pouring down upon him from the sky like so much cold water."

Kaarta, ‖ Kaats.

At Kemmoo our traveller was graciously received by the king; who honestly told him, however, that he could not protect him, being then engaged in war with the king of BAMBARRA (See SEGO in this *Supplement*); but he gave him a guard to JARRA, the frontier town of the neighbouring kingdom of Ludamar. The origin and issue of this war between Kaarta and Bambarra, of which Mr Park gives a full account, shews the folly of attempting to liberate the negroes from slavery till civilization and Christianity be introduced into Africa. Major Rennel places Kemmoo, the capital of Kaarta, in 14° 15' N. Lat. and 7° 20' W. Lon.

KAATS' BAAN, in New-York State, lies on the west bank of Hudson's river, 7 miles southerly from Kaats' Kill, and 11 N. E. by N. from Esopus.—*Morse.*

Kaats' Kill, or *Catskill*, a small village of 30 or 40 houses and stores, in the State of New-York, situated on the west side of Hudson's river, about 100 rods from its bank; 5 miles south of Hudson city, and 125 north of New York. It has the appearance of a thriving place. and it is in contemplation to erect buildings on a marshy point, on the margin of the river, for the advantage of deeper water. The creek on which the stores now stand being too shallow. The township of this name contains 1,980 inhabitants, of whom 343 are electors, and 305 slaves.—*ib.*

Kaats' Kill *Mountains*, in the vicinity of the above town on the west bank of Hudson's river, which make a majestic appearance. These are the first part of the chain of mountains called the Allegany, or Appalachian mountains.—*ib.*

KABOBIQUAS, a nation in south Africa, who had never seen a white man till 1785, that they were visited by M. Vaillant. Intimation had been given of his approach by some of the tribes through whose country he had previously passed; and every thing that had been said of his colour, his fusees, and his equipage, bore the character of the most enthusiastic exaggeration. The curiosity of the people was wound up to the highest pitch; and as soon as they saw his company at a distance, the whole horde quitted the kraal, and ran with eagerness to meet him. Not being able to believe their eyes in regard to what they saw, they endeavoured to obtain more satisfaction by touching him. They felt his hair, hands, and almost every part of his body. His beard, above all, astonished them to an inconceivable degree. More than thirty persons came in succession, and half unbuttoned his clothes. They all imagined him to be a hairy animal; and supposed, without doubt, that his body was covered with hair as long as that on his chin; but finding this not to be the case, they were astonished, and confessed, with the openness of savages, that they had never seen the like in any man of their country. The little children, terrified at his appearance, hid themselves behind their mothers. When he attempted to lay hold of any of them, in order to caress them, they sent forth loud cries, as a child would do in Europe who should see a negro for the first time.

The grown up people, however, were soon reconciled to his appearance, and even the children were bribed by small bits of sugar candy. The chief of the horde showed him every mark of attachment. He was a man advanced in life, and of a majestic figure. He wore a long mantle, which hung from his shoulders to the ground, and which, formed of four jackal skins joined together, was bordered at the sides with that of a hyæna. His left hand wanted two joints of the little finger, which he said, were amputated in his infancy to cure him of a severe illness.

This custom of savages, who, to relieve a man from pain, add new sufferings to his evils, affords a vast field for reflection. Mr Paterson, another African traveller, tells us, that he observed instances of the same practice among a horde at the mouth of Orange-river; which is not improbable. However absurd a custom may be, savage tribes when they are neighbours, may borrow it from each other; but that it should be common among the islanders of the South Sea, who, since their country was first inhabited, had never seen strangers before Cook and Bougainville, is truly astonishing. Our author was very desirous of interrogating minutely the people of the horde on this subject. He wished also to propose some questions to them respecting other customs which appeared singular; but difficulties increased the more he advanced into the country. The Kabobiquas spoke a particular language; and this dialect, though accompanied with the clapping noise of the Hottentots, was understood only by the Koraquas, who, on account of their vicinity, kept up some intercourse with them. The case was the same with the language of the Koraquas, in regard to their neighbours the Nimiquas; and nothing reached our author's ear till it had passed through four different months. The consequence was, that when he asked any thing, the answer had frequently no relation to the question; and for this inconveniency no remedy could be found.

The same desire for trinkets to ornament their dress prevailed among the Kabobiquas as among the other hordes which Vaillant had visited; and in one day he purchased twenty oxen for things of that kind of no value. The chief, however, had set his affections on a razor; and just when our author and he were treating about it, a shot was fired near them, which was instantly followed by the most frightful cries. "Rushing instantly from my tent (says M. Vaillant) to enquire what was the cause of this noise, I saw a Kabobiqua flying as fast as he could from one of my hunters, while, at the distance of a hundred paces farther, three men were making the most lamentable clamour, and near them was a young girl lying on the ground. I made a signal to my hunter to approach me; but the report of the shot, and the howling of the three men, had already spread alarm throughout the horde. Some cried out treachery; others ran to their arms; and I now imagined that I was about to be massacred, with my whole company, and that I should be obliged to arm them in my defence. My situation was the more critical, as neither I, nor any person in the kraal, knew what was the cause of this confusion; and if I had known, how could I have explained it?

"Under this embarrassment, I took the chief by the hand, and advanced with him towards the horde. Fear was painted in his countenance; tears began to drop from his eyes; and he spoke to me with great vivacity. He imagined, no doubt, that he was betrayed. He complained to me. and accused my people of perfidy; yet he readily followed me.

"As I was without arms, and presented myself with the chief, I was received with confidence, and my appearance seemed, in some measure, to calm their perturbation. My people, who had seen me direct my course towards the kraal, hastened thither after me, to protect me; and their number overawed the multitude. At length the whole mystery was cleared up, and we learned what had occasioned the tumult.

"A Kabobiqua having met one of my hunters, who was returning with his fusee, wished to examine it, and begged him to shew it to him. In handling it, however, he accidentally touched the trigger; it instantly went off; and the savage, frightened by the unexpected explosion, threw down the fusee, and ran away as fast as he could.

"At that time, three men of the horde and a young girl happened unluckily to be standing, at the distance of a hundred paces, in the direction of the piece. The

Kabobiquas. latter received a single grain of shot in the cheek; and the others a few grains in the legs and thighs. The author of the misfortune confirmed this explanation; tranquillity was soon restored; the savages deposited their arms; and I was surrounded only by friends as before.

"Nothing remained but to enquire into the state of the wounded, and to give them every assistance in my power. Without loss of time, therefore, I repaired, still accompanied by the chief, to the place where they were. By the way we met the young girl, who was returning from the kraal, bathed in tears. The cause of her uneasiness was a grain of lead, which had, however, penetrated so little, that I forced it out by only pressing the part with my fingers. With regard to the three men, they lay rolling on the ground, howling in a most frightful manner, and exhibiting every symptom of despair.

"I was astonished at their consternation, and could not conceive how men inured to sufferings should be so much affected by a few small punctures, the pain of which could have scarcely drawn tears from an infant. They at length told me the cause of their wailings. These savages, accustomed to poison their arrows, imagined that I had in like manner poisoned the lead with which they were wounded. They had, therefore, given themselves up as lost, and expected in a few moments to expire."

It was with great difficulty that our author could convince them that they had nothing to fear. He shewed them in the flesh of his own leg a dozen of shots of lead; but they were not satisfied till one of the most intelligent of his Hottentots, taking from his shot bag a few grains of lead, and shewing them to the three men, immediately swallowed them. This conclusive argument produced the desired effect. The cries of the wounded men instantly ceased; serenity again appeared in their faces; and their wounds were no more mentioned.

The Kabobiquas have neither the flat nose nor plump cheeks of the Hottentots. Their skin also has not that bastard colour, which, being neither black nor white, renders them odious to both races; nor do they besmear their bodies with those disgusting fat substances, on account of which one cannot approach them without being bedaubed with their filth, or acquiring an offensive smell. In stature they are as tall as the Caffres, and their colour is equally black. Their hair, which is exceedingly short, and much curled, is ornamented with small copper buttons, arranged with great art and symmetry. Instead of that apron made of a jackal's skin, employed by the Hottentot to cover what modesty bids him conceal, the Kabobiquas use a round piece of leather, the edge of which is ornamented with a small indented circle of copper, and which is divided into different compartments by rows of glass beads of various colours, all proceeding from the centre, and diverging towards the circumference, like the rays in our images of the sun.

This kind of veil is made fast to the groin by means of a girdle; but as it is only four inches in diameter, as it is deranged by the smallest movement, and as they give themselves little uneasiness respecting such accidents, it is very ill suited to the purpose for which it is applied. During the great heats, this small and almost useless apron is the only covering on their bodies. Its being so readily displaced, enabled our author to ascertain that they do not practise circumcision; but it seemed to show also, that, in regard to modesty, their ideas are very different from ours.

Kabobiquas. Though they go thus almost entirely naked, their manners, instead of being licentious, are remarkably chaste. No females can be more prudent or more reserved than their women; and whether from refinement of coquetry, or the effect of prudence, they do not tattoo their faces like their husbands and fathers. They do not even follow their example in ornamenting their hair with copper buttons; and they always go barelegged, though most of them wear sandals.

Their dress consists of an apron that reaches only half down the thigh; a kross which, passing under the arm-pits, is tied on the breast; and a long mantle like that of the men. The mantle is made of skins not deprived of the hair; and the kross of tanned leather, prepared like that used for gloves in Europe.

With regard to glass beads, they wear them as bracelets. They form them also into necklaces, which descend in different rows to the pit of the stomach; and they suspend from their girdles several strings of them, which fall down their thighs below the apron.

These ornaments being very durable, the habit of seeing them renders the women almost indifferent to the pleasure of possessing them. Those they procured from our author afforded at first great satisfaction, on account of their novelty. But when he shewed them scissars and needles, they gave the preference to these articles; and this choice does honour to the good sense of the Kabobiqua ladies. Like their chief, they set a higher value on utility than ornament.

Before our author's arrival among them, the Kabobiquas were acquainted with the use of tobacco through the means of some of the tribes more contiguous to the Cape. It was, however, a luxury which they could seldom enjoy; and so indifferent were they about it, that if it were not brought to them, they would not go a step to procure it. This indifference, about an article which is eagerly sought for by all the tribes of Hottentots, seemed to shew that there are traits in the character of the Kabobiquas which distinguish them from their southern neighbours. The case was the same as to strong liquors, on which they set no great value; and though there were among them some few individuals disposed to relish them, the greater number absolutely refused them.

"If the contents of my flasks (says Vaillant) gave them little satisfaction, they were, however, much captivated with the flasks themselves. These transparent bottles excited their admiration in the highest degree. They called them *solid water;* for, notwithstanding the heat of the climate, these savages had seen ice on the summits of the mountains by which they are surrounded; and they entertained no doubt that the glass of my flasks was water, which I had rendered solid by magic, and which I prevented their fires from melting. As it was impossible for me to explain this matter, I did not attempt to undeceive them: and besides, with what advantage would it have been attended? I suffered them, therefore, to continue in their error, and contented myself with conferring on them an obligation, by giving them all the empty bottles for which I had no use.

"On their part, they vied with each other in shewing

Kabobiquas.

ing their generosity towards me; and I must indeed allow, that I never saw a nation so disinterested. Every night they brought to my camp a considerable quantity of milk; and they never came to spend the evening with my people, without bringing some sheep to regale them. I have seen many of them give away gratuitously, and without receiving any thing in return, part of their herds and their flocks; and, when I departed, there were many persons in my caravan who possessed both sheep and oxen, which they had received as a pure gift."

With this benevolent disposition, the Kabobiquas have also a martial character. Their weapons are poisoned arrows, and a lance with a long iron point, but different from the assagay of the Hottentots. In battle, their defensive armour consists of two bucklers; the one of a size sufficient to cover the whole body of the combatant; the other much smaller. They are both made of skins exceedingly thick, and proof against arrows.

The courage which the Kabobiquas display in combat is particularly exercised in their hunting excursions, and, above all, against carnivorous animals. Intrepid, however, as it may be to attack the elephant and the rhinoceros, these species of animals are not objects of their vengeance; because, living upon grass and herbs, they have nothing to apprehend from them, either for themselves or their cattle. But the tiger, lion, hyæna, and panther, being enemies of a different kind, they declare against them implacable war, and pursue them without remission.

Of the spoils of these destructive animals they form their bucklers, girdles, sandals, krosses, mantles, &c. They consider it as a mark of honour to wear them; and they set a much higher value upon them than upon the skin of the rhinoceros or of the elephant. If they sometimes hunt the latter, it is only as objects of food; and they employ to catch them those concealed pits, which are the usual snares of the Hottentots: but this method, which requires both patience and labour, is very little suited to a people so brave and enterprising as the Kabobiquas.

As they possess so bold and resolute a character, one might be induced to believe that they are ferocious and intractable. Among all the African nations, however, which our author visited, he never knew one that so much practised obedience and subordination.

The chief here is not, as in other tribes, a principal among his equals; he is a sovereign in the midst of his subjects, a master surrounded by his slaves. A word, a gesture, or a look, is sufficient to procure him obedience. Whatever be his orders, they are never contradicted; and the case is the same in every particular family. What the chief is to the horde, the father is to his children. His commands are absolute; and he exercises regal power at home, while he obeys elsewhere.

Though the tribe was very numerous, the wisdom with which it was ruled, and the good order that prevailed, announced, in the man by whom it was governed, an intelligence superior to that of all the savages our author had before seen; for he had not then visited the Houzouanas. The habitation of this chief was suited to his supreme dignity. It was, indeed, a hut only, like those of his subjects, and, like them covered with the skins of animals; but it was much larger, as well as more elevated; and around it were six others, occupied by his family, and destined for them alone.

Kabobiquas, Kajaaga.

The natural dryness of the country inhabited by the Kabobiquas obliges them to dig wells, for their own use as well as for their cattle; but as the same cause often dries up these wells, they are then forced to remove, and to seek elsewhere a soil more abundant in springs; for Fish-River, though considerable in the rainy season, is often, during the great heats, entirely destitute of water.

The long journeys which these too frequent emigrations compel them to undertake, and the intercourse which they thence have with other nations, must necessarily inspire them with ideas unknown to the settled tribes; and it would not be unnatural to suppose, that to this extension of ideas are they indebted for that superiority of intelligence which elevates them above their neighbours.

Of the religion of the Kabobiquas, our author talks very inconsistently, and like a true philosopher of the French school. "Of all the African nations (says he), they are the only people among whom I found any idea, however confused a one, of the existence of a Deity. I do not know whether it be from their own reflection, or the communications of other tribes, that they have acquired this sublime knowledge, which would alone bring them near to a level with polished nations; but they believe, as far as I have been able to learn from my people, that beyond the stars there exists a Supreme Being, who made and who governs all things. I must however observe, that on this subject their ideas are vague, barren, and unproductive. They have no conception of the future existence of the soul, or of rewards and punishments in another life; in short, they have neither worship, sacrifices, ceremonies, nor priests, and are total strangers to what we call religion."

This is impossible. A people believing in a Supreme Being, who made and who governs all things, *may* indeed be without *sacrifices*, *ceremonies*, and *priests*; but such a people cannot avoid *wishing*, that the Being who governs all things may protect them. Such a wish is a prayer; and surely he who prays is no stranger to religion. M. Vaillant places the country of the Kabobiquas between 23° and 25° S. Lat. and 16° 25′ and 19° 25′ Long. east from Paris.

KAHNONWOLOHALE, the principal village of the Oneida Indians, in which is Oneida Castle, about 20 miles south of west from Whitetown, and 12 west of Paris. There is but one framed house in this village. Their habitations are but a small improvement upon the ancient *wigwams*; and are scattered sparsely throughout an enclosure of several miles in circumference, within which they keep their cattle, horses, and swine, and without, plant their corn and sow their grain.—*Morse.*

KAJAAGA, an African kingdom, called by the French *Gallam*, is bounded on the south-east and south by Bambouk; on the west, by Bondou and Foota Torra; and on the north, by the river Senegal. The air and climate (says Mr Park) are more pure and salubrious than at any of the settlements towards the coast; the face of the country is every where interspersed with a pleasing variety of hills and valleys; and the windings of the Senegal river, which descends from the rocky

hills

hills of the interior, make the ſcenery on its banks very picturefque and beautiful.

The inhabitants are called Serawoollies, or (as the French write it) *Seracolets*. Their complexion is a jet black: they are not to be diſtinguiſhed in this reſpect from the Jaloffs.

The government is monarchical; and the regal authority, from what I experienced of it, ſeems to be ſufficiently formidable. The people themſelves, however, complain of no oppreſſion; and ſeemed all very anxious to ſupport the king in a conteſt he was going to enter into with the ſovereign of Kaſſon. The Serawoollies are habitually a trading people; they formerly carried on a great commerce with the French in gold and ſlaves, and ſtill maintain ſome traffic in ſlaves with the Britiſh factories on the Gambia. They are reckoned tolerably fair and juſt in their dealings, but are indefatigable in their exertions to acquire wealth, and they derive conſiderable profits by the ſale of ſalt and cotton cloth in diſtant countries. When a Serawoolli merchant returns home from a trading expedition, the neighbours immediately aſſemble to congratulate him upon his arrival. On theſe occaſions the traveller diſplays his wealth and liberality, by making a few preſents to his friends; but if he has been unſucceſsful, his levee is ſoon over; and every one looks upon him as a man of no underſtanding, who could perform a long journey, and (as they expreſs it) *bring back nothing but the hair upon his head.*

Their language abounds much in gutturals, and is not ſo harmonious as that ſpoken by the Foulahs: it is, however, well worth acquiring by thoſe who travel through this part of the African continent; it being very generally underſtood in the kingdoms of Kaſſon, Kaarta, Ludamar, and the northern parts of Bambara. In all theſe countries the Serawoollies are the chief traders.

Joag, the frontier town of this kingdom as you enter it from Pi?ania, may be ſuppoſed, on a groſs computation, to contain two thouſand inhabitants. It is ſurrounded by a high wall, in which are a number of port holes, for muſquetry to fire through in caſe of an attack. Every man's poſſeſſion is likewiſe ſurrounded by a wall; the whole forming ſo many diſtinct citadels; and amongſt a people unacquainted with the uſe of artillery, theſe walls anſwer all the purpoſes of ſtronger fortifications. To the weſtward of the town is a ſmall river, on the banks of which the natives raiſe great plenty of tobacco and onions. Mr Park was in this town plundered of half his effects by order of the king, becauſe forſooth he had neglected to pay the accuſtomed duties before he entered the kingdom; and it required a good deal of addreſs to prevent himſelf and his attendants from being made ſlaves; a ſtate to which the law, it was ſaid, condemned them for the commiſſion of this unintended crime. He was at laſt reſcued from Joag by a nephew of the king of Kaſſon. Joag is placed by Major Rennel in 14° 25′ N. Lat. and 9° 46′ W. Long.

KAINSI is the name given by the Hottentots to a particular ſpecies of antelope, of which, according to Vaillant, no author has yet given a perfect deſcription. It is called by the Dutch *klip-ſpringer*, on account of the eaſe with which it leaps from rock to rock; and indeed of all the antelopes there is no one equal to it in agility. It is about the ſize of a kid of a year old, and of a yellowiſh grey colour; but its hair has this peculiarity, that, inſtead of being round, pliable, and firm, like that of moſt other quadrupeds, it is flat, harſh, and ſo little adherent to the ſkin, that the ſlighteſt friction makes it fall off. Nothing is more eaſy, therefore, than to deprive this animal of its hair: dead or alive it is the ſame; to rub, or even to touch the animal, is ſufficient. Another peculiarity of this ſingular hair is its being extremely fragile; ſo that if you take a tuft of it between your fingers, and twiſt it with the other hand, it will break like the barbs of a feather. This property, however, belongs not excluſively to the hair of the kainſi; for our author ſays he has obſerved it in the hair of other quadrupeds, which in the ſame manner live among the rocks.

This antelope differs from the other ſpecies alſo in the ſhape of the foot, which, inſtead of being pointed like theirs, is rounded at the end; and as it is always accuſtomed, both in leaping and walking, to tread with the point of the hoof, without reſting at all on the heel, it leaves a print diſtinguiſhable from that of any other antelope in Africa. Its fleſh is exquiſitely flavoured, and much ſought after, particularly by the hunters.

The chace of the kainſi is very amuſing. It is true, it is ſcarcely poſſible to hunt it down with dogs, as it ſoon eſcapes them by means of its inconceivable agility, and gets out of their reach on the point of ſome detached rock, where it will remain whole hours ſafe from all purſuit, and ſuſpended, as it were, above the abyſs. But in this ſituation it is excellently placed for the arrow or the ball of the huntſman; who is commonly certain of ſhooting it at pleaſure, though he is not always able to come at it when killed. We ſhall give our author's account of a chace of the kainſi in his own words.

"I was hunting (ſays he) one of theſe animals, when, from the nature of the place, it found itſelf ſo preſſed by my dogs, as to be on the point of being run down and taken. There were apparently no means of eſcape; ſince before it was a vaſt perpendicular rock, by which its courſe was neceſſarily ſtopped. In this wall, however, which appeared to me perfectly ſmooth, was a little ridge, projecting at moſt not above *two inches*, which the kainſi quickly perceived, and, leaping upon it, to my great aſtoniſhment kept itſelf *firm* (A). I imagined, that at any rate it muſt ſoon tumble down; and my dogs, too, ſo fully expected it, that they ran to the bottom of the rock, to be ready to catch it when it fell. To haſten its fall, I endeavoured to haraſs it, and make it loſe its equilibrium; and for this purpoſe I pelted it with ſtones. All at once, as if gueſſing my deſign, it collected its whole ſtrength, bounded over my head, and, falling a few paces from me, darted away with the utmoſt ſpeed. Notwithſtanding the rapidity of its flight, it would have been eaſy for me to have ſhot it; but its leap had ſo ſurpriſed and amuſed me, that I gave it its life." This was generous, if the ſtory be true.

KAMTSCHATKA is inhabited by a people, who are repreſented in the *Encyclopædia* as poſſeſſing almoſt every quality that can diſgrace human nature. We think

(A) This we think incredible.

Kamtschatka.

think it incumbent upon us to acknowledge, in this place, that a much more favourable picture of them is drawn by La Perouse who visited Kamtschatka in September 1787. The Russian governor made the commodore and his officers remark the promising appearance of several small fields of potatoes, of which the seed had been brought from Irkoutsk a few years before; and purposed to adopt mild, though infallible means, of making farmers of the Russians, Cossacks, and Kamtschadales. The small-pox in 1769 swept away three-fourths of the individuals of the latter nation, which is now reduced to less than four thousand persons, scattered over the whole of the peninsula; and which will speedily disappear altogether, by means of the continual mixture of the Russians and Kamtschadales, who frequently intermarry. A mongrel race, more laborious than the Russians, who are only fit for soldiers, and much stronger, and of a form less disgraceful to the hand of nature, than the Kamtschadales, will spring from these marriages, and succeed the ancient inhabitants. The natives have already abandoned the *yourts*, in which they used to burrow like badgers during the whole of the winter, and where they breathed an air so foul as to occasion a number of disorders. The most opulent among them now build *isbas*, or wooden houses, in the manner of the Russians. They are precisely of the same form as the cottages of our peasants; are divided into three little rooms; and are warmed by a brick stove, that keeps up a degree of heat (A) insupportable to persons unaccustomed to it. The rest pass the winter, as well as the summer, in *balagans*, which are a kind of wooden pigeon-houses, covered with thatch, and placed upon the top of posts twelve or thirteen feet high, to which the women as well as the men climb by means of ladders that afford a footing very insecure. But these latter buildings will soon disappear; for the Kamtschadales are of an imitative genius, and adopt almost all the customs of their conquerors. Already the women wear their hair, and are almost entirely dressed, in the manner of the Russians, whose language prevails in all the *ostrogs;* a fortunate circumstance, since each Kamtschadalian village spoke a different jargon, the inhabitants of one hamlet not understanding that of the next. It may be said in praise of the Russians, that though they have established a despotic government in this rude climate, it is tempered by a mildness and equity that render its inconveniences unfelt. They have no reproaches of atrocity to make themselves, like the Spaniards in Mexico and Peru. The taxes they levy on the Kamtschadales are so light, that they can only be considered as a mark of gratitude towards the sovereign, the produce of half a day's hunting acquitting the imposts of a year. It is surprising to see in cottages, to all appearance more miserable than those of the most wretched hamlets in our mountainous provinces, a quantity of specie in circulation, which appears the more considerable, because it exists among so small a number of inhabitants. They consume so few commodities of Russia and China, that the balance of trade is entirely in their favour, and that it is absolutely necessary to pay them the difference in rubles. Furs at Kamtschatka are at a much higher price than at Canton; which proves, that as yet the market of Kiatcha has not felt the advantageous effect of the new channel opened in China.

Our author compares Kamtschatka, with respect to climate and soil, to the coast of Labrador in the vicinity of the Straits of Belle-Isle; but the men, like the animals, are there very different. The Kamtschadales appeared to him the same people as those of the bay of Castries, upon the coast of Tartary. Their mildness and their probity are the same, and their persons are very little different. They ought then no more to be compared to the Esquimaux Indians, than the sables of Kamtschatka to the martins of Canada.

The Greek religion has been established among the Kamtschadales without persecution or violence, and with extraordinary facility. The vicar of Paratounka is the son of a Kamtschadale and of a Russian woman. He delivers his prayers and catechism with a tone of feeling very much to the taste of the aborigines, who reward his cares with offerings and alms, but pay no tythes. The canons of the Greek church permitting priests to marry, we may conclude that the morals of the country clergymen are so much the better. "I believe them, however (says Perouse), to be very ignorant; and do not suppose, that for a long time to come they will stand in need of greater knowledge. The daughter, the wife, and the sister of the vicar, were the best dancers of all the women, and appeared to enjoy the best state of health. The worthy priest knew that we were good Catholics, which procured us an ample aspersion of holy water; and he also made us kiss the cross that was carried by his clerk; these ceremonies were performed in the midst of the village. His parsonage-house was a tent, and his altar in the open air; but his usual abode is Paratounka, and he only came to St Peter and St Paul's to pay us a visit."

The people of Kamtschatka have inured themselves to the extremes of heat and cold. It is well known, that their custom in Europe, as well as in Asia, is to go into vapour baths, come out covered with perspiration, and immediately roll themselves in the snow. The *ostrog* of St Peter had two of these public baths, into which our author went before the fires were lighted. They consist of a very low room, in the middle of which is an oven constructed of stones, without cement, and heated like those intended to bake bread. Its arched roof is surrounded by seats one above another, like an amphitheatre, for those who wish to bathe, so that the heat is greater or less according as the person is placed upon a higher or lower bench. Water thrown upon the top of the roof, when heated red hot by the fire underneath, is converted instantly into vapour, and excites the most profuse perspiration. The Kamtschadales have borrowed this custom, as well as many others, from their conquerors; and ere long the primitive character that distinguished them so strongly from the Russians will be entirely effaced.

Our author describes the bay of Avatscha as the finest, the most convenient, and the safest, that is to be met with in any part of the world. The entrance is narrow, and ships would be forced to pass under the guns of the forts that might be easily erected. The

 bottom

(A) Not less than thirty degrees of Reaumur's thermometer.

bottom is mud, and excellent holding ground. Two vast harbours, one on the eastern side, the other on the western, are capable of containing all the ships of the French and English navy. The rivers of Avatscha and Paratounka fall into this bay, but they are choaked up with sand-banks, and can only be entered at the time of high water. The village of St Peter and St Paul is situated upon a tongue of land, which, like a jetty made by human art, forms behind the village a little port, shut in like an amphitheatre, in which three or four vessels might lie up for the winter. The entrance of this sort of bason is more than twenty-five toises wide; and nature can afford nothing more safe or commodious. On its shore the governor proposed to lay down the plan of a city, which some time or other will be the capital of Kamtschatka, and perhaps the centre of an extensive trade with China, Japan, the Phillippines, and America. A vast pond of fresh water is situated northward of the site of this projected city; and at only three hundred toises distance run a number of streamlets, the easy union of which would give the ground all the advantages necessary to a great establishment. Of these advantages Mr Kasloff understood the value; "but first (said he a thousand times over) we must have bread and hands, and our stock of both of them is very small." He had, however, given orders, which announced a speedy union of the other *ostrogs* to that of St Peter and St Paul, where it was his intention immediately to build a church. By observation, St Peter and St Paul was found to be in 53° 1′ N. Lat. and 156° 30′ E. Long. from Paris.

KANAWA, or *Kanhawa*, a large mountainous county on the western line of Virginia, having the Ohio river on the north-west, and Kentucky west. The population of this county is included in Green Briar, being 6,015 inhabitants, including 319 slaves. About 7 miles from the mouth of Elk river in this county, is a burning spring, capacious enough to hold 40 gallons. A bituminous vapour constantly issues from it, which agitating the sand around it, gives it the appearance of a boiling spring. On presenting a torch within 18 or 20 inches of the mouth, it flames up in a column, 4 or 5 feet in height, and about 18 inches diameter, and which sometimes burns 20 minutes, and at other times has continued 3 days. General Clarke kindled the vapour, staid about an hour, and left it burning.—*Morse.*

KANAWAGERES, an Indian village on the west side of Genessee river, 4 miles west-south-west of Hartford in the Genessee country in New-York.—*ib.*

KANEM, is the name given by Edrisi to the kingdom of Bornou in Africa, of which the reader will find some account in the *Encyclopædia*. In some particulars, however, that account is incorrect. The kingdom of Bornou or Kanem must extend farther east and farther north than it is there said to do; for according to the latest and best accounts, its capital stands in Lat. 24° 32′ Long. 22° 57′. The empire is said to be very extensive; and if it be true, as we learn from the proceedings of the African Association, that its sovereign is more powerful than the Emperor of Morocco, the people cannot be such absolute brutes, as we have represented them in the article referred to; for the sovereign of brutes would have no power. The truth, however is, that very little is yet known in Europe of Bornou or its inhabitants.

KANHAWAY, GREAT, a river of Virginia of considerable note for the fertility of its lands, and still more as leading towards the head waters of James's river. But it is doubtful whether its great and numerous rapids will admit a navigation, but at an expense to which it will require ages to render its inhabitants equal. The great obstacles begin at what are called the Great Falls, 90 miles above the mouth, below which are only 5 or 6 rapids, and these passable with some difficulty even at low water. From the falls to the mouth of Green Briar is 100 miles. It is 280 yards wide at its mouth. The head waters of this river are in the western part of North Carolina, in the most easterly ridge of the Alleghany or Appalachian mountains, and south of the 36th degree of latitude. Its head branches encircle those of the Holston, from which they are separated by the Iron Mountain, through which it passes 10 miles above the lead mines. About 60 miles from Little river it receives Green Briar river from the east, which is the only considerable tributary stream in all that distance. About 40 miles below the mouth of Green Briar river, in Virginia, in the Kanhaway, is a remarkable cataract. A large rock, a little elevated in the middle, crosses the bed of the river, over which the water shoots, and falls about 50 feet perpendicularly, except at one side where the descent is more gradual. The great Kanhaway is 196 miles below Pittsburg, and is navigable most of the year; and a waggon road may be made through the mountain, which occasions the falls, and by a portage of a few miles only, a communication may be had between the waters of Great Kanhaway and Ohio, and those of James's river in Virginia. Down this river great quantities of goods are conveyed up the Kentucky river, others on horseback or in waggons to the settled part, and sold on an average, at 100 per cent. advance.—*Morse.*

KANHAWAY, LITTLE, a small navigable river of Virginia, which is 150 yards wide at its mouth, and is navigable 10 miles only. Perhaps its northerly branch, called Junius Creek, which interlocks with the western waters of Monongahela, may one day admit a shorter passage from the latter into the Ohio.—*ib.*

KANT (Immanuel), Royal Professor of Morals and Metaphysics in the University of Königsberg, is considered by his admirers as the greatest philosopher that Germany ever produced. Were we to form an estimate of his merits from the different views that have been given in English of his celebrated system, we certainly should not consider him as entitled to that character; for those views are obscured by new and uncouth terms, and are altogether wrapt up in a style which approaches nearer to jargon than to the luminous composition of a man who thinks with clearness and precision. We readily admit, that it is very difficult to translate a novel system of metaphysics from one language into another; for the translator, to perform his task properly, must be not only a complete master of both languages, but also a profound metaphysician; and not one of the translators or abridgers of the works of Kant into our language appears to us possessed of both these qualities. Despairing, from our scanty knowledge of the German language, of performing ourselves what

Kantuffa.

fo many others have failed to perform, we have applied for affiftance to an illuftrious Frenchman, who has refided many years in Germany, who is mafter of both languages, who is a profound metaphyfician, and whofe name, were we at liberty to publifh it, would reflect luftre upon our Work. From him we have reafon to expect a clear and comprehenfive view of the *Critical Philosophy*, as Kant terms his fyftem; but fhould we be difappointed of our expectation, we fhall, under that title, lay before our readers a *fpecimen* of the fyftem from the different views of it which have been publifhed in our own tongue.

KANTUFFA, a fpecies of thorn peculiar to Abyffinia, is thus defcribed by Mr Bruce: The branches ftand two and two upon the ftalk; the leaves are difpofed two and two likewife, without any fingle one at the point, whereas the branches bearing the leaves part from the ftalk: at the immediate joining of them are two thick thorns placed perpendicular and parallel alternately; but there are alfo fingle ones diftributed in all the interftices throughout the branch.

The male plant has a one-leaved perianthium, divided into five fegments, and this falls off with the flower. The flower is compofed of five petals, in the middle of which rife ten ftamina or filaments, the outer row fhorter than thofe of the middle, with long ftigmata, having yellow farina upon them. The flowers grow in a branch, generally between three and four inches long, in a conical difpofition, that is, broader at the bafe than the point. The infide of the leaves are a vivid green, in the outfide much lighter. It grows in form of a bufh, with a multitude of fmall branches rifing immediately from the ground, and is generally feven or eight feet high. Our author faw it when in flower only, never when bearing fruit. It has a very ftrong fmell, refembling that of the fmall fcented flower called mignionet, fown in vafes and boxes in windows, or rooms, where flowers are kept.

Our author reprefents the kantuffa as fo very troublefome, that it renders travelling through fome places of Abyffinia almoft impoffible. The foldier fcreens himfelf from it by a goat's, a leopard's, or a lion's fkin thrown over his fhoulder, of which it has no hold. As his head is bare, he always cuts his hair fhort before he goes to battle, left his enemy fhould take advantage of it, but the women, wearing their hair long, and the great men, whether in the army or travelling in peace, being always clothed, it never fails to incommode them, whatever fpecies of raiment they wear. If their cloak is fine muflin, the leaft motion againft it puts it all in rags; but if it is a thick, foft cloth, as thofe are with which men of rank generally travel, it buries its thorns, great and fmall, fo deep in it, that the wearer muft either difmount and appear naked, which to principal people is a great difgrace, or elfe much time will be fpent before he can difengage himfelf from its thorns. In the time when one is thus employed, it rarely fails to lay hold of you by the hair, and that again brings on another operation, full as laborious, but much more painful, than the other. A proclamation is therefore iffued, every year immediately before the king commences any march, in thefe words; "Cut down the kantuffa in the four quarters of the world; for I do not know where I am going." The wild animals, both birds and beafts, efpecially the Guinea fowl, know how well it is qualified to protect them. In this fhelter, the hunter in vain could endeavour to moleft them, were it not for a hard-haired dog, or terrier of the fmalleft fize, who being defended from the thorns by the roughnefs of his coat, goes into the cover, and brings them and the partridges alive one by one to his mafter.

Kappas, Kaffon.

KAPPAS, a tribe of Illinois Indians, in Louifiana: they lie a little above the Sothouis. This nation was formerly very numerous before the difcovery of the Miffiffippi. The country they inhabit has good paftarage.—*Morse.*

KAPPAS *Old Fort*, in Louifiana, ftands on the Miffiffippi, at the mouth of the river St Francis. It was built by the French principally for a magazine of ftores and provifions, during the wars with the Chicafaws; by whom their Illinois convoys were conftantly attacked and frequently deftroyed.—*ib.*

KARATUNK, or *Carytunk*, a plantation in Lincoln county, Diftrict of Maine, confifting of about 20 families or 103 inhabitants. It is the uppermoft on Kennebeck river, 14 miles north of Brookfield.—*ib.*

KASKASKIAS *Village* lies on the S. W. bank of the river of the fame name, a water of the Miffiffippi, in the N. W. Territory, oppofite Old Fort, and 12 miles from the mouth of the river, but not half that diftance from the Miffiffippi. It contains 80 houfes, many of them well built; feveral of ftone, with gardens, and large lots adjoining. About 20 years ago it contained about 500 whites, and between 4 and 500 negroes. The former have large ftocks of black cattle, fwine, &c.—*ib.*

KASKASKIAS, an Indian nation near the river of their name in the N. W. Territory. They can furnifh 250 warriors. Three miles northerly of Kafkafkias is a village of Illinois Indians, of the Kafkafkias tribe, containing about 210 perfons, and 60 warriors. They were formerly brave and warlike, but are now degenerated and debauched. At the late peace, the United States granted them a fum of money in hand, and became bound to pay them 500 dollars a year forever. —*ib.*
